# DANA'S
# SERIES OF MINERALOGIES.

### NEW "SYSTEM OF MINERALOGY."

Embodying the results of the last 24 years of active progress. Containing more than half more matter than the former edition and the page increased one-fifth in size. Not merely revised but entirely rewritten. Sixth edition, 1892.............................1197 pp., 1425 Cuts, $12 50

### FIRST APPENDIX TO THE SIXTH EDITION OF DANA'S SYSTEM OF MINERALOGY.

Completing the work to 1899..........................Cloth, 1 00

### MANUAL OF MINERALOGY AND PETROGRAPHY.

Containing the Elements of the Science of Minerals and Rocks, for the use of the Practical Mineralogist and Geologist, and for Instruction in Schools and Colleges. By Jas. D. Dana, LL.D. Twelfth edition. Illustrated with numerous woodcuts....................12mo, cloth, 2 00

### A TEXT-BOOK OF MINERALOGY.

With an Extended Treatise on Crystallography and Physical Mineralogy. By Edward Salisbury Dana, Professor of Physics and Curator of Mineralogy, Yale University. New edition, entirely rewritten and reset. With nearly 1000 figures and a colored plate........8vo, cloth, 4 00

### CATALOGUE OF AMERICAN LOCALITIES OF MINERALS.

Reprinted from sixth edition of the System...8vo, cloth, 1 00

### MINERALS, AND HOW TO STUDY THEM.

A book for beginners in Mineralogy. By Prof. E. S. Dana.....................................12mo, cloth, 1 50

ALSO

### A TEXT-BOOK OF ELEMENTARY MECHANICS.

For the Use of Colleges and Schools. By Prof. E. S. Dana.....................................12mo, cloth, 1 50

LONDON: CHAPMAN & HALL, LIMITED
1904.

ROBERT DRUMMOND, ELECTROTYPER AND PRINTER, NEW YORK.

# PREFACE.

NEARLY twenty-four years have passed since the last edition of this work was published; a long period, and one in which the science of Mineralogy has made very rapid progress. In fact, this quarter-century has probably been a time of more active mineralogical investigation than any like period in the past. A striking indication of this is given by the many new periodicals, recently started, which are devoted largely if not exclusively to Mineralogy. These include: Groth's Zeitschrift, started in 1877, of which the 19th volume is just completed; Tschermak's Mittheilungen, begun in 1872; the French Bulletin, begun in 1878; the English Mineralogical Magazine, begun in 1876; the Förhandlingar of the Swedish Geological Society, begun in 1872; the Italian journals, the Rivista di Mineralogia, begun in 1887, and the Giornale di Mineralogia, begun in 1890. Further the St. Petersburg Mineralogical Society, which published nothing for a number of years, commenced again with a new series in 1866 and has issued an annual volume regularly since then. Moreover, the always valuable Jahrbuch für Mineralogie has more than doubled its size.

This catalogue of new periodicals, which might be further extended, is a striking proof of the activity of mineralogical workers since 1868. Further evidence of this is given by the fact that within this time nearly one thousand new names have been introduced into the science—unfortunately not all "new species," although this has been claimed for most of them.

Still again, it is only within this period that the importance of the optical investigation of minerals has been fully recognized and the methods and instruments for optical and microscopical study have been developed and brought within the reach of all mineralogical observers. New means of observation have not only increased our knowledge of the optical constants of many species, but have developed new views in regard to the molecular structure of crystals. In Chemical Mineralogy, also, there has been rapid progress; on the theoretical side, in the way of explaining the composition of complex species and groups of species; again on the analytical side, and perhaps even more by the development of the synthetic processes. The last mentioned methods, in the hands of skillful chemists, have resulted in the reproduction in the laboratory of most of the prominent mineral species, as the feldspars, quartz, the pyroxenes and chrysolites, amphibole, corundum, etc.; thus throwing much light upon the composition of species and their formation in nature. The work in this field is almost all of recent date.

It is not strange, then, that this volume should contain more than half more matter than the former edition; indeed, it has only been with a rigid system of abbreviation and condensation, aided by an increase of one-fifth in the size of the page, that it has been kept down to this limit.

The broad and solid foundation laid in the previous edition has made it possible to undertake here a greater degree of thoroughness and completeness than was possible before. The careful work on the history of mineral species, shown in the tracing out to the original source of their many names, was so well and fully done that it stands now essentially as it did in 1868. In other words, the list of synonyms, with references to the first authority, has been adopted entire from the 5th Edition. Such additions, however, as the period has served to introduce have been made, and also there have been added many common names of important species used in the other prominent languages besides English, German, and French. This last feature it is hoped will add much to the general usefulness of the work.

The crystallographic portion of the subject has called for more than a mere revision. Here it has been the attempt, in the first place, to trace back to the original observer the fundamental angles for each species,—not always an easy task,—then the axes have been recalculated from them, and finally the important angles for all common forms have been calculated from these axes. In view of the too common practice of copying angles calculated by another without noting the source from which they have been taken, it is fair to state that every angle here given has been calculated anew for this work without exception; further, where there has been no other independent means of verification at hand, the angles have in most cases been calculated a second time independently. In this way, it is hoped that a fair degree of accuracy has been attained, although the author is keenly aware of the many ways in which errors can creep in, particularly in the case of a work which has so slowly and with so many interruptions approached completion, and where the progress of the science has made new calculations and new lists of forms so often necessary.

The lists of forms have been made up as completely as possible from the original authorities, but doubtful forms and those that seem to be merely of a vicinal character are usually separated from the main list. The forms are denoted by letters in all cases, and the symbols are given on both the systems of Miller and Naumann, though the preference is given to the former, which should, indeed, finally supplant the others. In the hexagonal and rhombohedral systems, the commonly adopted symbols of Miller-Bravais are employed, instead of the rhombohedral symbols of Miller.

References to the authors are given freely; and it is intended that these, with the others relating to the history of the names, and further those in connection with the lists of analyses, shall present a fairly complete literature, in compact form, for each species. Where, in the case of common species, the literature is very voluminous and has been carefully worked up by some author, this source of minuter detail is also indicated.

Of the figures, about 1400 in number, all but very few of those in the body of the work have been made anew. A large part, particularly those illustrating American species, have been drawn from original data, and where figures are taken from other authors—as is done freely—it is intended in all cases to give the source; in these cases, too, they have in large part been redrawn to insure uniformity of projection.

The habits of the crystals, methods of twinning, and the physical characters, especially those on the optical side, have been carefully rewritten and in general are given with much fullness. In regard to the optical constants, however, the object has been rather to give standard determinations than to overload the book with a multitude of measurements of all grades of accuracy.

In regard to the matter of classification, chemical formulas, and related points, reference may be made to the explanation given in the Introduction for the principles adopted. It may be stated, however, that it has been the plan to develop as clearly as possible the successive groups of species and the characters belonging to them.

In the lists of analyses, the plan has been to give all that are useful for a complete understanding of the composition of each species. This means all reliable analyses in the case of the rare species or those of complex composition. In many cases, however, particularly when rare elements are involved, the old analyses have been largly superseded, in consequence of the more accurate results of new chemical methods; for them, therefore, the reader is referred to the former edition. Still again, in the case of many common species where the analyses have developed almost indefinitely (e.g., feldspars, pyroxene, garnet, etc.), the aim has been to select recent analyses and those that best represent the composition; references are often given to other sources where additional analyses may be found. Analyses which are of purely technical character, as, for example, those showing the amount of impurity in iron ores, do not fall within the scope of this work.

The clear development of the varieties of a species in their proper relation to each other and to the main species, which was one of the excellent features of the last edition, has been carried through as far as possible in the same way. In regard to the line between varieties and species, no law can be laid down and individual opinions must differ. The author believes, however, that while a small percentage of a foreign element does not give the variety the place of a species, still the two extremes of a series, between which many gradations exist, it is well to regard as distinct,—e.g., Tetrahedrite and Tennantite,—and this principle has been followed throughout. At the same time, the description is given in such a form as to show as clearly as possible their mutual dependence. The Garnets are made subspecies, like the forms of common monoclinic Pyroxene and Amphibole, but they have much claim to be regarded as distinct.

The line between well defined species and those which are placed in a subordinate position, until further investigated, must also be more or less arbitrarily drawn. Many so-called species, which have long been so regarded, are here deprived of that rank, and probably more might fairly have received the same treatment. Of the multitude of new names recently introduced, but few comparatively are based upon complete, satisfactory investigations. Certainly now that the means of mechanical purification of material for analysis by heavy solutions are so convenient and accurate, and still more since microscopic examination is so well understood, there is little excuse for loading the science down with names based on descriptions faulty and incomplete. A new name for a well characterized variety, announced as such, may be useful; a new name for what may with reasonable certainty be regarded as a new species, even if at the time the material is too scanty to allow of analysis, may be an advantage. But names hastily given to imperfectly described "species," based often upon an imperfect analysis of material of more than doubtful purity, are a serious hindrance to science.

The subject of the general occurrence and association of the species has been considerably developed. It has not been attempted to give an exhaustive statement of localities, however. To have done this would have been to have doubled the size of the volume. The localities are given with much fullness for this country and are to be supplemented by the Catalogue of American Localities at the end of the volume, which, thanks to the assistance of a number of gentlemen, has been made much more complete and accurate than heretofore. For foreign localities, the list is brief but is intended to include those that are most important and typical. The parts of the admirable new Mineralogy of Hintze leave little in this direction to be desired.

All crystallographic and physical data, analyses, etc., have either been taken direct from the original authority or have been verified from it. References given mean, therefore, authors actually consulted; this is distinctly stated, for the practice of quoting at second hand while giving the original reference is as common as it is bad in its results. In the few cases where the original authority has not been accessible this is often given in brackets [ ], while the actual source follows. The only limitation to the above statement concerns the literature connected with the synonyms, where the references are reproduced for the most part from the previous edition, with only such verification as the most important have called for. Other points in regard to the methods followed will be found explained in full in the Introduction.

In the spelling of foreign geographical names the author has attempted to follow a system, chiefly that laid down not long since by the Royal Geographical Society of London, in which, briefly, the consonants have the same value as in English, while the vowels have the Continental (Italian) sounds. The transliteration of Russian names has been the most difficult part of the matter, and here the author most gratefully acknowledges his indebtedness to Mr. J. Sumner Smith of the Yale University Library, whose valuable advice has been always freely given and except in one or two particulars uniformly followed. That a reform is needed in this direction is most obvious, for it is little creditable to the English language that it alone should have no independence, but should follow now a French, now a German method according to the source from which the word has been absorbed—probably both methods more or less at variance with its own usage. The subject is a difficult one, however, and it is doubtful whether a system, satisfactory in all respects, can be devised. Reference may be made here to a paper on the subject in Nature (Feb. 27, 1890) which throws much light upon the subject.

The literature of the science has been freely drawn upon, especially that of the past twenty-five years. No better acknowledgment is needed to the many faithful workers, who have made the science what it is to-day, than the frequent references to their names which are to be found on almost every page of this work: to mention them individually seems quite unnecessary.

The published works of many authors have been also used freely—among these no one has been more useful than the Mineralogy of Brooke and Miller (1852) as revised, on the crystallographic side, by Prof. W. H. Miller. From this admirable volume many hints have been taken. The Russian Mineralogy of Koksharov, the Atlas of Schrauf, the Crystallography of Sadebeck, and many others have been used constantly. The Index of Goldschmidt has been useful in the verification of lists of forms, though these were made out (up to date) before the first part appeared in 1886. On the optical side, use has been made particularly of Des Cloizeaux's

Mineralogy and his other extensive memoirs, also the recent work of Lévy and Lacroix; but many other authors have also yielded valuable material.

In the chemical part of the subject, Rammelsberg's Mineralchemie has been, as before, of great value, while the Tables of Groth have given many suggestions as to the formulas and chemical relations of the species; the papers of Tschermak and Clarke have also been very useful.

In the great labor involved in the preparation of this work, the author has had the assistance of many gentlemen to whom his thanks are returned even if they are not mentioned by name. First of all, his acknowledgments are due to Prof. James D. Dana, the author of this System of Mineralogy from 1837 to 1868, and to whom all its chief points of excellence are due. His encouragement and advice have always been ready, but unfortunately ill health interrupted his plan of following it in detail as it was passing through the press. To Prof. G. J. Brush also the author is indebted for many friendly words of counsel. One of the most valuable features of the last edition was the full account of the blowpipe and allied characters of species, prepared by him, and this has been reproduced here almost without change. Prof. Penfield has stood in still closer connection with the work; much of the proof has passed under his eye, and, besides many suggestions on minor points, he has supplied from his own observations and work much original matter not yet published. Numerous analyses, figures of crystals, etc. (especially under amphibole and pyroxene), have been given by him from a memoir on the minerals of Northern New York, soon to be published as a Bulletin of the U. S. Geological Survey. The permission to use this matter in advance the author owes to the courtesy of Major Powell, Director of the Survey.

To Dr. Genth of Philadelphia, ever active in the investigation of American minerals, the author's thanks are due for new matter supplied from his unpublished notes, for corrections to the former edition, and still more for assistance in regard to the mineral localities in Pennsylvania and North Carolina. Prof. F. W. Clarke has also been most friendly in like directions; while for the difficult subject of American localities, a number of gentlemen have made valuable contributions whose names are mentioned in full on p. 1053. To Prof. F. A. Gooch of New Haven, Dr. W. F. Hillebrand of Washington, Dr. G. H. Williams of Baltimore, Prof. J. C. Branner of Little Rock, Arkansas, Dr. E. O. Leech of the U. S. Mint, Mr. H. S. Durden of San Francisco, Mr. G. Chr. Hoffmann of Ottawa, and other gentlemen the author is also indebted.

Among the Mineralogists abroad, to whom the author owes especial acknowledgment, he would mention Prof. W. J. Lewis of Cambridge, England, Mr. L. Fletcher of the British Museum, Professors Paul Groth of Munich and G. Tschermak of Vienna, whose advice at the beginning of the work was most valuable, as also the aid that they have given since then. Mr. Thomas Davies of the British Museum kindly furnished a list of minor errors that had before escaped notice in the 5th Edition, and these it is hoped have not been perpetuated here. To Prof. A. Des Cloizeaux, W. C. Brögger of Stockholm, N. von Koksharov of St. Petersburg, and others, the author would also express his indebtedness. Through the kindness of Prof. Brögger, advance sheets of his noble work on the minerals of the augite- and nephelite-syenite of Southern Norway were received in time to be freely used.

In two directions the author has been able to make use of clerical assistance. First, in the calculations of angles from the accepted axes, for in general only the recalculation when necessary for the sake of verification has been assumed by the author. Here Miss Charlotte C. Barnum of New Haven, from 1885 to 1887, and Prof. H. H. White of Neligh, Nebraska, from 1886 to the end, have rendered most valuable aid. Second, in the drawing of crystals, the author has been most efficiently aided by Mr. E. F. Ayres, also by Mr. L. V. Pirsson, and further by Prof. E. H. Barbour, Dr. E. O. Hovey, Dr. F. W. Mar, and Messrs. J. Stanley-Brown, O. C. Farrington, E. W. Goodenough, F. D. Leffingwell, John Leverett, Edward Cramer, and others.

Finally, the author takes pleasure in expressing his appreciation of the liberal support of the publishers, Messrs. John Wiley & Sons, and also of the patient care with which the printers and engravers have carried through a work of more than usual labor and vexation.

In conclusion, the author would express the hope that he may be informed of errors, great or small, noted by those using the book, in order that they may be corrected in future printings from the stereotype plates. It is intended to keep the work up to date, by the publication of appendixes at not very long intervals.

EDWARD SALISBURY DANA.

NEW HAVEN, CONN., *January* 1, 1892.

# EXTRACTS FROM THE PREFACES OF THE FORMER EDITIONS OF THIS WORK BY JAMES D. DANA.

## FROM THE PREFACE TO THE FIRST EDITION (1837).

* * * * * The classification of the mineral species, which is here adopted, is strictly a *Natural* Arrangement. The superiority of this method is exhibited in the body of the work, and in connection with the remarks on Chemical Classifications, in Appendix B. Although founded by Mohs on the external characters of minerals, it exhibits, in a considerable degree, the chemical relations of the species; and those who are accustomed to prefer a chemical arrangement will probably perceive that, in addition to such qualities as appear to recommend the chemical method, it possesses other advantages not less important.

The changes which have been made in the nomenclature of minerals appear to be demanded by the state of the science. The present names, excepting those proposed by Mohs, are utterly devoid of system, unless we may consider such the addition of the syllable *ite* to words of various languages; and even this glimmering of system has been capriciously infringed by a French mineralogist of much celebrity—they seldom designate any quality or character peculiar to the mineral; neither do they exhibit any of the general relations of the species, by which the mind may, at a glance, discover their natural associations, and be assisted in obtaining a comprehensive view of the science. On the contrary, they are wholly independent, and often worse than unmeaning, appellatives, and are only tolerable in a very unadvanced state of the science. As a necessary consequence of this looseness of nomenclature, most of the species are embarrassed with a large number of synonyms, a fertile source of confusion and difficulty.

As a remedy for this undesirable state of things, a system of nomenclature, constructed on the plan so advantageously pursued in Botany and Zoology, was proposed by the author in the fourth volume of the Annals of the New York Lyceum. The necessity for something of the kind is very apparent, and the author trusts that it will not be considered a needless innovation. * * * * *

## FROM THE PREFACE TO THE SECOND EDITION* (1844).

The natural system adopted in this treatise has received such modifications in the present edition as were demanded by the advanced state of the science; and the systematic nomenclature has required some corresponding changes.

Besides the natural classification, another, placing the minerals under the principal element in their composition, has been given in Part VII; and various improvements on the usual chemical methods have been introduced, which may render it acceptable to those that prefer that mode of arrangement. * * * * *

## FROM THE PREFACE TO THE THIRD EDITION (1850).

This treatise, in the present edition, has undergone so various and extensive alterations that few of its original features will be recognized. The science of Mineralogy has made rapid progress in the past six years; chemistry has opened to us a better knowledge of the nature and

---

* This edition, failing to find a publisher in New York, was printed at the expense of the author.

relations of compounds; and philosophy has thrown new light on the principles of classification. To change is always seeming fickleness. But not to change with the advance of science is worse; it is persistence in error; and, therefore, notwithstanding the former adoption of what has been called the Natural History System, and the pledge to its support given by the author in supplying it with a Latin nomenclature, the whole system, its classes, orders, genera, and Latin names, have been rejected; and even the trace of it which the synonymy might perhaps rightly bear has been discarded. The system has subserved its purpose in giving precision to the science, and displaying many of the natural groupings which chemistry was slow to recognize. But there are errors in its very foundation, which make it false to nature in its most essential points; and, in view of the character of these errors, we are willing it should be considered a relic of the past.

Yet science is far from being ready with an acceptable substitute. Most *chemical* systems have been more artificial than the "natural" system; and doubts now hang over some of the principles of chemistry that are widest in their influence on classification. In view of the difficulties on either side, it was a point long questioned, whether to venture upon a classification that might be deemed most accordant with truth among the many doubts that surround the subject; or to adopt one less strict to science, that might serve the convenience of the student for easy reference, and for the study of mineralogy in its economical bearings, while, at the same time, it should exhibit many natural relations, and inculcate no false affiliations or distinctions of species. The latter alternative has been adopted;—the classification is offered simply as a convenient arrangement, and not an exhibition of the true affinities of species in the highest sense of the term. Among the Silicates, however, it will be perceived that the groupings in the main are natural groupings; and, throughout the work, special care has been taken to inculcate, as far as possible, the true relations of species, both by remarks, and by an exhibition of them in tables. * * * * *

## FROM THE PREFACE TO THE FOURTH EDITION (1854).

In the Preface to the last edition of this treatise, the classification of minerals then adopted was announced as only a temporary expedient. The system of Mohs, valuable in its day, had subserved its end; and in throwing off its shackles for the more consistent principles flowing from recent views in chemistry, the many difficulties in the way of perfecting a new classification led the author to an arrangement which should "serve the convenience of the student without pretending to strict science."

A classification on chemical principles was however proposed in the latter part of the volume, in which the Berzelian method was coupled with crystallography in a manner calculated to display the relations of species in composition as well as form, and prominently "exhibit the various cases of isomorphism and pleomorphism among minerals." The progress of science has afforded the means of giving greater precision and simplicity to this arrangement, until now it seems entitled to become the authorized method of a System of Mineralogy. Whether regarded from a physical or chemical point of view, the groupings appear in general to be a faithful exhibition of the true affinities of the species.

The mind uneducated in science may revolt at seeing a metallic mineral, as galena, side by side with one of unmetallic luster, as blende; and some systems, in accordance with this prejudice, place these species in separate orders. Like the jeweler, without as good reason, the same works have the diamond and sapphire in a common group. But it is one of the sublime lessons taught in the very portals of chemistry, that nature rests no grand distinctions on luster, hardness, or color, which are mere externals, and this truth should be acknowledged by the mineralogist rather than defied. Others, while recognizing the close relations of the carbonates of lime, iron, zinc, and manganese (calcite, spathic iron, smithsonite, and dialogite), or of the silicates of lime, iron, manganese (wollastonite, augite, rhodonite), are somewhat startled by finding silicate of zinc, or silicate of copper, among the silicates of the earths, or of other oxyds. But the distinction of "useful" and "useless," or of "ores" and "stones," although bearing on "economy," is not science. * * * * *

## FROM THE PREFACE TO THE FIFTH EDITION (1868).

The large size of this volume on Descriptive Mineralogy, exceeding by one-half the corresponding part of the preceding edition, is not without good reason.

In the first place, the long interval of fourteen years has elapsed since the last edition was published, and during this period the science has made great progress. Chemical researches have been carried forward in connection with almost every species, and analyses have been largely multiplied; and it is the plan of the work to be complete in this department, so far as to include all analyses. Crystallographic investigations also have been numerous and important. Moreover, the number of species has been much enlarged, and every part of the science has had accessions of facts.

In addition, a new feature has been given the work, in the systematic recognition and description of the *varieties* of species. The first edition of this treatise, that of 1837, was written in the spirit of the school of Mohs. The multitudes of subdivisions into subspecies, varieties, and subvarieties, based largely on unimportant characters, which had encumbered the science through the earlier years of this century, and were nearly smothering the species, were thrown almost out of sight by Mohs, in his philosophic purpose to give prominence and precision to the idea of the species. Much rubbish was cleared away, and the science elevated thereby; but much that was necessary to a full comprehension of minerals in their diversified states was lost sight of. In the present edition an endeavor is made to give varieties their true place; and to insure greater exactness with regard to them, the original locality of each is stated with the description.

Further, the work has received another new feature in its historical synonymy. A list of synonyms has hitherto been mainly an index to works or papers on the species, and often without any regard to the original describer or description. Hausmann's admirable Handbuch (1847) is partly an exception. Leonhard's "Oryktognosie" (1821, 1826), following the method of Reuss of the opening century, contains a full catalogue of references to publications on each species; but it fails of half its value because the references have no connection in any way with the synonymy. In most recent works, an author who has merely adopted a name is often quoted as if the original authority. The present work is no longer open to this criticism. As now issued, the first author and first place of publication of each species, and of each name it has borne, and of the names of all its varieties, are stated in chronological order, with the dates of all publications cited; and, besides, remarks are added in the text when the subject is one of special interest. The facts and conclusions have been derived in almost all cases from the study of the original works themselves; and this treatise has become thereby, to some extent, an account of ancient as well as modern minerals. These historical researches added a third to the labor of preparing the edition for the press, thereby delaying the publication of the work about a year. But such studies are endless, especially when they relate to past centuries, and the work, however long continued, must be incomplete. * * *

* * * In these and other ways the volume has unavoidably become enlarged. Not a page, and scarcely a paragraph, of the preceding edition remains unaltered, and full five-sixths of the volume have been printed from manuscript copy. I may here add that, notwithstanding the impaired state of my health, this manuscript—the paragraphs on the pyrognostic characters excepted—was almost solely in the handwriting of the author, or in that of a copyist from it. Neither the consultation of original authorities, the drawing of conclusions, nor the putting of the results on paper, has been delegated to another. And being now but half-way between the fifties and sixties, it is my hope that the future will afford another opportunity for similar work.

* * * In classification, the general system remains unaltered. It is based on a comprehensive view of the characters of minerals as species in the inorganic kingdom of nature, the preëminence being given to chemical, the next place to crystallographic, the third to the different physical characters. The author believes (after having tried the so-called natural-history system of Mohs for two editions) that light from no source should be shut out where the relations of species and groups in nature are to be determined. As in the preceding edition, the method avoids almost entirely the distinction, in most cases wrong, founded on the fact of the base in

oxygen ternaries or salts being in the protoxyd state, or in the sesquioxyd, or in both combined, and proceeds on the ground that the basic elements in these and the other different states are mutually replaceable in certain proportions determined by their combining power with oxygen. But while the progress of chemistry and the kindred sciences requires no modification of the general plan of the classification, but gives it new support, it has rendered many minor changes necessary, and some that are of much importance.

The historical inquiries above alluded to were prompted by a desire to place the nomenclature of mineralogy on a permanent basis. They were incident to a search after a reason for choosing one name rather than another from among the number that stand as claimants. Part of the existing diversity is due to national partiality, and much of it to indifference. It has become somewhat common for authors to select the name they like best without reference to authority, or to reject an old for a new one on no other ground than that of their preference. Increasing confusion in nomenclature has consequently attended the recent progress of the science; and in view of this fact the novel expedient has been tried of endeavoring to escape the confusion by adding one more to the number of names. The right method is manifestly that which has proved so successful in the other natural sciences, viz., the recognition, under proper restrictions, of the law of priority; and this method the author has aimed to carry out.

Moreover, it has seemed best that the science should not only have a system of nomenclature, but should also stand by it; that, accordingly, the termination *ine*, which is prominently chemical, should be left to the chemists, and that other miscellaneous endings should, as far as possible, be set aside, or be made to conform to the system. With this in view, changes have been made in accordance with the principles explained in the course of the remarks beyond on Nomenclature. * * *

# TABLE OF CONTENTS.

# INTRODUCTION.

In the Description of Species the following order is observed:

**1. Name,** followed by synonyms in historical order with author, original reference, and date; also in many cases the common names in the forms peculiar to the French, German, Swedish, Italian and Spanish. See further on the subject of nomenclature, p. xl.

**2. Crystalline Form and Structure,** including (*a*) system of crystallization; (*b*) axial ratio and angular elements* with authority; (*c*) list of observed forms; (*d*) methods of twinning, general habit of crystals, and such details in regard to the character of individual faces as are of value, particularly in the orientation of the crystals. Also (*e*) general structure of crystalline, massive or amorphous varieties, imitative forms, and so on.

**3. Physical Characters.**—A. Those relating to COHESION, including (*a*) cleavage and parting; (*b*) fracture; (*c*) tenacity; (*d*) hardness (H).

B. SPECIFIC GRAVITY, or density referred to water (G).

C. Characters relating to LIGHT, including (*a*) luster; (*b*) color and streak, pleochroism and absorption; (*c*) degree of transparency; (*d*) special optical properties. These last include the positive (+) or negative (−) optical character; the position of the axial plane and bisectrix; the axial angle; dispersion; also the refractive indices, etc.

D. Characters relating to HEAT, ELECTRICITY, MAGNETISM.

E. TASTE and ODOR.

**4. Chemical Composition (Comp.).**—The chemical formula and percentage composition, followed, or sometimes preceded, by a description of the recognized varieties based upon form, structure, composition, etc. Then the analyses (**Anal.**) with references to the original authorities.

**5. Pyrognostic** characters, or those determined by the use of the blowpipe and similar means; also other related chemical characters (**Pyr., etc.**).

---

* In general it is intended to give the values of the axes to within three or four units in the fifth decimal place, in which case the calculated angles should be correct at least within 10″. When the accuracy of the fundamental angles seems to justify it, a greater degree of exactness is employed, so that the calculated angles may be correct to 1″. It is obvious that, unless in very exceptional cases, to give the axes to more than six decimals is merely playing with numbers.

The angular elements, which are intended to correspond to the axes in degree of accuracy, are those of the unit forms in the pinacoid zones, from which calculations may most readily be made. The fundamental angles are also indicated by an asterisk; when this is omitted the axial ratio of the original author (often deduced by method of least squares) is taken as the starting point. The calculated angles are stated in general to the nearest minute, but the half-minute is often retained when the neglected seconds are near 30.

Mineralogy, Chemistry, etc., and to explain the special methods of notation, abbreviations, etc., adopted, some general explanations under these successive heads are given.

For fuller information on many of these points the reader is referred to the author's Text Book of Mineralogy, also to kindred works whose full titles are given in the Bibliography, thus on *Crystallography* and *Physical Mineralogy*, especially to the works of Groth, Mallard, Liebisch, Tschermak, G. H. Williams (Crystallography); also to others mentioned beyond under the special subjects.

## I. CRYSTALLOGRAPHY.

**Systems of Crystallization.**—There are six systems of crystallization, to one of which every crystal may be assigned; these are distinguished by the degree of symmetry characteristic of each, which usually finds expression in the statement of the lengths and mutual inclinations of certain axes assumed for the description of the form. These systems are:

1, ISOMETRIC; 2, TETRAGONAL; 3, HEXAGONAL and RHOMBOHEDRAL; 4, ORTHORHOMBIC; 5, MONOCLINIC; 6, TRICLINIC.

Other names which are or have been in common use are: for Isometric, cubic, regular; for Tetragonal, quadratic, dimetric; for Orthorhombic, rhombic, trimetric; for Monoclinic, monosymmetric or oblique; for Triclinic, asymmetric, doubly oblique, or anorthic.

Some general explanations applicable to all systems follow.

**Planes and Symbols.**—The position of a plane is fixed by its intercepts on the crystallographic axes, and is defined by its *symbol* which expresses the ratio of these intercepts to certain assumed *unit lengths* of the axes.

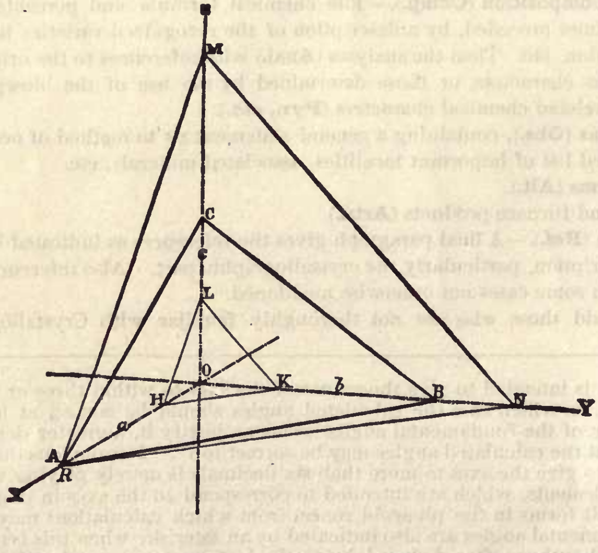
Thus, Fig. 1, let OA, OB, OC be taken as the unit lengths of the axes, and be represented by the letters $a$, $b$, $c$; the position of a plane RNM is fixed by its intercepts OR, ON, OM. If OR $= 1a$, OB $= \frac{4}{3}b$, OM $= 2c$, the ratio of the intercepts to the unit axes may be written for this plane:

$$1. \qquad 1a : \tfrac{4}{3}b : 2c.$$

For the plane HKL parallel to and hence crystallographically identical with RNM, the ratio is

$$2. \qquad \frac{a}{4} : \frac{b}{3} : \frac{c}{2}.$$

1.



It is found, in general, that if the lengths of the axes for any one plane be taken as the units, the ratio of those of every other plane on the same crystal (written as in 2) can be expressed by rational numbers and usually the whole numbers from 1 to 6 (or by 0).

The two forms

$$\begin{array}{ccc} 1. & & 2. \\ 1a : \tfrac{4}{3}b : 2c & \text{and} & \dfrac{a}{4} : \dfrac{b}{3} : \dfrac{c}{2} \end{array}$$

are identical, since the *ratio* of the axes is all that is important, not their absolute length. They further illustrate the symbols after the two common methods in use, those of Naumann and of Miller.

With Naumann the expression is always written in such a form that the multiple of one of the lateral axes (usually $a$) is unity (1) and the symbol,* written in the inverse order and omitting the axes, after Naumann's method, is then

$$2 : \tfrac{4}{3} : 1, \quad \text{or simply} \quad 2\text{-}\tfrac{4}{3}.$$

Similarly for other planes, whose intercepts written in the two methods are, respectively,

$$\begin{array}{cc} 1. & 2. \\ 1a : 1b : 2c & \dfrac{a}{2} : \dfrac{b}{2} : \dfrac{c}{1} \\ 1a : 2b : 1c & \dfrac{a}{2} : \dfrac{b}{1} : \dfrac{c}{2} \end{array}$$

the symbols are again, after Naumann, dropping the unity when it belongs to a lateral axis,

$$2 : 1 : 1, \quad \text{or simply} \quad 2.$$

$$1 : 2 : 1, \quad \text{“} \quad \text{“} \quad 1\text{-}2.$$

With Miller the expression is always taken in the equivalent form, 2 above, where the numerators are the unit lengths of the axes and the denominators are whole numbers; these three integers form then the *symbol* of the plane—that is, in the three examples given above, 432, 221, and 212.

The general symbol is *hkl*, corresponding to the full expression for any plane

$$\frac{a}{h} : \frac{b}{k} : \frac{c}{l}.$$

It will be seen that the symbols of Miller are essentially the reciprocals of those of Naumann. The minus signs, indicating intercepts of the negative lengths of the axes, are placed over the numbers to which they belong. The symbols employed in the hexagonal system are explained on a later page.

Naumann's symbols are further modified by writing the sign for infinity $\infty$ (in this book replaced by the initial letter *i*), and the omission of 1. Further, the lateral axes and the numbers referring to them are distinguished, for example in the orthorhombic system, where $\bar{b} > \breve{a}$, by a long and short mark.

Thus, for example :

| | | Naumann | | | Miller |
|---|---|---|---|---|---|
| $\breve{a} : 2\bar{b} : 2\grave{c}$ | becomes | $2\text{-}\bar{2}$ | or | $2P\bar{2}$ | 211 |
| $\breve{a} : 1\bar{b} : 2\grave{c}$ | “ | 2 | or | $2P$ | 221 |
| $\breve{a} : \infty\bar{b} : 2\grave{c}$ | “ | $2\text{-}\bar{i}$ | or | $2P\bar{\infty}$ | 201 |
| $\breve{a} : 1\bar{b} : \infty c$ | “ | *I* | or | $\infty P$ | 110 |
| $\breve{a} : 2b : \infty c$ | “ | $i\text{-}\bar{2}$ | or | $\infty P\bar{2}$ | 210 |

Some other modifications are mentioned in their proper place. It must be remembered that in Naumann's symbols, as stated above, the natural order is reversed and the first number (or infinity sign) refers always to the *vertical axis*.

Other systems of symbols, besides the two explained, have also been or still are in use, as those of Weiss, of Mohs and Haidinger, and of Hausmann, Lévy, Goldschmidt, and others. Of these the symbols of Weiss are essentially those already given (under 1, above) which abbreviated (and inverted in order) were adopted by Naumann. The symbols of Lévy are extensively

---

* Strictly Naumann's method makes this $2P\tfrac{4}{3}$, and in the other cases below $2P$, $P2$—that is, an initial $P$ is inserted after the number referring to the vertical axis in all but the isometric system, where the letter $O$ takes its place.

used by the French school of mineralogists. A very full explanation of all the different systems, as of that recently devised by himself, is given in Goldschmidt's Index (1886–1891). Transformation equations (for the important cases, in concise form) are given by Groth (Phys. Kryst.), Mallard (Crist., vol. 1), Liebisch (Kryst.), and others.

*A form* includes all the similar planes comprised in one general symbol. Thus if the three axes are unequal but at right angles (orthorhombic system) there are eight similar planes included in the general symbol *hkl* (or *m-n*) according as the axes are plus or minus, that is the form includes

| | | | |
|---|---|---|---|
| $hkl$ | $\bar{h}kl$ | $\bar{h}\bar{k}l$ | $h\bar{k}l$ |
| $hk\bar{l}$ | $\bar{h}k\bar{l}$ | $\bar{h}\bar{k}\bar{l}$ | $h\bar{k}\bar{l}$ |

For the form (211):

| | | | |
|---|---|---|---|
| $211$ | $\bar{2}11$ | $\bar{2}\bar{1}1$ | $2\bar{1}1$ |
| $21\bar{1}$ | $\bar{2}1\bar{1}$ | $\bar{2}\bar{1}\bar{1}$ | $2\bar{1}\bar{1}$ |

If, however, the axes *a* and *b* are equal (tetragonal system) the plane *hkl* and *khl* (or *a* : *na* : *mc* and *na* : *a* : *mc*) are similar and the form includes 16 planes; further, in the isometric system, where the axes (*a*) are all equal, a form may include 48 planes, while in the triclinic system it can include only 2 planes. This is further explained later under the different systems.

The *Law of Holohedrism* requires that *all* the planes of a given form should be present, that is all having the same general position with reference to the axes.

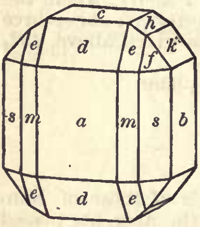
This law finds exceptions in:

*Hemihedrism*, where only half of the planes are present, but half selected according to a definite law; and in

*Tetartohedrism*, where only one-fourth of the possible similar planes are present.

A full explanation of these subjects is impossible in this place, but they are treated as fully as is practicable under the different systems.

2.



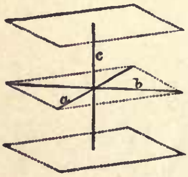
Some technical terms applied in the description of crystals require explanation.

*Pinacoid planes*, in general, are those which are parallel to two of the axes. These are designated in this work by the same letters as the axes at whose extremity they lie. Thus, fig. 2, *a*, *b*, *c* are the pinacoids having (in the orthorhombic system) the symbols:

| | Miller | Naumann | |
|---|---|---|---|
| *a* | 100 | *i*-ī | $\infty P\bar{\infty}$ |
| *b* | 010 | *i*-ĭ | $\infty P\breve{\infty}$ |
| *c* | 001 | *O* | $0P$ |

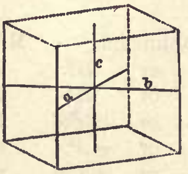
A *Prism* is a form whose planes are parallel to the vertical axis and intersect both the horizontal axes, if at the unit lengths it becomes the *unit prism* (having the symbol *I*) and in this work uniformly denoted by the letter *m*. In the several systems some additional terms, describing the different prisms, are introduced.

3.



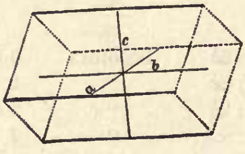
Basal Pinacoid.
(001, *O*)

4.



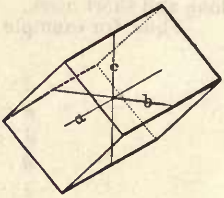
Prism.
(110, *I*)
(*hk*0, *i-n*)

5.



(101, 1-ī)
(*h*0*l*, *m*-ī)

6.



(011, 1-ĭ)
(0*kl*, *m*-ĭ)

Domes.

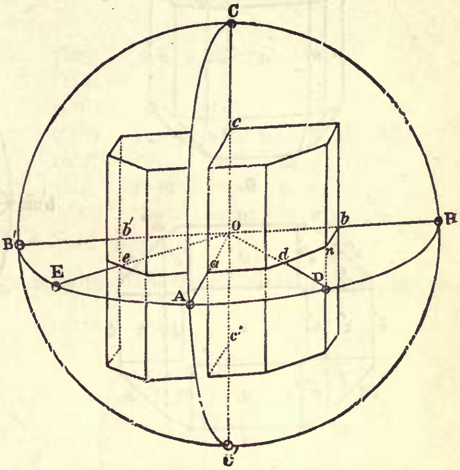
*Domes* are forms whose planes are parallel to one only of the lateral axes. They are specially named (macrodomes, clinodomes, etc.) in the different systems according to which axis they are parallel.

*Pyramids* are forms whose faces intersect the three axes; if the lateral axes at their unit lengths they are *unit pyramids*. In fig. 2, above, *a*, *b*, *c* are pinacoids ; *m* (110, *I*) and *s* (120, *i*-2̆) are prisms ; *d* (101, 1-ī) is a macrodome ; *h* (011, 1-ĭ) and *k* (021, 2-ĭ) are brachydomes, and *e* (111, 1), *f* (121, 2-2̆) are pyramids; cf. also figs. 3, 4, 5, 6.

*A zone* is a series of planes with mutually parallel intersections, since their parameters have all a constant ratio for two of the axes. The line through the center of the crystals to which the planes are parallel is the *zone-axis*. Familiar examples of zones, in part shown in fig. 2, are those of the prisms, $hk0$, of the domes, $h0l$ or $0kl$; also pyramids, as of the unit series $hhl$ (as 112, 111, 221) where $h = k$; or of any other zone as 211, 421, etc., where $h = 2k$; also 212, 111, 121, 131, where $h = l$, etc.

*Spherical Projection* —If the center of a crystal, that is, the point of intersection of the three axes, be taken as the center of a sphere, and normals be drawn from it to the successive planes of the crystals, the points, where they meet the surface of the sphere, will be the poles of the respective planes. For example, in f. 7 the common center of the crystal and sphere is at O, the normal to the plane $b$ meets the surface of the sphere at B, of $b'$ at B', of $d$ and $e$ at D and E respectively, and so on. These poles evidently determine the position of the plane in each case.

7.



After Brezina.

It is obvious that the pole of the plane $b'$ ($0\bar{1}0$) opposite $b$ (010) will be at the opposite extremity of the diameter of the sphere, and so in general, (120) and ($1\bar{2}0$), etc. It is seen also that all the poles, or normal points, of planes in the same *zone*, that is, planes whose intersection-lines are parallel, are in the same great circle, for instance the planes $b$ (010), $d$ (110), $a$ (100), $e$ ($1\bar{1}0$), and so on.

It is customary in the use of the sphere to regard it as projected upon a horizontal plane, usually that normal to the prismatic zone, so that, as in f. 10, the prismatic planes lie in the circumference of the circle, and the other planes within it. The eye being supposed to be situated at the opposite extremity of the diameter of the sphere normal to this plane, the great circles then appear either as arcs of circles, or as straight lines, i.e., diameters.

It will be further obvious from f. 7 that the arc BD, between the poles of $b$ and $d$, measures an angle at the center (BOD), which is the supplement of the actual interior angle $bnd$ between the two planes.

In the construction of the spherical projection, it must be noted that the poles on the circumference are fixed directly by the angles measured by a protractor, while the positions of 101 on the zone-circle 100, 001, $\bar{1}00$ and of 011 on 010, 001, $0\bar{1}0$ are fixed by the fact that the distances to them from the center of the circle (here 001) are proportional to the *tangents of half the angles* of 001 ∧ 101 and 001 ∧ 011, and this holds true in general. Furthermore, it must be noticed that the pole 111 is situated at the intersection of the zone-circles 001 and 110, 100 and 011, 010 and 101; so in general $hkl$ at the intersection of 001 and $hk0$, 100 and $0kl$, 010 and $h0l$.

*Horizontal Projections.*—In addition to the usual perspective figures of crystals, projections usually on the basal plane (or more generally the plane normal to the prismatic zone) are freely used, and in these the successive planes are indicated by accents, passing around in the direction of the axes $a$, $b$, $c$, that is counter-clockwise. Thus compare the figures below, 8 and 9 and the spherical projection, f. 10. These methods are modified somewhat to meet the demands of the different systems.

*Angles between Planes.*—The angles given in this work are always the *normal angles*, that is the angles between the poles or normals to the planes, measured on the arc of a great circle joining the poles as shown on the spherical projection (f. 7, 10). These normal angles are the supplements of the actual interfacial angles, as has just been explained.

Furthermore, by reference to the projection, f. 10, it will be seen that the angle 100 ∧ 110, or (f. 9) *am*, is (in the orthorhombic system) half the angle 110 ∧ $\bar{1}10$ (*mm‴*). Similarly 010 ∧ 120 (*bs*) is half the angle 120 ∧ $\bar{1}20$ (*ss'*); again, 100 ∧ 111 (*ae*) is the complement of half the angle 111 ∧ $\bar{1}11$ (*ee'*), and 010 ∧ 111 (*be*) the complement of half the angle 111 ∧ $1\bar{1}1$ (*ee‴*).

Further:

100 ∧ 010 (*ab*) = 100 ∧ 110 (*am*) + 110 ∧ 120 (*ms*) + 120 ∧ 010 (*sb*)

Also:

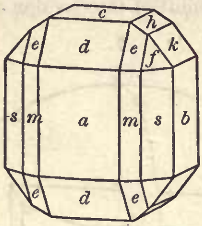
101 ∧ 010 (*db*) = 101 ∧ 111 (*de*) + 111 ∧ 121 (*ef*) + 121 ∧ 010 (*fb*).

Here, as throughout this work, the sign ∧ is used to designate the angle between two faces, usually designated by letters.

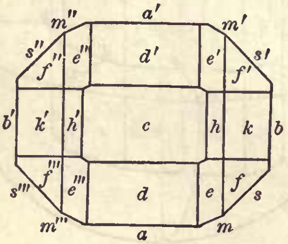
*Methods of Calculation.*—In general the angles between the poles can be calculated by the methods of spherical trigonometry from the triangles as shown in the sphere of projec [illegible] 10

—which for the most part are right-angled. Certain fundamental relations connect the axes with the elemental angles of the projection; the most important of these are given under the individual systems. For the formulas necessary in certain cases, reference must be made to works on crystallography.

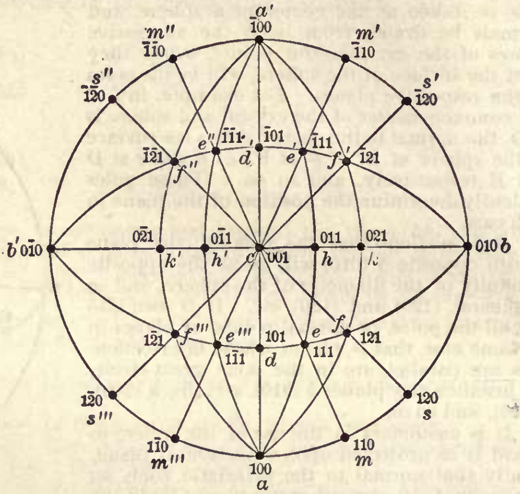
8.



9.



10.



The only relation which need be introduced here is the *tangent principle*, applicable to any zone between a pinacoid plane and a plane, 90° from this, in a zone with the other two pinacoids. The relation and its application to such zones will be evident from the following simple examples:

$$\frac{\tan\,(001 \wedge h0l)}{\tan\,(001 \wedge 101)} = \frac{h}{l}, \qquad \frac{\tan\,(001 \wedge 0kl)}{\tan\,(001 \wedge 011)} = \frac{k}{l},$$

$$\frac{\tan\,(010 \wedge hk0)}{\tan\,(010 \wedge 1\bar{1}0)} = \frac{h}{k}, \text{ or } \frac{\tan\,(100 \wedge hk0)}{\tan\,(100 \wedge 1\bar{1}0)} = \frac{k}{h}.$$

Also

$$\frac{\tan\,(001 \wedge hhl)}{\tan\,(001 \wedge 111)} = \frac{h}{l} \text{ or more generally } \frac{\tan\,(001 \wedge hhl)}{\tan\,(001 \wedge ppr)} = \frac{h}{l} \times \frac{r}{p}, \text{ etc.}$$

*Order of Forms.*—In the lists of forms under each species, the following order is followed:

1. Pinacoids, 100, 010, 001;
2. Prisms, commencing with the form ($hk0$) nearest 100;
3. Domes, commencing with the forms ($h0l$ and $0kl$) nearest to 001;
4. Pyramids of the unit series in a like order;
5. Other pyramids arranged in vertical zones, e.g. from 001 to 210, etc., the zones being taken in the same order as that adopted above for the prisms. In the monoclinic system, the orthopyramids are given before the clinopyramids.

*Twin Crystals.*—A twin crystal is one in which one part is in reversed position with reference to the other, as if, in general, it had been revolved through 180° about a certain axis. This axis of revolution is the *twinning axis*, and the plane normal to it is the *twinning-plane;* either the twinning-axis must be a definite crystallographic line, or the twinning-plane a possible plane (usually a common one)—except in the inclined system both statements must hold true.

The plane common to the two crystals or parts of crystals in a simple *contact-twin* is the *composition-face;* it is usually the same as the twinning-plane, but may be normal to it. In a *penetration-twin* the parts may be united very irregularly.

Twinning may be repeated, giving rise to three-fold, four-fold, etc., compound crystals, called trillings, fourlings, fivelings, etc. This is common where the angle between the axes of the crystals in the twinning position is more or less closely an aliquot part of 180°; five-rayed, six-rayed, etc., star-shaped twins may result (cf. marcasite (p. 95), chrysoberyl (p. 229), rutile (pp. 237, 238).

Polysynthetic twinning is repeated twinning in the form of thin lamellæ alternately in reversed position with reference to each other; this usually produces fine lines or striations upon the bounding surfaces; cf. the triclinic feldspars, p. 326 *et seq.*

In twins the faces of the reversed part are denoted by a letter with a subscript line.

## 1. ISOMETRIC SYSTEM.

In the Isometric System there are three equal axes at right angles to each other. It is characterized (in the holohedral forms) by three principal planes of symmetry, all equal. The lines in which these planes of symmetry intersect are the crystallographic axes. There are also six auxiliary diagonal planes of symmetry, equal among themselves.

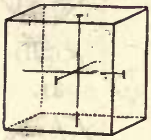
There are seven *holohedral* types of form in this system, that is seven in which *all* the similar planes comprehended by each general symbol are present. They are, in order of simplicity, with their symbols:

| | | | | |
|---|---|---|---|---|
| 1. Cube | (100) | *i-i* | ∞*O*∞ | *a* |
| 2. Octahedron | (111) | 1 | *O* | *o* |
| 3. Dodecahedron | (110) | *i* | ∞*O* | *d* |
| 4. Tetrahexahedron | (*hk*0) | *i-n* | ∞*On* | as *e* (210, *i*-2) |
| 5. Trigonal Trisoctahedron | (*hhl*) | *m* | *mO* | as *p* (221, 2) |
| 6. Tetragonal Trisoctahedron, or Trapezohedron | (*hll*) | *m-m* | *mOm* | as *n* (211, 2-2) |
| 7. Hexoctahedron | (*hkl*) | *m-n* | *mOn* | as *s* (321, 3-$\frac{3}{2}$) |

In the above $h > k > l$.

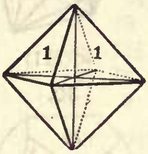
These forms are shown in the following figures with the symbols after both Miller and Naumann.

**11.**



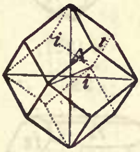
*a* (100, *i-i*)

**12.**



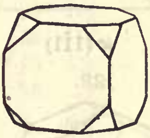
*o* (111, 1)

**13.**



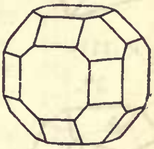
*d* (110, *i*)

**14.**



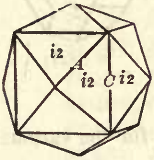
*a*, *o*

**15.**



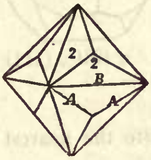
*a*, *o*, *d*

**16.**



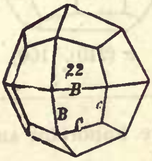
*e* (210, *i*-2)

**17.**



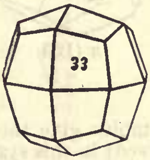
*p* (221, 2)

**18.**



*n* (211, 2-2)

**19.**



*m* (311, 3-3)

**20.**

*s* (321, 3-$\frac{3}{2}$)

The following letters are uniformly used in this work to designate the most commonly occurring forms, viz. (chiefly after Miller):

Cube *a*. Octahedron *o*. Dodecahedron *d*.

Tetrahexahedrons: $e = 210$, $i$-2; $f = 310$, $i$-3; $g = 320$, $i$-$\frac{3}{2}$; $h = 410$, $i$-4.

Tetrahexahedrons: $k = 520$, $i$-$\frac{5}{2}$; $l = 530$, $i$-$\frac{5}{3}$, $\vartheta = 430$, $i$-$\frac{4}{3}$.

Trigonal trisoctahedrons: $p = 221$, 2; $q = 331$, 3; $r = 332$, $\frac{3}{2}$; $\rho = 441$, 4.

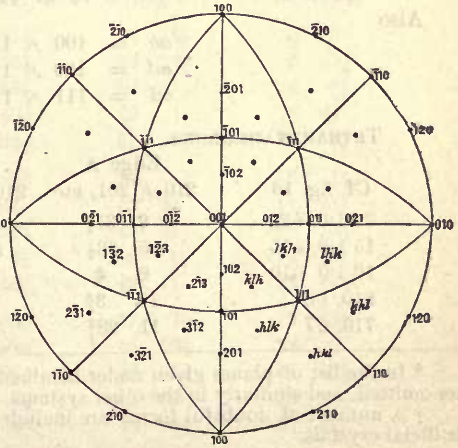
Tetragonal trisoctahedrons: $m = 311$, 3-3; $n = 211$, 2-2; $\beta = 322$, $\frac{3}{2}$-$\frac{3}{2}$.

Hexoctahedrons: $s = 321$, 3-$\frac{3}{2}$; $t = 421$, 4-2.

For other forms letters are used indiscriminately. The spherical projection, f. 21, shows the distribution of some of the forms of this system.

It will be noted that the planes of the hexoctahedron *s* (f. 20) in the right upper octant are, in order (counter-clockwise): 321, 231, 132, 123, 213, 312. Similarly for the trisoctahedron *p* (f. 17), 221, 122, 212; for *n* (f. 18), 211, 121, 112.

**21.**



The HEMIHEDRAL forms are those in which only *half* the normal number of planes are present. The common types are:

A. *Tetrahedral* or *Inclined hemihedrons.* Tetrahedron κ (111) or ½ (1), f. 22, 23.* Hemi-trigonal trisoctahedron κ (*hhl*) or ½ (*m*), f. 24, and hemi-tetragonal trisoctahedron κ (*hll*) or ½ (*m-m*). f. 25; hemi-hexoctahedron (hexatetrahedron) κ (*hkl*) or ½ (*m-n*), f. 26. Also

B. The *Pyritohedral* or *Parallel hemihedrons.* Pyritohedron π (*hk*0) or ½ (*i-n*), f. 27-30, and Diploid π (*hkl*) or ½ (*m-n*), f. 31.

There are also certain gyroidal or plagihedral hemihedrons (e.g., sylvite), and further tetartohedral forms which need not be explained here.

In general, hemihedrons may be plus or minus, according to which set of planes is present, thus:

The *plus* tetrahedron has the planes 111, $\bar{1}\bar{1}1$, $1\bar{1}\bar{1}$, $\bar{1}1\bar{1}$.
The *minus* " " " " $\bar{1}11$, $1\bar{1}1$, $11\bar{1}$, $\bar{1}\bar{1}\bar{1}$.

These are, in the majority of cases, represented by the same letters on the figures, but the minus or inverse form is indicated by a subscript accent, thus *o* (111, + 1) and $o_,$ ($1\bar{1}1$, − 1), and similarly of the other + and − hemihedral forms in this system.

---

* In the list of planes given under hemihedral species, these hemihedral signs κ and π, etc., are omitted, and similarly in the other systems.

† A number of doubtful forms are included in the lists, also some forms known only on artificial crystals.

**Tetrahexahedrons**—*Continued.*

| 15·15·2 | 51 7 | 68 41⅓ | 45 15¼ | 29 52⅔ |
| 881 | 51 40¼ | 68 9⅓ | 45 13⅓ | 30 12¾ |

---

* No distinction is made between the + and − forms; the angles are the same obviously except for the pyritohedrons and diploids, where the angle between a given + form (e.g., 210, 321) and 100 is the same as that for the corresponding − form (120, 231) and 010. The symbols after Naumann (many of them given in the table above) are omitted here.

## 2. TETRAGONAL SYSTEM.

In the Tetragonal System there are three axes at right angles to each other; two of these are equal (*a*); the third, the vertical axis (*ċ*), is longer or shorter. The system is characterized by three axial planes of symmetry, two of which are equal to each other; there are also two other auxiliary planes inclined 45° to the other pair.

The holohedral forms in this system are:

| | | | | |
|---|---|---|---|---|
| 1. Basal plane | (001) | *O* | 0*P* | *c* |
| 2. Diametral prism, or prism of second series | (100) | *i-i* | ∞*P*∞ | *a* |
| 3. Unit prism, or prism of first series | (110) | *I* | ∞*P* | *m* |
| 4. Ditetragonal prism | (*hk*0) | *i-n* | ∞*Pn* | as (210, *i*-2) |
| 5. Pyramids of diametral or second series | (*h*0*l*) | *m-i* | *mP*∞ | as *e* (101, 1-*i*), (201, 2-*i*), etc. |
| 6. Unit pyramids | (*hhl*) | *m* | *mP* | as (111, 1), (221, 2), etc. |
| 7. Ditetragonal pyramids or zirconoids | (*hkl*) | *m-n* | *mPn* | as (211, 2-2), (321, 3-$\frac{3}{2}$), etc. |

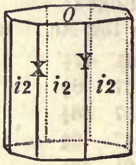
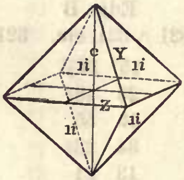
(001), (110)

34.



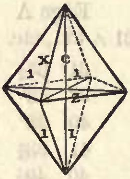
(001), (210)

35.



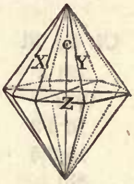
(101)

36.



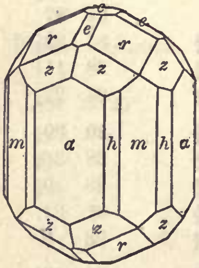
(111)

37

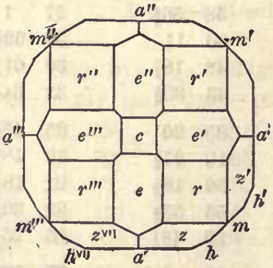


(*hkl*)

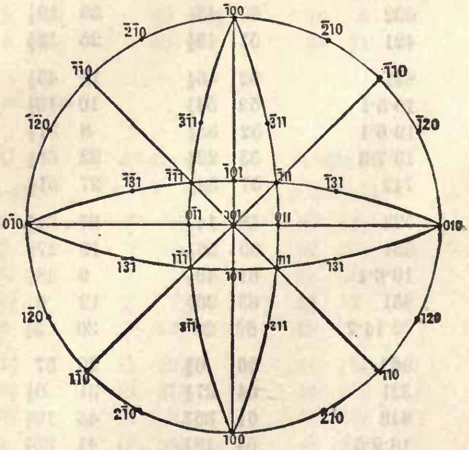
38.



39.



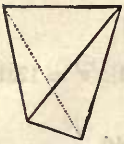
40.



In figs. 38, 39, *c* = (001), *a* = (100), *m* = (110), *h* = (210), *e* = (101), *r* = (111), *z* = (311).

These forms are shown in f. 32–37, and in combination in f. 38, of which f. 39, 40 are projections.

41.



π (111)

The *hemihedral* forms are:

A. *Sphenoidal* or inclined, represented by the sphenoid, or hemi-unit pyramid, f. 41, analogous to the tetrahedron (f. 22) and the tetragonal scalenohedron. Cf. figs. on pp. 80, 81, under chalcopyrite.

B. *Pyramidal,* including the half-form of the ditetragonal prism and pyramid or square prism and pyramid of the *third series.* Cf. figs. 3, 6, 7 under scheelite, p. 986, and f. 4–6, under wulfenite, p. 990.

The following table gives the important angles for the observed ditetragonal prisms, which are the same for all species. The angle of the edge X (f. 34) is twice the angle on *a* (100), and of the edge Y, twice the angle on *m* (110).

| | Angle on *a* (100, *i-i*) | Angle on *m* (110, *I*) | | Angle on *a* (100, *i-i*) | Angle on *m* (110, *I*) |
|---|---|---|---|---|---|
| 810, *i*-8 | 7° 7½′ | 37° 52½′ | 530, $i\text{-}\frac{5}{3}$ | 30° 57¾′ | 14° 2¼′ |
| 710, *i*-7 | 8° 7¾′ | 36° 52¼′ | 320, $i\text{-}\frac{3}{2}$ | 33° 41¼′ | 11° 18¾′ |
| 920, $i\text{-}\frac{9}{2}$ | 12° 31¾′ | 32° 28¼′ | 750, $i\text{-}\frac{7}{5}$ | 35° 32¼′ | 9° 27¾′ |
| 410, *i*-4 | 14° 2¼′ | 30° 57¾′ | 430, $i\text{-}\frac{4}{3}$ | 36° 52¼′ | 8° 7¾′ |
| 310, *i*-3 | 18° 26′ | 26° 34′ | 540, $i\text{-}\frac{5}{4}$ | 38° 39½′ | 6° 20½′ |
| 940, $i\text{-}\frac{9}{4}$ | 23° 57¾′ | 21° 2¼′ | 650, $i\text{-}\frac{6}{5}$ | 39° 48¼′ | 5° 11¾′ |
| 210, *i*-2 | 26° 34′ | 18° 26′ | 870, $i\text{-}\frac{8}{7}$ | 41° 11¼′ | 3° 48¾′ |
| 740, $i\text{-}\frac{7}{4}$ | 29° 44¾′ | 15° 15¼′ | 14·13·0, $i\text{-}\frac{14}{13}$ | 42° 52¾′ | 2° 7¼′ |

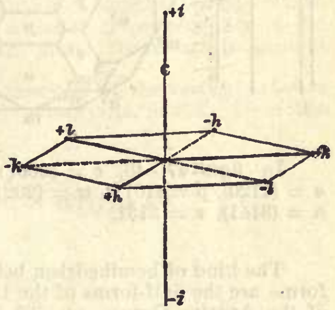
The vertical axis $\dot{c}$ can be obtained from the fundamental equations:

$$\tan (001 \wedge 101) = \dot{c} \quad \text{or} \quad \tan (001 \wedge 111) \, . \, \tfrac{1}{2}\sqrt{2} = \dot{c}.$$

### 3. HEXAGONAL SYSTEM.

The Hexagonal System includes (1) the HEXAGONAL SYSTEM proper, and (2) the RHOMBOHEDRAL DIVISION. In this work all the forms are referred to four axes, three equal axes (*a*) inclined at angles of 60° in a common horizontal plane and a fourth vertical axis ($\dot{c}$) at right angles to them and either longer or shorter.

42.



1. In the HEXAGONAL SYSTEM proper, there are 4 axial planes of symmetry, 3 equal planes intersecting at 60°, and a fourth unequal normal to them; also 3 auxiliary planes diagonal to the first set.

The general symbol for hexagonal forms is:

| 1. Weiss-Naumann | 2. Miller-Bravais |
|---|---|
| $pa : na : a : m\dot{c}$ | $hk\bar{l}i$ |

These symbols correspond to the symbols 1 and 2, already explained on p. xv. It is to be added that here $p = \frac{n}{n-1}$, in the first form, and $h + k - l = 0$ in the second. Special examples of these symbols are given in the list of forms below belonging to the hexagonal system. Note also that in the general symbol $hk\bar{l}i$, $h < k < l$; for example $(12\bar{3}1)$; this corresponds to the axes as shown in f. 42, and the spherical projection, f. 49. In stating the form (which includes 12 planes), it is customary to write it $kh\bar{l}i$, that is $(21\bar{3}1)$, and so in other cases.

The holohedral forms of this system are:

| | | | | | |
|---|---|---|---|---|---|
| 1. Basal plane | (0001) | *O* | 0*P* | *c* | |
| 2. Unit prism, or prism of first series | $(10\bar{1}0)$ | *I* | ∞*P* | *m* | |
| 3. Diagonal prism, or prism of second series | $(11\bar{2}0)$ | *i*-2 | ∞*P*2 | *a* | |
| 4. Dihexagonal prism | $(kh\bar{l}0)$ | *i-n* | ∞*Pn* | as $(21\bar{3}0, i\text{-}\frac{3}{2})$ | |
| 5. Unit pyramids, or first series (quartzoids) | $(h0\bar{h}i)$ | *m* | *mP* | as $(10\bar{1}1, 1)$ | or $(20\bar{2}1, 2)$ |
| 6. Diagonal pyramids, or second series | $(h{\cdot}h{\cdot}\overline{2h}{\cdot}i)$ | *m*-2 | *mP*2 | as $(11\bar{2}2, 1\text{-}2)$ | or $(11\bar{2}1, 2\text{-}2)$ |
| 7. Dihexagonal pyramids | $(kh\bar{l}i)$ | *m-n* | *mPn* | as $(21\bar{3}1, 3\text{-}\frac{3}{2})$ | |

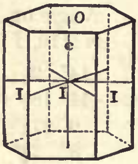
These forms are illustrated by figs. 43–47, also by the projections figs. 48, 49.

It is to be noted that the symbols of the planes of the forms *p* $(10\bar{1}1)$, *s* $(11\bar{2}1)$, taken in order (f. 48, 49), are:

| $p$ | $p'$ | $p''$ | $p'''$ | $p^{iv}$ | $p^{v}$ |
|---|---|---|---|---|---|
| $10\bar{1}1$ | $01\bar{1}1$ | $\bar{1}101$ | $\bar{1}011$ | $0\bar{1}11$ | $1\bar{1}01$ |
| $s$ | $s'$ | $s''$ | $s'''$ | $s^{iv}$ | $s^{v}$ |
| $11\bar{2}1$ | $\bar{1}2\bar{1}1$ | $\bar{2}111$ | $\bar{1}\bar{1}21$ | $1\bar{2}11$ | $2\bar{1}\bar{1}1$ |

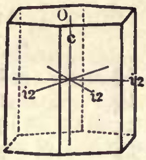
For the forms below, $p^{vi} = 10\bar{1}\bar{1}$, etc., $s^{vi} = 11\bar{2}\bar{1}$, etc. Also for $v\ (2\bar{1}\bar{3}1)$, $v' = 12\bar{3}1$, $v'' = \bar{1}3\bar{2}1$, $v^{xi} = 3\bar{1}\bar{2}1$, etc., cf. f. 49.

43.



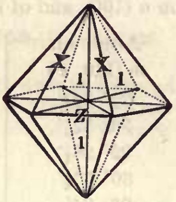
(10$\bar{1}$0)

44.



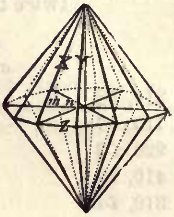
(11$\bar{2}$0)

45.



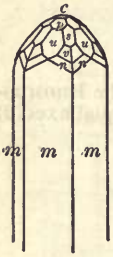
(10$\bar{1}$1)

46.

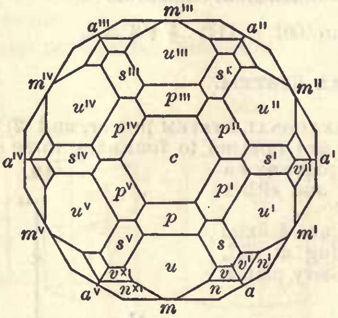


($kh\bar{l}i$)

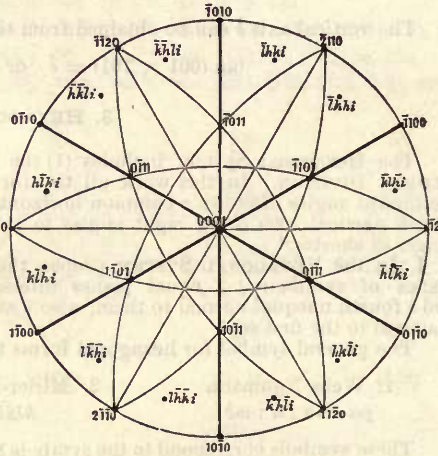
47.



48.



49.



In figs. 47, 48, $c = (0001)$, $m = (10\bar{1}0)$, $a = (11\bar{2}0)$, $p = (10\bar{1}1)$, $u = (20\bar{2}1)$, $s = (11\bar{2}1)$, $n = (31\bar{4}1)$, $v = 21\bar{3}1$.

The kind of hemihedrism belonging to this part of the system is the *pyramidal*, and the special forms are the half-forms of the 12-sided prism and pyramid; which are illustrated by the species of the Apatite Group, pp. 763–773. These half-forms are, respectively, a hexagonal prism, and hexagonal pyramid of the third series; cf. f. 4, p. 763, where the predominating form, $\mu\ (21\bar{3}1)$, is this pyramid.

2. The RHOMBOHEDRAL DIVISION includes forms with only three planes of symmetry intersecting at angles of 120° in the vertical axis. The forms peculiar to it may be regarded as half-forms of the corresponding hexagonal types. They are distinguished as plus and minus, as in similar cases before explained (p. xx). The forms peculiar to the rhombohedral system are the rhombohedron and scalenohedron, figs. 50–53, also f. 54 and the many other figures under calcite, pp. 263, 264, tourmaline, pp. 551, 552, etc.

The symbols for the several planes of the plus unit rhombohedron (f. 50, 54), always denoted by the letter $r$, are:

$$r = 10\bar{1}1 \quad r' = \bar{1}101 \quad r'' = 0\bar{1}11 \quad r''' = 01\bar{1}\bar{1} \quad r^{iv} = \bar{1}01\bar{1} \quad r^{v} = 1\bar{1}0\bar{1}$$

For the scalenohedron in general, which is regarded as a half-form on the same system of the dihexagonal pyramid, Naumann modified his symbols by referring the forms to the rhombohedron having the same lateral edges. His symbols read:

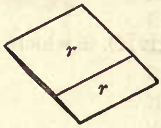
$mRn$, in this book written $m^n$,

where the $m$ and $n$ are connected with the corresponding $m_0$ and $n_0$ of the dihexagonal pyramid by the relations:

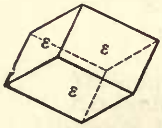
$$m = \frac{m_0(2 - n_0)}{n_0}, \quad n = \frac{n_0}{2 - n_0}, \quad \text{or} \quad m_0 = mn, \quad n_0 = \frac{2n}{n+1}.$$

Thus $\frac{1}{2}(3P\frac{3}{2})$ or $\frac{1}{2}(3\text{-}\frac{3}{2})$ is equivalent to $R^3$ or $1^3$.

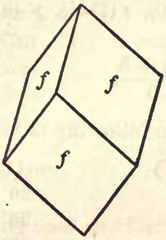
**50.**



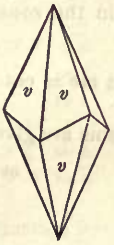
**51.**



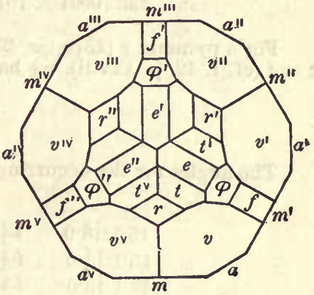
**52.**



**53.**



**54.**



$r = (10\bar{1}1, +R)$, $\epsilon = (01\bar{1}1, -R)$, $(f = 20\bar{2}1, +2R)$, $v = (31\bar{2}1, 1^3)$, also $m = (10\bar{1}0, I)$,
$a = (11\bar{2}0, i\text{-}2)$, $e = (01\bar{1}2, -\frac{1}{2}R)$, $\phi = (05\bar{5}4, -\frac{5}{4}R)$, $t = (21\bar{3}4, \frac{1}{4}^3)$

The hemihedral forms of the Rhombohedral Division, which are *tetartohedral* to the Hexagonal Division, are:

A. Rhombohedral. B. Trapezohedral.

The distinctive form of the rhombohedral-tetartohedral class is the hemi-scalenohedron, or rhombohedron of the third series, illustrated by figs. 4, 5, 9, under phenacite, p. 462. Cf. also figs. under dioptase, p. 464, ilmenite, p. 218, dolomite, p. 272.

The distinctive form of the *trapezohedral* class are the quadrilateral trapezohedron and the unsymmetrical trigonal prism, illustrated by quartz (pp. 184, 185) and cinnabar, p. 66. These forms may be either right- or left-handed, as shown in quartz, where their connection with the phenomena of circular polarization is explained. The plus and minus forms are in general designated by different letters.

There are also *hemimorphic* forms, in which the opposite extremities of the vertical axis are dissimilarly modified, as shown in tourmaline, pp. 551, 552, and pyrargyrite, p. 133. Here the unit prism becomes a trigonal form.

The important mathematical relations in this system are

$$\dot{c} = \tan(0001 \wedge 11\bar{2}2), \qquad \dot{c} = \tan(0001 \wedge 10\bar{1}1)\,.\,\tfrac{1}{2}\sqrt{3}.$$

Also for a hexagonal pyramid

$$\tan\tfrac{1}{2}(10\bar{1}1 \wedge 01\bar{1}1) = \sin\xi\sqrt{\tfrac{1}{3}}, \quad \text{where } \tan\xi = \dot{c},$$

and in general

$$\tan\tfrac{1}{2}(h0\bar{h}l \wedge 0h\bar{h}l) = \sin\xi_{,}\sqrt{\tfrac{1}{3}}, \quad \text{where } \tan\xi_{,} = \frac{h}{l}\dot{c}.$$

For a pyramid of the second series

$$2\sin\tfrac{1}{2}(11\bar{2}2 \wedge \bar{1}2\bar{1}2) = \sin\xi \quad \text{and} \quad \tan\xi = \dot{c}.$$

For a dihexagonal prism, $kh\bar{l}0$ (as, $21\bar{3}0$):

$$\cot(10\bar{1}0 \wedge kh\bar{l}0) = \frac{2k+h}{h}\sqrt{\frac{1}{3}};$$

$$\cot(11\bar{2}0 \wedge kh\bar{l}0) = \frac{k+h}{k-h}\sqrt{3}.$$

The sum of the above angles is equal to 30°.

For a rhombohedron

$$\sin \tfrac{1}{2}(10\bar{1}1 \wedge \bar{1}101) = \sin \alpha \sqrt{\tfrac{3}{4}}, \quad \text{where } \alpha = 0001 \wedge 10\bar{1}1\,;$$

in general

$$\sin \tfrac{1}{2}(h0\bar{h}l \wedge \bar{h}h0l) = \sin \alpha_{,} \sqrt{\tfrac{3}{4}}, \quad \text{where } \alpha_{,} = 0001 \wedge h0\bar{h}l.$$

In the vertical zone of pyramids, rhombohedrons, etc., the tangent principle holds

$$\frac{\tan\,(0001 \wedge h0\bar{h}l)}{\tan\,(0001 \wedge 10\bar{1}1)} = \frac{h}{l}\,; \quad \text{also} \quad \frac{\tan\,(0001 \wedge 11\bar{2}1)}{\tan\,(0001 \wedge 11\bar{2}2)} = 2, \quad \text{etc.}$$

For a pyramid *v* ($kh\bar{l}i$) (as, $21\bar{3}1$) in the zone *m* ($10\bar{1}0$), *s* ($11\bar{2}1$), *p′* ($01\bar{1}1$), *o′* ($\bar{1}2\bar{1}2$), in which $k = i$ (cf. f. 49, p. xxviii), we have:

$$\cot mv = \cot mp' \,.\, \frac{2k+h}{h}.$$

The angles for the occurring prisms are given by the following table:

| | | *m* ($10\bar{1}0$, *I*) | *a* ($11\bar{2}0$, *i*-2) |
|---|---|---|---|
| $15{\cdot}1{\cdot}\bar{16}{\cdot}0$ | *i*-$\frac{16}{15}$ | 3° 12′ | 26° 48′ |
| $13{\cdot}1{\cdot}\bar{14}{\cdot}0$ | *i*-$\frac{14}{13}$ | 3° 40¼′ | 26° 19¾′ |
| $12{\cdot}1{\cdot}\bar{13}{\cdot}0$ | *i*-$\frac{13}{12}$ | 3° 57¾′ | 26° 2¼′ |
| $10{\cdot}1{\cdot}\bar{11}{\cdot}0$ | *i*-$\frac{11}{10}$ | 4° 43′ | 25° 17′ |
| $71\bar{8}0$ | *i*-$\frac{8}{7}$ | 6° 35¼′ | 23° 24¾′ |
| $51\bar{6}0$ | *i*-$\frac{6}{5}$ | 8° 57′ | 21° 3′ |
| $41\bar{5}0$ | *i*-$\frac{5}{4}$ | 10° 53½′ | 19° 6½′ |
| $31\bar{4}0$ | *i*-$\frac{4}{3}$ | 13° 54′ | 16° 6′ |
| $52\bar{7}0$ | *i*-$\frac{7}{5}$ | 16° 6′ | 13° 54′ |
| $21\bar{3}0$ | *i*-$\frac{3}{2}$ | 19° 6½′ | 10° 53½′ |
| $9{\cdot}5{\cdot}\bar{14}{\cdot}0$ | *i*-$\frac{14}{9}$ | 20° 38′ | 9° 22′ |
| $8{\cdot}5{\cdot}\bar{13}{\cdot}0$ | *i*-$\frac{13}{8}$ | 22° 24⅞′ | 7° 35⅛′ |
| $32\bar{5}0$ | *i*-$\frac{5}{3}$ | 23° 24¾′ | 6° 35¼′ |
| $54\bar{9}0$ | *i*-$\frac{9}{5}$ | 26° 19¾′ | 3° 40¼′ |

## THE RHOMBOHEDRAL DIVISION OF MILLER.

The following projection (fig. 55) is added in order to show the relation of the forms in the Hexagonal and Rhombohedral Systems as referred by Miller to three equal oblique axes parallel to the faces of the fundamental rhombohedron. The forms are as follows

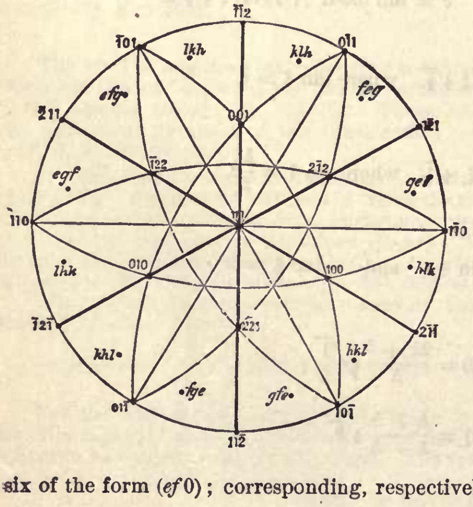
The planes having the indices 100, 001, 010 are those of the (plus) fundamental rhombohedron, while the plane 111 is the base. The planes 221, 121, 122 are those of the minus fundamental rhombohedron; with the planes 100, 010, 001 they form the unit hexagonal pyramid.

The hexagonal unit prism, $I = (10\bar{1}0)$, has the symbols: $11\bar{2}$, $2\bar{1}\bar{1}$, $1\bar{2}1$, $\bar{1}\bar{1}2$, $\bar{2}11$, $\bar{1}2\bar{1}$. The second, or diagonal hexagonal prism, $i\text{-}2 = (11\bar{2}0)$, has the symbols: $10\bar{1}$, $1\bar{1}0$, $0\bar{1}1$, $\bar{1}01$, $\bar{1}10$, $01\bar{1}$

The dihexagonal pyramid embraces, like the simple hexagonal pyramid, two forms (*hkl*) and (*efg*); the symbol (*hkl*) hence belongs to the plus scalenohedron, and (*efg*) to the minus. In this as in other cases it is true that $e = -h + 2k + 2l$, $f = 2h - k + 2l$, $g = 2h + 2k - l$.

The dihexagonal prism includes the six planes of the form (*hk*0), and the remaining six of the form (*ef*0); corresponding, respectively, to the pyramids (*hkl*) and (*efg*).

55.



### 4. ORTHORHOMBIC SYSTEM.

In the Orthorhombic System, there are three unequal axes at right angles to each other. These axes are the brachydiagonal $\breve{a}$, macrodiagonal $\bar{b}$, and vertical $\dot{c}$; in stating the axial ratio, $b$ is always made equal to unity. There are three planes of symmetry, which intersect in these axes, but which are all different. The types of forms in this system are:

| | | | | | |
|---|---|---|---|---|---|
| Macropinacoid | (100) | | $i$-$\bar{\imath}$ | $\infty P\bar{\infty}$ | $a$ |
| Brachypinacoid | (010) | | $i$-$\breve{\imath}$ | $\infty P\breve{\infty}$ | $b$ |
| Basal plane | (001) | | $O$ | $0P$ | $c$ |
| Unit prism | (110) | | $I$ | $mP$ | $m$ |
| Macroprism | ($hk0$) | $h > k$ | $i$-$\bar{n}$ | $\infty P\bar{n}$ | as (210, $i$-$\bar{2}$) |
| Brachyprism | ($kh0$) | $h > k$ | $i$-$\breve{n}$ | $\infty P\breve{n}$ | as (120, $i$-$\breve{2}$) |
| Macrodomes | ($h0l$) | | $m$-$\bar{\imath}$ | $mP\bar{\infty}$ | as (201, 2-$\bar{\imath}$) |
| Brachydomes | ($0kl$) | | $m$-$\breve{\imath}$ | $mP\breve{\infty}$ | as (021, 2-$\breve{\imath}$) |
| Unit pyramids | (111) | | 1 | $m$ | as (111, 1) |
| Macropyramids | ($hkl$) | $h > k$ | $m$-$\bar{n}$ | $mP\bar{n}$ | as (211, 2-$\bar{2}$) |
| Brachypyramids | ($khl$) | $h > k$ | $m$-$\breve{n}$ | $mP\breve{n}$ | as (121, 2-$\breve{2}$) |

These forms hardly need any further explanation beyond what has been given on pp. xv, xvi.

Hemihedral forms in this system are rare; hemimorphic forms are less so, but not very common, cf. calamine, p. 547, struvite, p. 806.

The axial ratio can be calculated from the simple relations

$$\breve{a} = \tan\,(100 \wedge 110),$$

$$\dot{c} = \tan\,(001 \wedge 011),$$

$$\frac{c}{a} = \tan\,(001 \wedge 101).$$

From the measured angles these elemental angles can be calculated, and *vice versa*, by the solution of spherical triangles on the sphere of projection with the aid of the tangent principle.

### 5. MONOCLINIC SYSTEM.

In the Monoclinic System there are three unequal axes, of which one lateral axis, $\grave{a}$, is inclined to the vertical axis, $\dot{c}$, while the angles between $\dot{c}$ and $\bar{b}$, and $\bar{b}$ and $\grave{a}$ are right angles. There is one plane of symmetry, the plane of the axes $\grave{a}$, $\dot{c}$. In stating the axial ratio, $b$ is always taken as the unit, and, in the majority of cases, $\grave{a}$, the clino-axis, is less than $\bar{b}$, the ortho-axis; this is not necessarily the case, however, hence the long mark used in the symbols is conventional only. The types of forms and the special terms employed are shown by the following list. The occurring types of forms are as follows:

| | | | | |
|---|---|---|---|---|
| Orthopinacoid | (100) | $i$-$\bar{\imath}$ | $\infty P\bar{\infty}$ | $a$ |
| Clinopinacoid | (010) | $i$-$\grave{\imath}$ | $\infty P\grave{\infty}$ | $b$ |
| Basal plane | (001) | $O$ | $0P$ | $c$ |
| Unit prism | (110) | $I$ | $\infty P$ | $m$ |
| Ortho-prism | ($hk0$) | $i$-$\bar{n}$ | $\infty P\bar{n}$ | as (210, $i$-$\bar{2}$) |
| Clino-prism | ($kh0$) | $i$-$\grave{n}$ | $\infty P\grave{n}$ | as (120, $i$-$\grave{2}$) |
| Orthodomes | $h0l$<br>$\bar{h}0l$ | $-\,m$-$\bar{\imath}$<br>$m$-$\bar{\imath}$ | $-\,mP\bar{\infty}$<br>$mP\bar{\infty}$ | as (101, $-$ 1-$\bar{\imath}$)<br>as ($\bar{1}$01, 1-$\bar{\imath}$) |
| Clinodomes | $0kl$ | $m$-$\grave{\imath}$ | $-\,mP\grave{\infty}$ | as (011, 1-$\grave{\imath}$) |
| Unit pyramids | $hhl$<br>$\bar{h}hl$ | $-\ m$<br>$m$ | $-\ mP$<br>$mP$ | as (111, $-$ 1)<br>as ($\bar{1}$11, 1) |
| Ortho-pyramids | $hkl$<br>$\bar{h}kl$ | $-\,m$-$\bar{n}$<br>$m$-$\bar{n}$ | $-\ mP\bar{n}$<br>$mP\bar{n}$ | as (211, $-$ 2-2)<br>as ($\bar{2}$11, 2-2) |
| Clino-pyramids | $khl$<br>$\bar{k}hl$ | $-\,m$-$\grave{n}$<br>$m$-$\grave{n}$ | $-\ mP\grave{n}$<br>$mPn$ | as (121, $-$ 2-2)<br>($\bar{1}$21, 2-2) |

Some of these forms are illustrated by the figures of gypsum with the spherical projection, given on p. xxxvi; also by the monoclinic species through the body of the work.

The relations connecting axial and angular elements are as follows:

$$\grave{a} = \frac{\tan (100 \wedge 110)}{\sin \beta} \quad \text{or} \quad \tan (100 \wedge 110) = \grave{a} \,.\, \sin \beta ; \qquad (1.)$$

$$\dot{c} = \frac{\tan (001 \wedge 011)}{\sin \beta} \quad \text{or} \quad \tan (001 \wedge 011) = \dot{c} \,.\, \sin \beta ; \qquad (2.)$$

$$\dot{c} = \frac{\grave{a} \,.\, \tan (001 \wedge 101)}{\sin \beta - \cos \beta \,.\, \tan (001 \wedge 101)} \quad \text{or} \quad \tan (001 \wedge 101) = \frac{\dot{c} \,.\, \sin \beta}{\grave{a} + \dot{c} \,.\, \cos \beta}, \qquad (3a.)$$

or

$$\dot{c} = \frac{\grave{a} \,.\, \tan (001 \wedge \bar{1}01)}{\sin \beta + \cos \beta \,.\, \tan (001 \wedge \bar{1}01)} \quad \text{or} \quad \tan (001 \wedge \bar{1}01) = \frac{\dot{c} \sin \beta}{\grave{a} - \dot{c} \,.\, \cos \beta}. \qquad (3b.)$$

These relations may be made more general by writing in the several cases—

in (1) $hk0$ for 110 and $\frac{k}{h}\grave{a}$ for $\grave{a}$;

(2) $0kl$ for 011 and $\frac{k}{l}\dot{c}$ for $\dot{c}$;

(3) $h0l$ for 100 and $\frac{h}{l}\dot{c}$ for $\dot{c}$.

Also

$$\frac{\dot{c}}{a} = \frac{\sin (001 \wedge 101)}{\sin (100 \wedge 101)} = \frac{\sin (001 \wedge \bar{1}01)}{\sin (100 \wedge \bar{1}01)},$$

and more generally

$$\frac{h}{k} \,.\, \frac{\dot{c}}{a} = \frac{\sin (001 \wedge h0l)}{\sin (100 \wedge h0l)} = \frac{\sin (001 \wedge \bar{h}0l)}{\sin (100 \wedge \bar{h}0l)}.$$

Note also that

$$\tan \phi = \grave{a} \quad \text{and} \quad \tan \zeta = \dot{c} ;$$

where $\phi$ is the angle (f. 63, p. xxxvi) between the zone-circles (001, 100) and (001, 110); also $\zeta$ the angle between (100, 001) and (100, 011).

## VI. TRICLINIC SYSTEM.

In the Triclinic System there are three unequal axes and their intersections are all oblique; there is no plane of symmetry, hence the system is often called the *Asymmetric* system. Only two planes belong to any given form, hence the prisms are hemi-prisms, the pyramids tetarto-pyramids, etc. The axes are designated $a$, $b$, $\dot{c}$, in which $a$ is usually the brachydiagonal axis (then written $\breve{a}$) and $b$ the macrodiagonal ($\bar{b}$); in some cases, however, $a$ is the longer and $b$ the shorter lateral axis. The axial angles are:

$\alpha$ between the axes $b$ and $\dot{c}$.
$\beta$ " " " $a$ and $\dot{c}$.
$\gamma$ " " " $a$ and $b$.

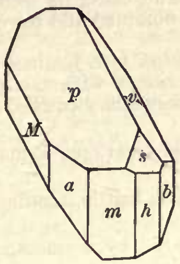
The symbols of Naumann are hence analogous to those of the orthorhombic system, but the different planes are distinguished by accents; thus:

| 111 | $\bar{1}11$ | $\bar{1}\bar{1}1$ | $1\bar{1}1$ |
|---|---|---|---|
| 1' | ,1 | 1, | '1 |

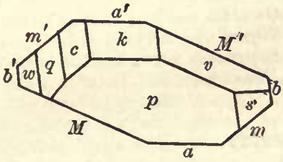
Also 110 = *I*, $1\bar{1}0$ = '*I*, 101 = '1-ī', $\bar{1}01$ = ,1-ī,, 011 = 1-ĭ', $0\bar{1}1$ = '1-ĭ, etc.

For illustrations of these cases, cf. figs. 56–58 of chalcanthite, also many other triclinic species in the body of the work.

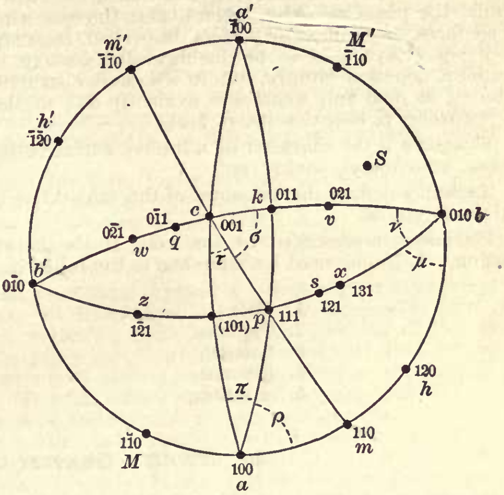
56.



57.



58.



In the figs., *a* = (100, *i-ĭ*), *b* = (010, *i-ĭ*), *c* = (001, *O*), *m* = (110, *I'*), *h* (120, *i-2'*), *M* (1$\bar{1}$0, *'I*); *k* (011, 1-*ĭ'*), *v* (021, 2-*ĭ'*), *q* (0$\bar{1}$1, '1-*ĭ*), *w* (0$\bar{2}$1, '2-*ĭ*), *p* (111, 1'), *s* (121, 2-$\breve{2}$'), *z* (1$\bar{2}$1, '2-$\breve{2}$).

In the spherical projection, the spherical angles of the triangle 100, 010, 001 are the supplements of the axial angles, viz.: the angle at 100 (A) = 180 – $\alpha$, at 010 (B) = 180° – $\beta$, at 001 (C) = 180° – $\gamma$.

These angles A, B, C can be calculated from the angles between the planes 100 ∧ 001, 100 ∧ 010, 001 ∧ 010, in the spherical triangle named and *vice versa*. Furthermore, cf, f. 58.

$$\frac{\sin\,\tau}{\sin\,\sigma} = \frac{\sin\,\tau'}{\sin\,\sigma'} = \frac{a}{b},$$

$$\frac{\sin\,\nu}{\sin\,\mu} = \frac{\sin\,\nu'}{\sin\,\mu'} = \frac{\dot{c}}{a},$$

$$\frac{\sin\,\pi}{\sin\,\rho} = \frac{\sin\,\pi'}{\sin\,\rho'} = \frac{\dot{c}}{b}.$$

Here A = $\pi + \rho$, B = $\nu + \mu$, C = $\tau + \sigma$; 180° – A = $\pi' + \rho'$ (in adjacent quadrant), etc.

These relations become general for any plane *hkl*, where $\tau_x$ $\sigma_x$ are the corresponding angles and we have

$$\frac{\sin\,\tau_x}{\sin\,\sigma_x} = \frac{a}{\frac{h}{k}b}, \quad \text{etc.}$$

For other mathematical relations, reference must be made to works on Crystallography.

## II. PHYSICAL MINERALOGY.

In general the physical characters of crystallized minerals conform to the symmetry of the system to which the crystals belong. That is, the cleavage must be alike in all directions which are crystallographically similar in a given species, etc.

The following are brief explanations in regard to the successive physical characters

### A. CHARACTERS DEPENDING UPON COHESION.

**Cleavage** is the natural fracture of a crystallized mineral yielding more or less smooth surfaces; it is due to minimum cohesion. The cleavage is characterized, first according to direction, as cubic, octahedral, dodecahedral, also basal, prismatic, etc.; in general $\parallel x$, or parallel the plane $x$. Also, second, as to the ease with which it is obtained and the character of the surfaces, as eminent or perfect, imperfect, interrupted, etc.

From cleavage is to be distinguished *parting*, or the separation into laminæ, due not to minimum cohesion simply, but to a lamellar structure often connected with the presence of twinning laminæ and sometimes evidently due to the action of secondary causes, as pressure (cf. pyroxene, p. 354, titanite, p. 713).

**Fracture** is the character of a broken surface other than that of cleavage; it may be even, uneven, conchoidal, hackly, etc.

**Tenacity** defines the character of the mineral as to whether it is brittle, sectile, malleable, flexible, or elastic.

**Hardness**, represented by the letter H., is the resistance offered by a smooth surface to abrasion. It is measured by reference to the following scale of Mohs:

1. *Talc.*
2. *Gypsum.*
3. *Calcite.*
4. *Fluorite.*
5. *Apatite.*
6. *Feldspar.*
7. *Quartz.*
8. *Topaz.*
9. *Sapphire.*
10. *Diamond.*

### B. SPECIFIC GRAVITY OR DENSITY.

**Specific Gravity**, represented by the letter G., is the density compared with that of water, strictly speaking, with water at 4° C. (39·2° F.). Practically a determination of specific gravity need not take into account the temperature unless a very high degree of accuracy is called for, e.g., when it is to be accurate to a unit in the third decimal place. Inasmuch as the material available is seldom faultless, the unavoidable error of experiment is usually greater than the limit of accuracy noted, and hence temperature may be neglected.

The specific gravity of a mineral varies with variation in composition, sometimes widely (cf the garnets, pyroxene, etc.). When the composition is constant, however, the specific gravity carefully taken on material free from mechanical admixture is nearly constant. Hence the wide variation often given is usually due to faulty observation or to poor material. In the descriptions of species which follow, a large number of determinations are quoted, particularly with the tables of analyses.

### C. CHARACTERS DEPENDING UPON LIGHT.

(*a*) **Luster.**—A. The KINDS OF LUSTER are:
1. *Metallic:* the luster of metals; if imperfect it is called *sub-metallic.*
2. *Adamantine:* the luster of the diamond.
3. *Vitreous:* the luster of broken glass.
4. *Resinous:* luster of the yellow resins.
5. *Greasy:* as that of elæolite.
6. *Pearly:* like pearl.
7. *Silky:* like silk; it is the result of a fibrous structure.

B. The DEGREES OF INTENSITY are:
1. *Splendent.*
2. *Shining.*
3. *Glistening.*
4. *Glimmering.*

[When there is a total absence of luster, a mineral is characterized as *dull.*]

(*b*) **Color.**—Usually the color by reflected light is given, sometimes also by transmitted light. The special terms employed need no explanation.

The *streak* is the color of the fine powder when scratched by the knife or, better, rubbed upon a surface of unglazed porcelain. The streak is of most importance in the case of minerals containing the heavy metals. It is usually omitted in the description of species when it is uncolored.

*Pleochroism,* or the difference in color shown by many crystals for light transmitted in different directions through them, is a special case of color-absorption, but is more conveniently treated as a special optical property, see beyond, p. xxxvii.

(*c*) **Diaphaneity,** or degree of transparency.—Minerals may be *transparent, sub-transparent* or *semi-transparent, translucent, subtranslucent, opaque.*

(*d*) **Special Optical Properties.**—ISOTROPIC CRYSTALS.—Transparent isometric crystals and amorphous substances (e.g., glass) are *isotropic* with respect to light. They have a single index of refraction, represented by the letter $n$, and further defined according to the color, as $n_y$ or $n_r$, etc.

Crystals of all the other systems are *anisotropic*.

*Optical Anomalies.*—The term optical anomalies is applied to the optical phenomena exhibited in polarized light, particularly by many crystals of the isometric system, which are so far abnormal or anomalous in that they do not conform to the external crystallographic form. Here belongs the double refraction of boracite, of most garnet, also analcite, etc.; further, the biaxial character of much beryl, apophyllite, etc. This is a subject to which much attention has been given of late years, particularly since the publication of the classical paper by Mallard (1876). Details in regard to it, with references to the literature, will be found under the species named and many others.

In this connection it may be noted that the term *pseudo-symmetry* (also pseudo-isometric, etc.) is used, first of crystals belonging to one system but approximating in angle closely to one of higher symmetry; thus biotite is said to be pseudo-rhombohedral. Also, second, to crystals which gain an apparent symmetry of higher grade than that actually belonging to them by twinning; thus aragonite is said to be pseudo-hexagonal by twinning.

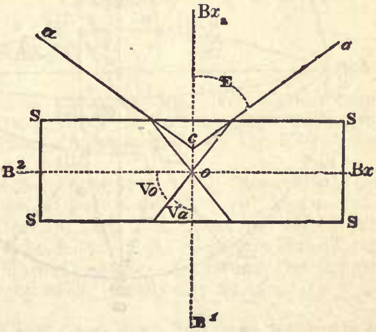
UNIAXIAL CRYSTALS.—Tetragonal and hexagonal crystals are *uniaxial*, or have one axis of optical symmetry in which direction a ray of transmitted light suffers no double refraction. This optic axis coincides with the vertical crystallographic axis in the position of the crystals ordinarily taken and here followed. Further, they have two indices of refraction, that corresponding to the ordinary ray (represented by $\omega$) whose vibrations are transverse to the vertical axis ($\perp \dot{c}$), and that of the extraordinary ray ($\epsilon$) with vibrations parallel to this axis ($\parallel \dot{c}$). The character of the crystal is optically positive (+) or negative (−) according as $\omega < \epsilon$, or $\omega > \epsilon$. The double refraction is strong or weak according as to whether the difference $\omega - \epsilon$ (or $\epsilon - \omega$) is relatively large or small. For example, it is strong in calcite, where $\omega - \epsilon = 0{\cdot}172$, but very weak in apophyllite, where $\epsilon - \omega = 0{\cdot}002$. Crystals of these systems may be *dichroic*, according to the kind and degree of absorption in the two axial directions $\perp \dot{c}$ and $\parallel \dot{c}$, cf. tourmaline, p. 553.

Crystals belonging to the trapezohedral (tetartohedral) section of the rhombohedral division of the hexagonal system show circular polarization, and are right- or left-handed according as they rotate the plane of polarization of a ray of light passing from the observer through the crystal to his right or left. The amount of rotation for a section of unit thickness (e.g., 1 mm.) varies with the wave-length; cf. quartz, p. 186.

BIAXIAL CRYSTALS.—Crystals of the orthorhombic, monoclinic, and triclinic systems are *biaxial* and have three axes of elasticity, or three directions at right angles to each other, in which the elasticity of the light ether has its minimum $\mathfrak{c}$, maximum $\mathfrak{a}$, and mean value $\mathfrak{b}$. They have also three indices of refraction for a given wave-length, $\alpha, \beta, \gamma$, for rays whose vibrations are parallel to the axes $\mathfrak{a}$, $\mathfrak{b}$, $\mathfrak{c}$, respectively; here $\alpha < \beta < \gamma$.

The plane of the greatest and least axes of elasticity is the *optic axial plane* (usually contracted *Ax. pl.*), since it contains the optic axes or the two directions of no double refraction. The angles between the optic axes are bisected by the axes $\mathfrak{a}$ and $\mathfrak{c}$. The axis bisecting the acute angle is the *acute bisectrix*, $Bx_a$ or simply the bisectrix, the other is the *obtuse bisectrix*, $Bx_o$. The crystal is optically positive (+) or negative (−) according to whether $Bx_a$ is the axis of least elasticity ($\mathfrak{c}$) or greatest elasticity ($\mathfrak{a}$). The double refraction is strong or weak according as to whether the difference of the refractive indices $\gamma - \alpha$ is relatively large or small; for example it is strong in epidote with $\gamma - \alpha = 0{\cdot}055$; but weak in zoisite with $\gamma - \alpha = 0{\cdot}006$.

59.



The angle of the optic axes is designated (cf. f. 59) as follows:

2V = real or interior angle of the optic axes;
2E = apparent angle " " " " in air;
2H = " " " " " " measured in oil or some other medium of high refractive power.*

The distinction between the acute and obtuse axial angle is designated by $2V_a$, $2V_o$, etc., and the angles for the different colors, usually red, yellow, and green or blue, are written $2V_{a.r}$, $2V_{a.y}$, $2V_{a.gr}$, etc.

In *Orthorhombic* crystals the axes of elasticity coincide with the crystallographic axes, or axes of symmetry; accordingly the axial plane is parallel to one of the pinacoids ($\parallel a$, $\parallel b$, or $\parallel c$),

---

*It is often convenient to designate this angle by 2K when measured in a solution of mercuric iodide in potassium iodide (G. = 3·117, $n_y = 1{\cdot}7176$, Gdt.); also by 2G when measured in the glass of the Adams-Schneider polariscope.

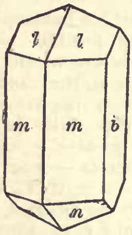
and the bisectrix is normal to one of these planes (Bx ⊥ $c$, etc.). Since, however, the refractive indices may vary for rays of different wave-length, the axial angle may be larger for red than for blue rays or vice versa, and this dispersion is characterized as $\rho > v$ or $\rho < v$.

In *Monoclinic* crystals one axis of elasticity coincides with the orthodiagonal axis, $\bar{b}$, and the others lie in the plane of symmetry (parallel to the pinacoid $b$ (010, *i-ĭ*) ) normal to it. Hence the axial plane may be ∥ $b$ or ⊥ $b$; if the latter, its position must be further defined according to the angle that it makes either with the normals to the planes $a$ or $c$, or more conveniently with the vertical axis, $\dot{c}$.

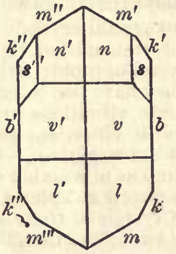
Three cases are possible:

1. Axial plane parallel to the plane of symmetry (Ax. pl. ∥ $b$); the position of the bisectrices is usually indicated by reference to the vertical axis, and the angle formed is called + or − according as the bisectrix ($Bx_a$) falls in front of or behind $\dot{c}$ (the middle point in the sphere of projection, f. 63), that is, is situated in the obtuse or acute axial angle.

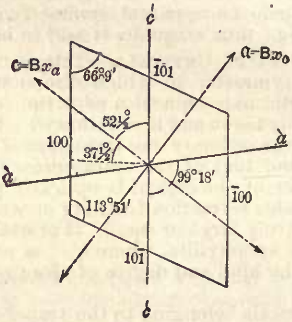
60.



61.

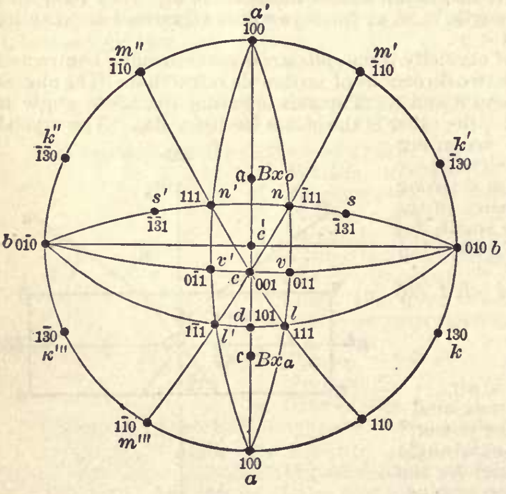


62.



For example, gypsum (f. 60–63) is optically positive, hence the axis of elasticity, 𝔠, is the acute bisectrix, $Bx_a$. Further (f. 62, 63), the position of $Bx_a$ is defined (Des Cloizeaux) by the angle, $Bx_a \wedge \dot{c} = +52\frac{1}{2}°$. But since the axial angle $\beta$ or $ac$ (001 ∧ 100) = 80° 42′, it is also true that the normal angles between 𝔠 or 𝔞 and the planes $c$, $a$ are as follows:

63.



$$\mathfrak{c}c = +43°\ 12',$$
$$\mathfrak{a}c = +37°\ 30',$$
and $$\mathfrak{c}a = -46°\ 48'$$

With varying positions of the axes 𝔞 and 𝔠 (the bisectrices) the axial planes for different colors may be more or less inclined to one another in the plane of symmetry, and this *dispersion of the bisectrices* is hence called *inclined dispersion.*

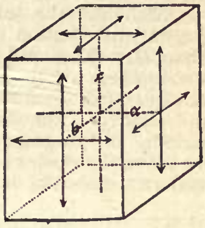
2. If the axial plane and the obtuse bisectrix are normal to the plane of symmetry (Ax. pl. and $Bx_o$ ⊥ $b$), then the position of the axial plane is further defined by that of the acute bisectrix in the plane of symmetry, which is written in the form just explained ($Bx_a \wedge \dot{c} = \pm$). The dispersion of the bisectrices possible in this case is called *horizontal*, in consequence of the relative position of the axial planes to each other.

3. If the axial plane and the acute bisectrix are normal to the plane of symmetry (Ax. pl. and $Bx_a$ ⊥ $b$) the position of the axial plane is further defined by that of the obtuse bisectrix ($Bx_o$) ± with reference to the vertical axis. The dispersion of the bisectrices for different colors which may be present in this case is called *crossed.*

In the *Triclinic System* there is no necessary relation between the assumed crystallographic axes and the axes of elasticity. Hence also the dispersion may be, for example, both horizontal and inclined. Cf. f. 58, p. xxxiii, of chalcanthite (see also p. 944), where $S$ represents approximately the position of $Bx_a$, or in other words is the pole or normal to the plane at right angles to the acute bisectrix.

**Pleochroism and Absorption.**—Biaxial crystals, having three axes of elasticity, may show different degrees or kinds of absorption in different directions, usually assumed as those of the axes of elasticity. The degree of absorption is designated as $\mathfrak{a} > \mathfrak{b} > \mathfrak{c}$, etc. Further, according to the kind of selective absorption, the crystal may be dichroic or trichroic (or better, in general, pleochroic), in which cases the colors corresponding to the vibrations parallel to the axes of elasticity are usually given (cf. f. 64). It has been shown, however, that the axes of absorption do not necessarily coincide with the axes of elasticity (cf. epidote, p. 518).

64.



The optical characters of mineral species are given very fully in the Mineralogy (vol. 1, 1862, and 2, part I, 1874) and in certain prominent memoirs of Des Cloizeaux (see Bibliography); the results of earlier investigations are also given by Grailich, Lang, Schrauf, and others; further, later by Rosenbusch (Mikr. Phys.), Lévy-Lacroix (Min. Roches), etc.

### D. CHARACTERS RELATING TO HEAT.

Here belong: the fusibility, defined, however, under the pyrognostic characters (p. xl); the thermal conductivity, and the position of the thermic axes (also the effect of heat in changing the crystallographic and optical constants); further, the specific heat.

These subjects are briefly treated under the different species, and references to many important memoirs are given. Recent determinations of the specific heat have been made by Joly (Proc. Roy. Soc., **41**, 250, 1887), also by Öberg, Öfv. Ak. Stockh., **42**, No. 8, 43, 1885.

### E. CHARACTERS RELATING TO MAGNETISM AND ELECTRICITY.

A few minerals are strongly magnetic and sometimes show polarity, e.g., magnetite, pyrrhotite, iron-platinum. Many species are diamagnetic, and the diamagnetic constant, also the magnetic rotatory power, have been determined in a few cases, e.g., calcite.

The electrical properties include (1) the power of becoming strongly electrified by friction, e.g., amber, p. 1002; (2) pyroelectricity, or the state of electric potential (+ and −) developed in crystallographically dissimilar parts of a crystal (non-conductor) by change of temperature, also by pressure (piezo-electricity), or by direct radiation (actino-electricity), cf. tourmaline, p. 553, calamine, p. 547, quartz, p. 186. Also (3) thermo-electricity, or the electromotive force established in some metallic minerals when they form an electric circuit with another conductor and one point of junction is changed in temperature, cf. pyrite, p. 85. Further, the electrical conductivity or resistance to the passage of an electrical current, and other points.

For the most part, these characters coming under the heads of Heat, Electricity, Magnetism are so far special that they are treated very briefly—if at all—in this work under the individual species; references are given, however, to many important papers. Further, the student is referred to the works on Physical Mineralogy by Groth, Mallard, Liebisch, already mentioned. Special investigations in pyroelectricity have been made by Hankel (Abh. Sächs. Ges. Wiss., also, Wied. Ann.) and by others. A recent paper on thermo-electricity is given by Bäckström, Öfv. Ak. Stockh., **45**, 553, 1888; also one on the production of electrical potential by the action of light by Elster and Geitel in Wied. Ann., **44**, 722, 1891.

## III. CHEMICAL MINERALOGY.

**Chemical Composition (Comp.) and General Scheme of Classification.**—The classification adopted in this work, as in the preceding edition, follows, first the chemical composition, and second crystallographic and other physical characters which indicate more or less clearly the relations of individual species.

The general outline of the chief chemical divisions is given on p. 1. As seen there, the elements are placed first; then compounds in which the acidic part is taken by sulphur and the allied elements, selenium, tellurium, also by arsenic, antimony, bismuth; these include in part simple Sulphides, Selenides, etc., and after them, the Sulpho-salts. Next come the Haloids, or compounds of the metals with chlorine, bromine, iodine, fluorine; after these follow the oxygen compounds; first the Oxides and then the various Oxygen-salts; finally the Salts of Organic Acids and Hydrocarbon compounds.

Among the Oxygen-salts, the Carbonates are placed first (thus deviating from the order in the last edition), and after them the Silicates and Titanates, which last are closely connected with the Niobates and Tantalates. Then follow the Phosphates, Arsenates, etc. After them are placed the Borates, and next the Uranates (the latter might properly be placed after the Tungstates); then come the large class of Sulphates with the allied Chromates and Tellurates, and finally the less closely related Tungstates and Molybdates.

In order to understand the relations of these chief classes, as still more their further subdivision, down finally to the many *isomorphous groups*—groups of species having analogous composition and closely similar form—the fundamental relations and grouping of the elements must be understood, especially as developed of recent years and shown in the so-called Periodic Law.

Although the subject can be only briefly touched upon, it will be useful to give here the general distribution of the elements into Groups and Series, as presented in the Principles of Chemistry (Engl. Ed., 1891) of D. Mendeléeff, to whom is due more than any one else the development of the Periodic Law. A few remarks are added on the grouping of the elements as illustrated by mineral compounds; artificial compounds show these relations still more fully and clearly. For the thorough explanation of this subject, more particularly as regards the periodic or progressive relation between the atomic weights and various properties of the elements, the reader is referred to the work above mentioned or to one of the many other excellent modern text-books of chemistry.

| Groups . . . . . | I | II | III | IV | V | VI | VII | VIII |
|---|---|---|---|---|---|---|---|---|
| Series 1 . . . . . | H | — | — | $RH_4$ | $RH_3$ | $RH_2$ | RH | Hydrogen Compounds |
| " 2 . . . . . | Li | Be | B | C | N | O | F | |
| " 3 . . . . . | Na | Mg | Al | Si | P | S | Cl | |
| " 4 . . . . . | K | Ca | Sc | Ti | V | Cr | Mn | Fe Co Ni Cu |
| " 5 . . . . . | (Cu) | Zn | Ga | Ge | As | Se | Br | |
| " 6 . . . . . | Rb | Sr | Y | Zr | Nb | Mo | — | Ru Rh Pd Ag |
| " 7 . . . . . | Ag | Cd | In | Sn | Sb | Te | I | |
| " 8 . . . . . | Cs | Ba | La | Ce | Di? | — | — | |
| " 9 . . . . . | — | — | — | — | — | — | — | |
| " 10 . . . . . | — | — | Yt | — | Ta | W | — | Os Ir Pt Au |
| " 11 . . . . . | Au | Hg | Tl | Pb | Bi | — | — | |
| " 12 . . . . . | — | — | — | Th | — | U | — | |
| | $R_2O$ | $R_2O_2$ | $R_2O_3$ | $R_2O_4$ | $R_2O_5$ | $R_2O_6$ | $R_2O_7$ | Higher Oxides |
| | | RO | | $RO_2$ | | $RO_3$ | | $RO_4$ |

The relations of some of the elements of the first group are exhibited by the isomorphism of NaCl, KCl, AgCl (p. 152); or again of $LiMnPO_4$ and $NaMnPO_4$, etc. (p. 756). In the second group, reference may be made to the isomorphism of the carbonates (p. 261) and sulphates (p. 894) of calcium, barium and strontium; while among the sulphides, ZnS, CdS, and HgS are doubly related (pp. 59, 66). In the third group, we find boron and aluminium often replacing one another among silicates. In the fourth group, the relations of silicon and titanium are shown in the many titano-silicates, while the compounds $TiO_2$, $SnO_2$, $PbO_2$ (and $MnO_2$), also $ZrSiO_4$ and $ThSiO_4$, have closely similar form (pp. 233, 234). In the fifth group, many compounds of arsenic, antimony, and bismuth are isomorphous among metallic compounds while the relations of phosphorus, vanadium, arsenic, also antimony, are shown among the phosphates, vanadates, arsenates, and antimonates; again note the mutual relations of the niobates and tantalates (p. 725),

In the sixth group, the strongly acidic elements, sulphur, selenium, tellurium, are all closely related, as seen in many sulphides, selenides, tellurides; further, the relations of sulphur and chromium, and similarly both of these to molybdenum and tungsten, are shown among many artificial sulphates, chromates, also molybdates and tungstates.

In the seventh group the relations of the halogens are too well understood to need special remark. In the eighth group, we have Fe, Co, Ni alloyed in meteoric iron, and their phosphates and sulphates (pp. 928, 929) are in several cases closely isomorphous; further the relation of the iron series to that of the platinum series is exhibited in the isomorphism of $FeS_2$, FeAsS, $FeAs_2$, $NiAs_2$, etc., with $PtAs_2$ and probably $RuS_2$ (p. 93).

**Formulas.**—The fact that the formula of a species is always given in two places, first in the tabular classification of each group, and, second, under the description of the species itself, affords an opportunity to vary the form in which it is stated. Thus malachite (pp. 293, 294), a basic cupric carbonate, has strictly the formula $Cu_2(OH)_2CO_3$, which indicates that the affinities of one atom of copper are satisfied by the double hydroxyl group 2(OH), and the other by the group $CO_3$. It is, however, often convenient to think of this as if it were made up of cupric carbonate and cupric hydrate and accordingly the formula (p. 295) is also written $CuCO_3.Cu(OH)_2$. To the latter is added the formula after the old dualistic system, $2CuO.CO_2.H_2O$, and in general the composition of most species is given in this form. It is interesting to note that the last method, generally discarded when the atomic theory was adopted, has ~~come~~ back again, since in the case of complex compounds it presents the composition most clearly before the mind. It is to be noted, however, that the period used in both the above cases (some authors employ a comma) is merely a conventional sign and does not indicate that the different molecular groups separated by it are regarded as present in the substance in that form. When it is intended to express this, a plus sign (+) is employed, as $NaCO_3 + 10H_2O$, or sodium carbonate with ten molecules of water of crystallization.

The formulas given are in general the simple empirical formulas, written, where possible in brief form, so as to suggest the actual nature of the compound. Thus $(CaF)Ca_4(PO_4)_3$ means a salt of orthophosphoric acid $3(H_3PO_4)$ in which the 9 hydrogen atoms are replaced by the 4 calcium atoms with also the univalent group CaF.

That the formula of a mineral does not necessarily express the structure of the molecule is too obvious to need explanation; not only is the atomic grouping often uncertain, but, as has been repeatedly remarked, the composition of the actual molecule, for example, of corundum is doubtless expressed by $nAl_2O_3$, where the factor $n$ is as yet undetermined. The first office of a mineralogical formula, however, is to present to the mind as clearly as possible the composition of the species, and if with that an indication can be given of the molecular structure, that is a decided gain, but complex structural or rational formulas are in a work like the present entirely out of place.

But not only is the actual molecular structure of mineral species in most cases doubtful, but even the simple empirical composition of many species, often common ones, is still unsettled. This is particularly true among the more complex silicates. Analysis has shown in many such cases that no single formula can express the composition, but that a varying basic or acidic character may belong to the same species. In such cases recourse is often had to the theory of isomorphous mixtures which has thrown so much light upon the Feldspar Group (p. 314 *et seq.*), but the extreme or end compounds assumed are often hypothetical, and the correctness of the views which have been proposed needs confirmation. Clarke has shown that the variation in composition within the limits of a single species may be often explained in such cases by regarding the different forms as derivatives of a normal salt in which various atoms or molecular groups may enter. The theory thus advanced, supported by the experimental data which the same author is accumulating, promises to bring useful results.

The *oxygen ratio*, in the case of the silicates, is the ratio of the oxygen atoms belonging to the different groups of basic metals and to the acidic silicon, as seen clearly if the formula is written in the dualistic form. Thus for garnet, whose formula is $Ca_3Al_2Si_3O_{12}$ or $3CaO.Al_2O_3.3SiO_2$, the oxygen ratio for $Ca : Al_2 : Si$ is $3 : 3 : 6 = 1 : 1 : 2$; that is, for bases to silicon 1 : 1. This ratio is the same as the quantivalent ratio, which for garnet, $\overset{II}{R}_3[\overset{VI}{R}_2]\overset{IV}{Si}_3O_{12}$, is:

$$3 \times II : VI : 3 \times IV = 6 : 6 : 12 = 1 : 1 : 2.$$

Although not strictly in accord with modern chemical principles, the oxygen ratio is often a useful way of expressing the general nature of a complex compound.

The following atomic weights have been accepted, and from them the theoretical composition of each species has been calculated:

| | Symbol. | At. Weight. |
|---|---|---|
| Aluminium | Al | 27 |
| Antimony (*Stibium*) | Sb | 120 |
| Arsenic | As | 74·9 |
| Barium | Ba | 137 |
| Beryllium | Be (or Gl) | 9·1 |
| Bismuth | Bi | 207·5 |
| Boron | B | 10·9 |
| Bromine | Br | 79·8 |
| Cadmium | Cd | 111·7 |
| Cæsium | Cs | 58·7 |
| Calcium | Ca | 39·9 |
| Carbon | C | 12 |
| Cerium | Ce | 141 |
| Chlorine | Cl | 35·4 |
| Chromium | Cr | 52·5 |
| Cobalt | Co | 58·7 |
| Columbium, see *Niobium* | | |
| Copper (*Cuprum*) | Cu | 63·2 |
| Didymium | Di | 142 |
| Erbium | Er | 166 |
| Fluorine | F | 19·1 |
| Gallium | Ga | 69·9 |
| Germanium | Ge | 73·3 |
| Glucinum, see *Beryllium* | | |
| Gold (*Aurum*) | Au | 196·7 |
| Hydrogen | H | 1 |
| Indium | In | 113·4 |
| Iodine | I | 126·5 |
| Iridium | Ir | 192·5 |
| Iron (*Ferrum*) | Fe | 55·9 |
| Lanthanum | La | 138 |
| Lead (*Plumbum*) | Pb | 206·4 |
| Lithium | Li | 7 |
| Magnesium | Mg | 24 |
| Manganese | Mn | 54·8 |
| Mercury (*Hydrargyrum*) | Hg | 199·8 |

| | Symbol. | At. Weight. | | Symbol. | At. Weight. |
|---|---|---|---|---|---|
| Molybdenum | Mo | 96 | Sodium (*Natrium*) | Na | 23 |
| Nickel | Ni | 58·6 | Strontium | Sr | 87·3 |
| Niobium | Nb | 93·7 | Sulphur | S | 32 |
| Nitrogen | N | 14 | Tantalum | Ta | 182 |
| Osmium | Os | 191 | Tellurium | Te | 125 |
| Oxygen | O | 16 | Thallium | Tl | 203·7 |
| Palladium | Pd | 106·2 | Thorium | Th | 232 |
| Phosphorus | P | 31 | Tin (*Stannum*) | Sn | 117·4 |
| Platinum | Pt | 194·3 | Titanium | Ti | 48 |
| Potassium (*Kalium*) | K | 39 | Tungsten (*Wolframium*) | W | 183·6 |
| Rhodium | Rh | 104·1 | Uranium | U | 240 |
| Rubidium | Rb | 85·2 | Vanadium | V | 51·1 |
| Ruthenium | Ru | 103·5 | Ytterbium | Yt | 172·6 |
| Scandium | Sc | 44 | Yttrium | Y | 89 |
| Selenium | Se | 78·9 | Zinc | Zn | 65·1 |
| Silicon | Si | 28 | Zirconium | Zr | 90·4 |
| Silver (*Argentum*) | Ag | 107·7 | | | |

For a minute discussion of the many analyses and other points involved in Chemical Mineralogy, reference is made to the Mineralchemie of Rammelsberg, also to the works of Doelter and Roth, whose titles are given in the Bibliography following. On the views of Tschermak in case of complex species and groups of species, see the Feldspars (p. 325), Scapolites (p. 466), Micas (p. 612), Chlorites (p. 643); for references to the work of Clarke and his memoirs, see pp. 311, 612, 648 *et seq.* Hunt's recent volumes, noted in the Bibliography, contain his views on the subject of mineral classification, especially as based upon what he calls the coefficient of condensation.

**Pyrognostics (Pyr.).**—The Blowpipe Characters, or *pyrognostics*, include, first, the fusibility, in which the following scale (von Kobell, cf. p. 1034) is employed:

1. Stibnite. 2, Natrolite. 3, Almandite garnet. 4, Green actinolite. 5, Orthoclase. 6, Bronzite.

Further, they include the behavior of the mineral as to flame coloration, on charcoal, in the open and closed tubes (tube closed at one end), etc. Here B.B. means before the blowpipe; O.F. is the oxidizing flame or that which tends to give oxygen to the mineral being heated; R.F. is the reducing flame which tends to rob it of oxygen. It is to be noted that the use of the blowpipe is for the most part an easy method of qualitative chemical analysis.

With the proper blowpipe characters are given also the degree of solubility, behavior with acids, etc. On blowpipe analysis, see further Brush, Determ. Min. (1875), also the excellent works by Plattner, Cornwall, and others (Bibliography).

**Alteration (Alt.).**—Under this head is given brief mention of the changes to which the prominent species are liable, and frequently analyses of the products of alteration. With this is often added a statement as to the species from whose alteration it may result and after which it may accordingly occur as a pseudomorph.

For fuller information on this head the works of Blum and Roth should be consulted.

**Artificial Compounds (Art.).**—This head states some of the results as to the formation of chemical compounds occurring as minerals either in the laboratory or by the furnace. This subject which has been largely developed of recent years, especially by the French chemists, is fully discussed in the works of Fouqué-Lévy, Bourgeois, and Meunier; also earlier, Fuchs and others (see Bibliography).

## IV. NOMENCLATURE.*

1. The termination *ites* or *itis* (the original of *ite*) was used, according to system, among the Greeks, and from them among the Romans, in the names of stones, it being one of the regular Greek suffixes. It was added (as *ite* in these recent times) to the word signifying a *quality*, *constituent*, *use*, or *locality* of the stone.

Some of the examples are : *Hæmatites*, from the red color of the powder; *Chloritis*, from the green color; *Steatites*, from the greasy feel; *Dendritis*, from a resemblance to a tree or branch: *Alabastritis*, for the stone out of which a vase called an *alabastron* was made; *Basanites*, from the word for touchstone; *Siderites*, from the word for iron; *Argyritis*, from the Greek for silver; *Syenitis*, from the *locality*, Syene in Egypt; *Memphitis*, for a marble from Memphis in Egypt.

2. The only modern kind of name not in vogue in Pliny's time is that after persons.

Werner appears to have been the first to introduce personal names into mineralogy. The

---

* Reproduced almost entire, and without much change, from the 5th Edition; the principles stated are followed (but not quite rigidly) in this edition. The fact that Prehnite probably antedated Torbernite (cf. 5th Ed., p. xxix) has been pointed out to the author of the present edition by Prof. A. H. Chester of Rutgers College (Feb. 1892).

earliest example was probably *Prehnite* (before called chrysolite), named after Col. Prehn; this name, according to Werner's statement (Bergm. J., **1**, 107, 1890), was given in 1783. About the same time he named *Torbernite,* after Torbern Bergmann, and Witherite after Dr. Withering (ibid., **1**, 103, 1790). The exact date of the former name does not appear; the first mention found is that by Karsten in 1793 (by him written *Torberite*), who states that Werner substituted *Chalcolite* for it; accepting this it must be at least earlier than 1788 (cf. ibid., **2**, 503, 1788). In 1789, Sage protested (J. Phys., **34**, p. 446) against the name Prehnite and the use of personal names in general as trivial. In 1790, Estner, a mineralogist of Vienna, issued a pamphlet against the Werner school, with the title "Freymüthige Gedanken über Herrn Inspector Werner's Verbesserungen in der Mineralogie," etc. (64 pp. 16mo, 1790), in which he makes light of Werner's labors in the science, and under the head of *Prehnite* ridiculed this method of creating a paternity, and providing the childless with children to hand down their names to posterity (p. 25). Such names were, however, too easily made, too pleasant, as a general thing, to give and receive, and withal too free from real objection, to be thus stopped off, and they have since become numerous, even Vienna contributing her full share toward their multiplication.

As a part of the history of mineralogical nomenclature, it may be here added that Werner, when it was proved that his *chalcolite* was an ore of uranium with but little copper, instead of a true ore of copper, dropped the name entirely, and called the mineral simply *Uranglimmer* (Uranium mica); and Karsten, in his reply to Abbé Estner (Berlin, 1793, 80 pp. 12mo), makes out of the necessary rejection of chalcolite an argument against chemical names, and in favor of names after persons, as the latter could never turn out erroneous in signification.

Werner, in an article written in defense of his introduction of this class of names (Bergm. J., **1**, 103, 1790), mentions the case of *Obsidian* (more properly *Obsian*) as a precedent from Pliny, Obsian being, as Pliny states, the reputed discoverer of the substance in Ethiopia. But this is not strictly an example. For Pliny uses *Obsian* not as a substantive, but as an adjective; the mineral was not *Obsian,* but *Obsian glass* or *Obsian stone; vitrum obsianum, lapis obsianus,* and *obsiana* [vitra], occurring in the course of the paragraph. The addition of the termination *ite* to Obsian would, according to mineralogical method, make a name equivalent to Pliny's *lapis obsianus.* Names of persons ending in *an* (as Octavian, Tertullian) were common among the Romans; and this is so far reason for avoiding the termination in names of stones.

Some critics question the existence of the reputed Obsius, and reject Pliny's explanation.

3. The ancient origin of this termination *ite,* its adoption for most of the names in modern mineralogy, its distinctive character and convenient application, make it evidently the true basis for uniformity in the nomenclature of the science.

4. If any other termination in addition is to be used, it should be so only *under system;* that is, it should be made characteristic of a particular natural group of species, and be invariably employed for the names in that group; and its use should not be a matter of choice or fancy with describers of species.

As a matter of fact, several other terminations are in use, but wholly without reference to any such system. The most common of them is *ine;* but it has not been employed for any particular division of minerals, and it could not now be so restricted; it belongs by adoption and long usage to chemistry, and should be left to that science.

5. In order then that the acquired uniformity may be attained, changes should be made in existing names, when it can be done without great inconvenience.

Names like *Quartz, Garnet, Gypsum, Realgar, Orpiment,* with the names of the metals and gems, which are part of general literature, must remain unaltered. *Mica* and *Feldspar,* equally old with Quartz, have become the names of *groups* of minerals, and are no longer applied to particular species. *Fluor* was written *fluorite* last century by Napione. *Blende,* although one of the number that might be allowed to stand among the exceptions, has already given place with some mineralogists to *Sphalerite,* a name proposed by Haidinger (because blende was applied also to other species) in 1845, and signifying *deception,* like Blende. Galena was written *Galenite* by von Kobell some years since. Orthoclase, Loxoclase, Oligoclase might be rightly lengthened to *Orthoclasite,* etc. But the termination *clase* (from the Greek for *fracture*) is peculiar to names of minerals, and the abbreviated form in use may be allowed to stand for species of the Feldspar group. Many other examples will be found by the reader in the pages of this volume.

In the course of the last century, when the science of minerals was taking shape, and progress in chemistry was helping it forward, there was an effort on one side to introduce, under the influence of Linnæus, the double names of Botany and Zoology; and on the other, under the influence of Cronstedt and Bergmann, names expressive of chemical composition, as far as it was ascertained; and the two methods have their advocates even now. But, at the same time, the necessity of single names was recognized by most of the early mineralogists; and in the spirit of the system which had made its appearance among the Greeks and Romans out of the genius of the Greek language, they almost uniformly adopted for the new names the termination *ite.*

Thus we have from Werner the names Torberite, Chalcolite, Graphite, Prehnite, Witherite, Boracite, Augite, Pistacite, Pinite, Aragonite, Apatite, Leucite, Cyanite (Kyanite); and from other sources in the same century, Zeolite, Actinolite, Tremolite, Coccolite, Arendalite, Baikalite, Melanite, Staurolite, Lepidolite, Cryolite, Chiastolite, Collyrite, Agalmatolite, Sommite, Moroxite, Pharmacolite, Strontianite, Delphinite, Titanite, Ceylanite, Gadolinite, Rubellite, Salite, Wernerite, Scapolite, Mellite, etc.

The termination *ine* was also adopted for a few names, as Tourmaline, Olivine, Mascagnine, Serpentine; and *an* in Vesuvian; but the great bulk of the names were systematically terminated in *ite*.

With the opening of the present century (in 1801), Haüy came forward with his great work on Crystallography, and in it he brought out a variety of new names that defy all system, having nothing of the system of the earlier science, and no substitute of his own. Forgetting that the unity of law which he had found in nature should be a feature of scientific language, he gave to his names the following terminations:

*ane*, in Cymophane; *ase*, in Euclase, Idocrase, Anatase, Dioptase; *aste*, in Pleonaste; *age*, in Diallage; *ene*, in Disthene, Sphene; *gene*, in Amphigene; *ide*, in Staurotide; *ime*, in Analcime; *ole*, in Amphibole; *ome*, in Aplome, Harmotome; *ose*, in Orthose; *ote*, in Actinote, Epidote; *yre*, in Dipyre; *ype*, in Mesotype. And the true mineralogical termination *ite* he admitted only in the few following: Axinite, Meionite, Pycnite, Stilbite, Grammatite.

Haüy had commanded so great and so general admiration by his brilliant discoveries in crystallography, and by the benefits which he had thus conferred on mineralogical science, that his names with their innovations were for the most part immediately accepted even beyond the limits of France, although a number of them were substitutes for those of other authors. Some of Werner's names were among the rejected; and a break was thus occasioned between German and French mineralogy, which will not be wholly removed until the rule of priority, properly restricted, shall be allowed to have sway.

The *substitutes* among Haüy's names in the 1st Edition of his Crystallography (1801) are the following:

Amphibole, for *Hornblende* of last century and earlier.

Orthose, for *Feldspar*.

Pyroxene, for *Augite* of Werner, and *Volcanite* of Delamétherie. [Delamétherie was a contemporary of Haüy at Paris, the author in 1792 of an edition of Mongez's *Manuel du Minéralogiste* (after Bergmann's Sciagraphia); in 1797, of an ambitious speculative work entitled *Théorie de la Terre*, the first two volumes of which consisted of a Treatise on Mineralogy; in 1811, 1812, of *Leçons de Minéralogie*, in 2 vols., and for a number of years principal editor of the *Journal de Physique*. He gave offense to Haüy by some of his early publications. Haüy's mineral Euclase is described in full by Delamétherie in the *Journal de Physique* for 1792 (some years in advance of Haüy's description of it), without crediting the name or anything else to Haüy; but five years later, in his *Théorie de la Terre*, he inserts the species with full credit to Haüy.]

Cymophane, for *Chrysoberyl* of Werner.

Idocrase, for *Vesuvian* of Werner.

Pleonaste, for *Ceylanite* of Delamétherie.

Disthene, for *Cyanite* of Werner.

Anatase, for *Octahedrite* of de Saussure, and *Oisanite* of Delamétherie.

Sphene, for *Titanite* of Klaproth.

Nepheline, for *Sommite* of Delamétherie.

Triphane, for *Spodumene* of d'Andrada.

Amphigene, for *Leucite* of Werner.

Actinote, for *Actinolite* of Kirwan, and *Zillerthite* of Delamétherie.

Epidote, for *Thallite* of Delamétherie, *Delphinite* of de Saussure, and *Arendalite* of Karsten.

Axinite, for *Yanolite* of Delamétherie.

Harmotome, for *Andreolite* of Delamétherie.

Grammatite, for *Tremolite* of Pini.

Staurotide, for *Staurolite* of Delamétherie, and *Grenatite* of de Saussure.

And, later, *Paranthine*, for *Scapolite* of d'Andrada, and *Rapidolite* of Abildgaard.

Part of the changes were made with good reason; but others were wholly unnecessary. Haüy was opposed to names from localities, and hence several of the displacements. He objected also to names based on variable characters, and characters not confined to the species. Moreover, as his pupil, Lucas, observes (in giving reasons for rejecting the name *Scapolite* and substituting *Paranthine*), "le vice du mot *lite*, qui s'applique à toutes les pierres, ne pouvoient plus convenir à cette substance du moment où elle seroit reconnue pour un espèce." Haüy's own names are remarkable, in general, for their indefiniteness of signification, which makes them etymologically nearly as good for one mineral as another, and very bad for almost none; as, for example, *Diallage*, which is from the Greek for *difference; Analcime*, from *weakness* in Greek; *Orthose*, from *straight* in Greek; *Epidote*, from *increase* in Greek; *Anatase*, from *erection* in Greek, interpreted by him as equivalent to *length; Idocrase*, from *to see a mixture* in Greek, etc. His name *Pyroxene*, which he defines *hôte ou étranger dans le domaine du feu*, is an unfortunate exception, as often remarked, the mineral being the most common and universal constituent of igneous rocks.

Beudant succeeded Haüy, and had the same want of system in his ideas of nomenclature. Finding occasion to name various mineral species which till then had only chemical names, he adopted Haüy's method of miscellaneous terminations, but indulged in it with less taste and judgment, and with little knowledge of the rules of etymology. In his work we find the termination *ese*, in Apherese, Aphanese, Neoctese, Acerdese, Mimetese; *ise*, in Leberkise, Sperkise, Harkise (only German words Gallicized), Melaconise, Zinconise, Crocoise, Stibiconise, Uraconise; *ose*, in Argyrose, Argyrythrose, Psaturose, Aphthalose, Rhodalose, Siderose, Elasmose, Exanthalose, Cyanose, Melinose, Disomose; *ase*, in Neoptase, Discrase; *ime*, in Ypoleime; *ele*, in Exitele; while names ending in *ine* are greatly multiplied.

In Germany, the tendency has always been to uniformity through the adoption of the termination *ite*. Breithaupt has been somewhat lawless, giving the science his Plinian, Alumian, Sardinian, Asbolan, etc.; his Castor and Pollux; Glaucodot, Homichlin, Orthoclase, Xanthocon, etc.; still, far the larger part of his numerous names are rightly terminated. Haidinger's many names are always right and good.

6. In forming names from the Greek or Latin the termination *ite* is added to the genitive form after dropping the vowel or vowels of the last syllable, and any following letters. Thus, μέλας makes μέλανος (*melanos*) in the genitive, and gives the name *melanite*. The Greek language is the most approved source of names.

7. In compounding Greek words the same elision of the Greek genitive is made for the first word in the compound, provided the second word begins with a vowel; if not, the letter *o* is inserted. Thus, from πῦρ, genitive πυρός (*puros*), and ὀρθός (*orthos*), comes pyrorthite; and from the same and ξένος (*xenos*) comes pyroxene.

8. The liberty is sometimes taken in the case of long compounds to drop a syllable, and when done with judgment it is not objectionable; thus *melacanite* has been accepted in place of *melanoconite*. But *magnoferrite* (as if from the Latin *magnus*, great, and ferrum, *iron*), for a compound of *magnesiă* and iron, or *calcimangite* for one containing lime and *manganese*, are bad.

9. In the transfer of Greek words into Latin or English, the κ (*k*) becomes *c*, and the υ (*u*) becomes *y*.

10. In the formation of the names of minerals, the addition of the termination *ite* to proper names in modern languages (names of places, persons, etc.), or names of characteristic chemical constituents, is allowable; but making this or any other syllable a suffix to *common* words in such languages is barbarous.

11. Names made half of Greek and half of Latin are objectionable; but names that are half of Greek or Latin and half of a modern language are intolerable.

12. *Law of Priority.*—The law of priority has the same claim to recognition in mineralogy as in the other natural sciences. Its purpose is primarily to secure the stability, purity, and perfection of science, and not to insure credit to authors.

13. *Limitations of the Law of Priority.*—The following are cases in which a name having priority may properly be set aside:

*a.* When the name is identical with the accepted name of another mineral of earlier date.

*b.* When it is glaringly false in signification; as when a red mineral is declared in its name to be black; e.g., *Melanochroite* (p. 914).

*c.* When it is put forth without a description.

*d.* When published with a description so incorrect that a recognition of the mineral by means of it is impossible; and in consequence, and because also of the rarity of specimens, the same species is described under another name without the describer's knowledge of the mineral bearing the former name. When, on the contrary, a badly described but well-known old mineral is redescribed correctly, there is no propriety in the new describer changing the old name.

*e.* When the name is based on an uncharacteristic variety of the species, Thus *Sagenite* was properly set aside for *Rutile*.

*f.* When the name is based upon a variety so important that the variety is best left to retain its original name; particularly where this and other varieties of the species, introduced originally as separate species, are afterwards shown by investigation to belong to a common species. Thus, the earlier name *Augite* is properly retained as the name of a variety, and Haüy's later name *Pyroxene* accepted for the group.

*g.* When a name becomes the designation of a group of species: as *Mica*, *Chlorite*.

*h.* When the name is badly formed, or the parts are badly put together: as when the terminal *s* of a Greek word is retained in the derivative; e.g., *aphanese* from ἀφανής; *Melaconise* from the Greek for *black* and κόνις; *Rhodalose* from the Greek for *rose-colored* and ἅλος (*halos*), the genitive of αλς, *salt*. The last word is bad not only in termination but in wanting an *h* before the *a*, and strictly an *o* after the *d*. Also *Siderose* (spathic iron), *Argyrose* (silver glance), *Chalcosine* (copper glance), from, respectively, σίδηρος, ἄργυρος, χαλκός. The ancient Greeks showed us how the derivatives from these words should terminate by writing them *Sideritis*, *Argyritis*, *Chalcitis*.

Ignorance or carelessness should not be allowed to give perpetuity to its blunders under any law of priority.

*i.* When a name is intolerable for the reasons mentioned in §§ 10, 11, as Harkise, from the German Haarkies (hair-pyrites); *Kupaphrite*, from the German *Kupferschaum; Bleinierite*, from the German *Blei-Niere*.

*j.* When a name has been lost sight of and has found no one to assert its claim for a period of more than fifty years; especially if the later name adopted for the species has become intimately incorporated with the structure of the science, or with the nomenclature of rocks. Thus, although *Thallite* and *Delphinite* antedate *Epidote*, it is not for the good of Science that Epidote should be thrown aside. But where a name has not this importance, and is unexceptionable, the law of priority may be allowed to have its course.

*k*. Where the adopted system of nomenclature in the science is not conformed to. In accordance with this last principle, the author, believing that the system demands that the names of species should have as far as possible, as above explained, the common termination *ite*, has changed, accordingly, a number of the names in the course of this volume.

14. It has appeared desirable that the names of rocks should have some difference of form from those of minerals. To secure this end, the author has written the final syllable *ite* of such names with a *y;* thus Diorite, Eurite, Tonalite, etc., are written *Dioryte*, *Euryte*, *Tonalyte*. The *y* is already in the name *Trachyte*. The author has allowed Granite and Syenite to remain as they are ordinarily written, since they are familiar names in common as well as in scientific literature.

See further, on Nomenclature, the excellent Mineral-Namen of von Kobell. A recent discussion of the subject has been given by Dr. H. Hugo A. Francke (Ueber die mineralogische Nomenclatur, 124 pp. 8vo. Berlin, 1890).

The following paragraphs on the history of the Silicates (from 5th Ed., pp. 204–206) are an important addition to the subject of mineral-nomenclature.

*Note on the History of the Silicates.*—In the work of the Swedish mineralogist Wallerius, of 1747, silicates as such are unrecognized, and the only species of those now so called which are described are the gems that passed under the names of *emerald*, *beryl*, *topaz*, *hyacinth*, *chrysolite*, *garnet ; clays* of various kinds and names ; *mica*, *talc*, *serpentine*, *amianthus*, *asbestus*, *feldspar*, and the convenient pocket for various undetermined heavy stones, named *Corneus*—the *Hornbärg* of the Swedish mineralogist, and *Roche de Corne* of his French translator, and which embraced *Skiörl* (*Schörl* of the Germans) as a prominent part of it. Quartz (Kieselsten, or Silex) in its many varieties, with opal, made up a large part of the non-metallic division of the science, occupying 30 pages out of 200. Feldspar is placed in the genus Spatum, as *Spatum pyrimachum* (or scintillating spar) alongside of fluor, Iceland spar, and heavy spar ; and sapphire and the other precious stones are in the group of Gems. All of these species excepting feldspar had special names in Pliny's time; and feldspar is distinctly referred to in Agricola as "Silex ex eo ictu ferri facile ignis elicitur, in cubis aliisque figuris intersectis constans" (p. 314, 1546).

Cronstedt's work of 1758 includes with the preceding the species *Zeolite*, a recent discovery of his own (1756); but adds no others. He shows, however, his acumen in making his group of *Kiesel-Arter* (siliceous minerals) to include not only the varieties of quartz, but also feldspar and the gems above enumerated (and his adding to it the diamond is not surprising). Garnet and schörl are left outside, and make the two species of his *Granat-Arter; Mica* (Glimmer-Arter) and *Asbestus* (Asbest-Arter), with Ler-Arter (clay minerals), are the other independent groups. Transparent tourmalines from Ceylon were among the gems of the day, having been first introduced into Europe in 1707 or before, but they are not distinctly mentioned by Cronstedt or Wallerius.

The group of Schörl increased in its varieties for the next twenty-five years, and after that became prolific in species, and much of the history of mineralogy is involved in its various phases. The following observations make, therefore, an introduction to the synonymy of many minerals beyond.

The *Corneus*, or *Hornbärg*, of Wallerius included a variety of hard, cheap or worthless stones, rather heavy, mostly of dark colors from black to dull green. The name alludes to a resemblance to horn in the aspect of some of the kinds. To *Corneus solidus* belonged the massive, compact, flinty rocks of black and lighter shades; also petrosilex (or *Hälleflinta* of the Swedes, which means *false flint*) of different shades; and massive hornblende ("granulis compactis"), though the name hornblende was, by a mistake of its German use, given by Wallerius to a black zinc-blende alone. His *Corneus fissilis* embraced lamellar forms of hornblende and pyroxene, and some slaty rocks. While *Corneus crystallisatus* was his *Skiörl*, which comprised opaque tourmalines, and other prismatic minerals of black, brown, green, and reddish colors, as hornblende, actinolite, and perhaps pyroxene, and at the head of the list basalt, and basanite or Lydian stone.

Cronstedt's *Skörl* made up his genus *Basaltes*, and was nearly synonymous with the *Corneus crystallisatus* of Wallerius. Its varieties were better defined; and to massive, lamellar, and columnar hornblende, actinolite and pyroxene and crystallized opaque tourmaline were added; and in an appendix to the species, cruciform staurotide. The name *Hornblende* is applied only to the massive variety or rock which Cronstedt made a *bole*, and called *Bolus induratis particulis squamosis ;* it probably covered other similar stones.

J. Hill in his work on Fossils, published in London, and according to the title-page in 1771 (though de Lisle says it was not issued until 1772), says of the "Shirls," that "as to size we see them from that of barley corn up to the Giant's Causeway," and the columns of the latter he calls "Irish Shirl," or "Basaltes Hibernicus." The group contains also macle or chiostolite from Andalusia, besides tourmaline, etc.

In the editions of Wallerius of 1772 and 1778 there is a little advance beyond the first as regards the number and classification of the species. Cronstedt is followed in the position of feldspar, and in the name "Basaltes" for the schörls; and Corneus is restricted to massive, fibrous, and coarse columnar stones, among which stands "hornblende" as *Corneus spathosus*, and "trapp" as *Corneus trapezius*.

At this period de Lisle brought crystallography to bear on the subject. But while making known new distinctions, he did not appreciate their full value, or the precision required for thorough work. As a consequence, the group of Schörls (or Schorls, as he writes the word in his later treatise of 1783) reached its greatest extension, although in a partly divided state. He early pronounced basaltic columns no crystals, and dropped off this excrescence. He showed in 1772 that the gem tourmaline, his *Transparent rhomboidal schorl*, was identical in form with the common black schorl. But still he made the latter a distinct *species*, his *Opaque rhomboidal schorl*, and included in it, along with black or opaque tourmaline, crystals of hornblende, augite, octahedrite from Oisans, rutile (needles in quartz), and, as a white variety, thin twins of albite, whose relation to feldspar he did not perceive; and even hexagonal nephelite from Vesuvius has a passing remark under this head. Axinite, then a novelty from Dauphiny, was made a short lenticular variety of *Transparent rhomboidal schorl*, or tourmaline, its *rhomboidal* planes proving to his eye the relationship. The massive mineral called *Hornblende*, or *Roche de Corne*, referred by Cronstedt to *Bole*, he annexes to Schorl as a massive or semi-crystallized kind, but makes it a separate species, *Schorl argileux*, although apparently appreciating that it was little entitled to the distinction. *Schorl cruciforme* was his last species in the group, and to it were referred both andalusite and staurolite—the latter his *Pierre de croix*, with the prismatic angle of 130° by his measurement; and the former, *Macle basaltique*, with an angle of 95°. The garnets and schorls were placed in a common division, as done by Cronstedt, and garnet was made the first species, with tourmaline the second and "cruciform schorl" the fifth. Garnet included the "white garnet," as it was called, of Vesuvius (leucite), first observed by Ferber in 1772. Besides these Silicates, de Lisle's work has its several groups of Gems, Feldspar, Argillaceous Minerals (embracing mica, asbestus, talc, serpentine), Zeolite, and Quartz. Labradorite, from Labrador (first brought to Europe about 1770), stands as a variety of feldspar, to which it had been referred by Werner; idocrase, of which many figures are given by him (first described and figured by Cappeler in 1722), meionite (hyacintes blanches), from Somma, and harmotome from Andreasberg (his *hyacinte blanche cruciforme*, made calcareous spar by v. Born in 1775, who first mentions and figures it, but a hyacinth-like *siliceous* species by Bergmann in 1780), are placed with zircon as kinds of *hyacinth*.

After de Lisle, as chemistry and crystallography made progress, the disintegration of the great Schorl group went rapidly forward, until the only thing left to it was common tourmaline; and now the name, once so important, has become a mere mineralogical relic. In Werner's system of 1789, as published by Hoffmann (Bergm. J., **1**, 369, 1789), Schörl includes only the species Tourmaline as it now stands. The *Kieselarten*, or Siliceous species (commencing with the diamond still), comprised the different gems; among which stands chrysoberyl (the modern), and, as distinct species, axinite, prehnite, hornblende of various kinds, with feldspar, mica, chlorite, the clays, etc.; while under *Talkarten*, or Magnesian species, there are kyanite, actinolite, with asbestus, talc, serpentine, nephrite, etc.

Silica was first proved to be a chemical constituent of many mineral species by Bergmann; and in his Opuscula (1780) and his Sciagraphia Regni Mineralis (1782) he distinguishes, after analyses by himself (made by fusion with potash, a method of his own), the following minerals as siliceous compounds of alumina, with or without lime or magnesia, namely, topaz, emerald, garnet, schörl (black tourmaline), hornblende, mica, zeolite from Iceland, feldspar, and the clays; and as essentially magnesian silicates, containing lime and a little iron, and little or no alumina, actinolite, asbestus (mountain cork and mountain leather), amianthus, steatite. These were the investigations that commenced the disbanding of the schorls, and before Werner's system of 1789 was published, many other analyses, more or less imperfect, had already been made by Wiegleb, Klaproth, Achard, Heyer, Mayer, Höpfner, Pelletier, and other chemists of the day.

The word *Schörl* of the Germans has been supposed to be derived from the name of a locality of the mineral, *Schorlau* (meaning Schörl-village) in Germany. But Prof. Naumann said (in a letter to J. D. Dana, 1867) that it is more likely that the name is a miner's term of unknown origin, and that the village got its name from the occurrence there of the schörl. Some German mineralogists have pronounced it of Swedish origin, and as first used by Cronstedt. But it occurs in Brückmann's Magnalia Dei, published at Braunschweig in 1727, on page 175, where it is spelt *schirl*. It exists also still earlier, as the author has found, in Ercker's Aula Subterranea, first published in 1595, *shurl* and wolfram being spoken of as among the rejected material in auriferous washings; and again in the yet older work of Gesner, De Rerum Foss, etc., 1565, p. 87, where schurl (misspelt? *schrul*) is given as the German for "Lapilli nigri steriles" of a tin vein, which, "quando cum lapillis plumbi candidi [or tin] coquuntur plumbum consumunt," etc.; again, in Matthesius's Sarepta, 1562, in the 9th "Predigt," where "Schurl" is quite fully described, and also in the next paragraph, "Wolffrumb." The name Schörl (or Schurl) was at that time used quite indefinitely for the *sterile* (or metallurgically worthless) black little stones ("nigri lapilli") accompanying tin ore and gold, especially the former; and, as they were among the refuse of the ore-washings, Adelung suggests that Schörl may have come from the old German word *Schor*, meaning *impurities*, or *refuse*.

## V. BIBLIOGRAPHY.

The following catalogue contains the titles of the independent works and of most of the periodicals which are referred to in the following pages, with their abbreviated forms. Some titles also are added of works consulted but not referred to.

Titles of *Inaugural Dissertations* (chiefly German) are not specially mentioned in the Bibliography, though in most cases the originals have been in the hands of the author. For the benefit of those who have not access to these and to the rarer portion of recent periodical literature in general, it may be noted that full abstracts are usually to be found in the Jahrbuch für Mineralogie (**Jb. Min.**) and particularly (since 1877) in Groth's Zeitschrift (**Zs. Kr.**); further, abstracts of chemical papers are generally given in the Jahresbericht für Chemie (**JB. Ch.**), also in the Journal of the Chemical Society (**J. Ch. Soc.**) and elsewhere. Many more titles could have been introduced of scientific periodicals, particularly of Scientific Societies, but it would only greatly overburden an already long list if they were all included. The explanation of the general system of abbreviations adopted is so full that references will be intelligible even when the periodical in question is not included in the list. In this connection, attention may be called to the excellent Catalogues of scientific periodicals prepared by Scudder* (1879) and by Bolton † (1885).

In the references, the number of the volume is uniformly printed in heavy-faced type (**9**). In the case of periodicals, the number of the series (in the last edition denoted by Roman numerals, I, II, III, etc.) is omitted for the sake of brevity, as not essential, since the *date* is always given. In general it may be mentioned that the addition of the date to a reference much increases its value. The number of the section, e.g. of an Academy, to which the publication belongs is indicated by a number in parentheses following the volume, as *Ber. Ak. Wien*, **50** (1), etc.

The statement made in the Preface is repeated here, that authors quoted have been actually consulted in the original; in a few cases when the original source was not accessible, this is given in brackets, [ ], while the authority used follows.

The abbreviations of the more important words in the abbreviated titles are given after the Bibliography (p. lxi *et seq.*), with also the abbreviations of the names of the States in the United States; and finally the abbreviations of proper names.

### 1. PERIODICALS NOT ISSUED BY SCIENTIFIC SOCIETIES.

**Afh., or Afhandl.** Afhandlingar i Fisik, Kemi och Mineralogie, etc., utgifne af Hisinger & Berzelius. Vol. 1, 1806; 2, '07; 3, '10; 4, '15; 5, 6, '18.

**Am. Ch. J.** American Chemical Journal. Edited by Ira Remsen, Baltimore (Johns Hopkins University). Begun in 1879. One volume annually in 6 numbers. Vol. 1, 1879; 12, 1891. Index, vols. 1-10, 1890.

---

* Scientific Serials of all Countries, including the Transactions of Learned Societies, in the Natural, Physical, and Mathematical Sciences, 1633-1876. By Samuel H. Scudder. Cambridge, 1879.

† A Catalogue of Scientific and Technical Periodicals, 1665-1882, by H. Carrington Bolton. Washington, 1885 (Smithsonian Miscellaneous Contributions, 514).

**Am. J. Sc.** American Journal of Science. 1st series of 50 volumes, 8vo; conducted by B. Silliman, 1818–1839; with B. Silliman, Jr., from 1840. Four numbers to vol. 1, and two to subsequent vols. Vol. 1, No. 1, Aug., 1818; No. 2, Jan., '19; No. 3, Mar., '19; No. 4, June, '18; vol. 2, Ap., Nov., '20; 3, Feb., May, '21; 4, Oct., Feb., '21, '22; 5, June, Sept., '22; 6, Jan., May, '23; 7, Nov., Feb., '23, '24; 8, May, Aug., '24; 9, Feb., June, '25; 10, Oct., Feb., '25, '26; 11, June, Oct., '26; 12, 13, Mar., June, Sept., Dec., '27; afterward regularly on the first of April, July, Oct., Jan.; vols. 14, 15, in '28, '28–'29; 24, 25, in '33, '33–'34; 34, 35, in '38, '38–'39; then regularly, Jan., May, July, Oct., 36, 37, in '39; 38, 39, in '40; 48, 49, in '50; 50, Index volume.

2d ser., by the same and James D. Dana, until 1865, after which, by B. Silliman and James D. Dana; from 1851, aided by A. Gray and W. Gibbs, and later by other co-editors. 2 vols. ann.; 1, 2, 1846; 11, 12, '51; 21, 22, '56; 31, 32, '61; 41, 42, '66; whence, 49, 50, 1870. An index to each 10 vols. in vol. 10, 20, 30, etc.

3d ser. from 1871 in monthly numbers, by James D. Dana and B. Silliman until 1875; then by the same and E. S. Dana, and from 1885 by James D. and E. S. Dana. Vol. 1, 2, '71; 11, 12, '76; 21, 22, '81; 31, 32, '86; 41, 42, '91. An index to each 10 volumes issued (sometimes separately) with vol. 10, 20, 30, etc. The title was "American Journal of Science and Arts" until 1880.

**Amer. Geol.** The American Geologist. 8vo, Minneapolis. Vol. 1, 2, '88; 7, 8, '91.

**Amer. Nat.** The American Naturalist. 1 vol. annually. 8vo, Salem, and later Philadelphia. Vol. 1, '68; 25, '91.

**Ann. Ch.** Annales de Chimie. 8vo, Paris, vols. 1–3, 1789; 4–7, '90; 8–11, '91; 12–15, '92; 16–18, '93; 19–24, '97; 25–27, '98; 28–31, '99; then regularly 4 v. ann.; 32–35, 1800; 52–55; '05; 72–75, '10; 92–95, 96, '15. Index to vols. 31 to 60 inclusive. Continued in the Ann. Ch. Phys. (q.v.).

**Ann. Ch. Pharm.** See **Lieb. Ann.**

**Ann. Ch. Phys.** Annales de Chèmie et de Physique; at first by Gay Lussac et Arago. 8vo, Paris; 3 vols. ann.; 1–3, 1816; 16–18, '21; 31–33, '26; 46–48, '31; 61–63, '36; 73–75, '40. Vols. 67–75 made 2d ser., and numbered 1–9. 3d ser., 1–3, '41; 16–18, '46; 31–33, '51; 46–48, '56; 61–63, '61; 67–69, '63. 4th ser., 1–3, 1864; 16–18, '69; 28–30, '73. 5th ser., 1–3, '74; 22–24, '81; 28–30, '83. 6th ser., 1–3, '84; 22–24, '91.

Index 1st ser. to vols. 1–30; 31–60; 61–90. To 2d ser., 1–30; 31–75. To 3d ser., 1–30; 31–69. 4th ser., 1–30. 5th ser., 1–30.

**Ann. Mines.** Annales des Mines. 8vo, Paris. Begun in 1816 as sequel to Journal des Mines; 1 vol. a year until 1825, and subsequently 2 vols. a year. Vol. 1, 1816; 6, '21; 10, 11, '25; 12, 13, '26. 2d ser., 1, 2, '27; 8, last. 3d ser., 1, 2, '32; 19, 20, '41. 4th ser., 1, 2, '42; 19, 20, '51. 5th ser., 1, 2, '52; 19. 20, '61. 6th ser., 1, 2, '62; 19, 20, '71. 7th ser., 1, 2, '72; 19, 20, '81. 8th ser., 1, 2, '82; 19, 20, '91. Indexes to the different series.

**Ann. Mus. d'Hist. Nat.** Annales du Muséum d'histoire naturelle par les Professeurs de cet établissement, MM. Haüy, Fourcroy, Vauquelin, Desfontaines, A. L. de Jussieu, Geoffroy, Lacepède, etc. 4to, Paris; vols. 1–20, 2 a year, 1803–1815.

**Ann. Phil.** Annals of Philosophy. 2 vols. ann., 8vo, London. 1st ser. by Thos. Thomson; vols. 1, 2, 1813: 11, 12, '18; 15, 16, '20. 2d ser., vols. 1, 2, 1821; 11, 12, '26. Then merged in Phil. Mag. (q.v.).

**Arch. Math. Nat.** Archiv for Mathematik og Naturvidenskab, 8vo, Kristiania. Begun in 1876.

**Arch. Sc. phys. nat.** See **Bibl. Univ.**

**B. H. Ztg.** Berg- und hüttenmännische Zeitung. 4to, Leipzig, 1 vol. ann. Begun by Hartmann, and sometimes called Hartmann's Zeitung. Vol. 1, 1842; 4, '45; 9, '50; 14, '55; 19, '60; 24, '65; 29, '70, etc.

**Baumg. Zs.** Zeitschrift f. Physik und Mathematik; edited by Baumgartner and Ettingshausen. 10 vols., 8vo, 1826–1832, Vienna.

**Bergm. J.** Bergmännisches Journal; ed. by A. W. Köhler. 12mo, Freyberg, Sax. 1, 2, 1788; 1, 2, '89; so to '92; 1, 2, '93, by Köhler and Hoffmann. Afterward, Neues Bergm. J., of K. & H.; 1, 1795; 2, '98; 3, 1802; 4, '16. Contains papers by Werner, Hoffmann, Klaproth, and much on mineralogy.

**Berz. JB.** See **JB. Ch.**

**Bibl. Univ.** Bibliothèque Universelle de Genève. Begun in 1816. In 1846, 4th series of 36 vols. commenced, and the scientific part of the Review takes the title, *Archives des Sciences physiques et naturelles.* 5th series commenced in 1858. Vols. 1–3, '58; 31–33, '68; 61–64, '78. New ser., 1, 2, '79; 15, 16, '86.

**Bruce Am. Min. J.** The American Mineralogical Journal; conducted by Archibald Bruce, M.D. Only 1 vol., 8vo. Begun Jan., 1810; No. 1, 62 pp., 1810, and 2, to p. 126, '10; 3, to p. 190, '11; 4, to end, p. 270, '13.

**Can. Nat.** Canadian Naturalist and Geologist. 8vo, Montreal. Vol. 1, 1856; 5, '61; 8, '63; 2d ser., vol. 1, '64; 2, '65; 3, '66; 10, '81–'83, etc.

**Can. J.** Canadian Journal of Industry, Science, and Art. Toronto, Canada. 2d ser., vol. 1, 1856; 5, '60; 10, '65; 11, '66, '67; 15, '76–'78.

**Ch. Gaz.** Chemical Gazette, by W. Francis. 8vo, London. 1 vol, ann. after vol. 1, of 1842 17, '59.

**Ch. News.** Chemical News; edited by W. Crookes. Sm. 4to, London. 2 v. ann.; vols. 1, 2, 1860; 11, 12, '65; 21, 22, '70; 41, 42, '80; 61, 62, '90.

**Crell's Ann.** Chemische Annalen; by L. Crell. 40 vols., 12mo, Helmstadt u. Leipzig. Vols. numbered 1, 2, for each year, from 1784 to 1803 inclusive.

**Dingler J.** Polytechnisches Journal; by J. G. & E. M. Dingler. 3 vols. ann., 8vo, Augsburg. Begun in 1820; vol. 187, in 1868, etc.

**Dublin Q. J. Sc.** Dublin Quarterly Journal of Science; edited by Rev. S. Haughton. 6 vols. 8vo, 1861–'66, Dublin.

**Ed. J. Sc.** Edinburgh Journal of Science; edited by D. Brewster (~~often called~~ Brewster's J.). 8vo, Edinburgh, 2 vols. ann. 1st ser., vol. 1, 1824; 2, 3, '25; 6, 7, '27; 10, '29. 2d ser., vol. 1, 1829; 2, 3, '30; 4, 5, '31; 6, '32. Merged in Phil. Mag.

**Ed. Phil. J.** Edinburgh Philosophical Journal; edited by Brewster and Jameson. 8vo, 2 vols. ann.; vol. 1, 1819; 2, 3, '20; 6, 7, '22; 10, '24; edited by Jameson alone, 11, 1824; 12, 13, '25; 14, '26. Becomes Ed. N. Phil. J. (q.v.).

**Ed. N. Phil. J.** Edinburgh New Philosophical Journal; edited by Prof. Jameson (often called Jameson's Journal. 8vo, 2 vols. ann. 1st ser., vol. 1, 1826; 2, 3, '27; 12, 13, '32; 22, 23, '37; 32, 33, '42; 42, 43, '47; 52, 53, '52; 56, 57, '54. 2d ser., vols. 1, 2, 1855; 11, 12, '60; 19, 20, '64. Here ends.

**Eng. Mng. J.** Engineering and Mining Journal. 4to, published weekly. New York. Begun in 1866. Vols. 51, 52, 1891. Before 1872, Am. Journal of Mining, Milling, etc.

**Erman's Arch.** Archiv für wissenschaftliche Russland. Begun in 1841; 1 vol. ann. Vol. 1, 1841; 11, '51; 21, '61, etc.

**Gehlen's J.** Neues allg. Journal der Chemie; by A. F. Gehlen. 6 vols., Berlin; 1, 1803; 2, 3, '04; 6, '06. 2d ser., under the title Journal für die Chemie und Physik und Mineralogie, 9 vols., Berlin: 1, 2, 1806; 5, 6, '08; 9, '10. Afterward, Schweigger's Journal (q.v.) began at Nuremberg.

**Geol. Mag.** The Geological Magazine, or Monthly Journal of Geology. In monthly numbers. London. Begun in 1864; vol. 10, 1873; Decade II, vol. 1, '74; 10, '83. Decade III, vol. 1, '84; 8, 91. Preceded by The Geologist. 1858–63.

**Gilb. Ann.** Annalen der Physik; conducted by L. W. Gilbert. 8vo, Leipzig, 30 vols.; 1st series, 1799–1808; then 30 vols., 2d ser., 1809–'18; then Annalen d. Phys. und der Physikalischen Chemie, 16 vols., 3d ser., 1819–'23. The vols. of the several series usually counted consecutively; 1, 2, 1799; afterward 3 vols. a year, 3–6, 1800; 13–15, '03; 28–30, '08; 43–5, '13; 58–60, '18; 73–5, '23; 76, '24. Afterward continued as Poggendorff's Annalen, see **Pogg.**

**Giorn. Min.** Giornale di Mineralogia, Cristallografia e Petrografia, diretto dal Dr. F. Sansoni. Milan. Begun in 1890; vol. 2, 1891.

**Groth's Zeitschr.** See **Zs. Kr.**

**Haid., Nat. Abh. Wien.** Naturwissenschaftliche Abhandlungen. von Haidinger. 4to. Vols 1–4, 1847–'51.

**J. Mines,** or **J. d. M.** Journal des Mines. 8vo, Paris. In monthly nos. 2 v. ann.; 1, 2, 1797; 11, 12, 1802; 21, 22, '07; 31, 32, '12; 37, 38, '15. Continued in Annales des Mines (q v.).

**J. de Phys.,** or **J. Phys.** Journal de Physique. 4to, Paris, 2 vols. ann. Edited by Abbé Rozier (and hence called Rozier's J.), for vols. 1-43 (for a time with also Mongez, Jr.); by Delamétherie for vols. 44–84; and afterward by Blainville. Two introductory vols., 1771, 1772; vols. 1, 2, 1773; 11, 12, '78; 22, 23, '83; 32, 33, '88; 42, 43, '93; 44, 45, '94 (French Revolution); 46, 47, '98; 56, 57, 1803; 66, 67, '08; 76, 77, '13; 86, 87, '18; 94, 95, '22; 96, 1823.

**J. Phys.** Journal de Physique. Paris. Begun in 1872. One vol. annually. Vol. 1, 1872; 10, 1881. 2d ser., vol. 1, 1882; 10, 1891. Distinguished from the preceding by the date.

**J. pr. Ch.** Journal für praktische Chemie. 8vo, Leipzig, 3 vols. ann. Preceded by J. f. pr. und ökonomische Chemie, 18 vols. 8vo, 3 vols ann., begun in 1828. Begun in 1834; first edited by Erdmann & Schweigger-Seidel (see Schweigger J.); from 1838 by E. & Marchand; from 1852, by E. & Werther. Vols. 1–3, 1834; 19–21, '40; 34–36, '45; 49–51, '50; 64–66, '55; 79–81, '60; 94–96, '65; 109–111, '70. 2d ser. begun in 1870, vol. 1, 2, '70; 3, 4, '71; 23, 24, '81; 43, 44, '91.

**Arsb.**
**Jahresb.**
**JB. Ch.**
Årsberättelser om framstegen i Kemi och Mineralogi, af Jac. Berzelius. In German, Jahresbericht über die Fortschritte der Chemie und Mineralogie. 8vo; usually designated by the year. Commenced with 1821. Vol. 1, 1821; 11, '31; 21, '41; 30, 1850; the last three vols. by Svanberg. Continued in the Giessen Jahresbericht, issued by Liebig & Kopp, from 1847 to '56; by F. Zamminer, '57; Kopp & Will, '58; and Will alone from '63 on. The first vol. covers the years 1847, '48.

**Jb. Min.** Jahrbuch für Mineralogie, Geognosie, Geologie, und Petrefaktenkunde; edited by K. C. v. Leonhard & H. G. Bronn. 8vo, Heidelberg, 1 vol. ann. 1830–32, 4 Nos. a year; after '32, 6 Nos., and called *Neues Jahrbuch*, etc.

Since 1880 two volumes of three numbers each annually, the abstracts (**Ref.**) with independent paging. Also Beilage Band (**Beil.** or **Beil.-Bd.**), 1, 1881, 7, 1890–91. Index (Allg. Repertorium), 1850–59, 1860–'69, 1870–'79, 1880–'89, 1880–'84, and Beil.-Bd. 1, 2 (1885); 1885–'89, and Beil.-Bd. 3–6 (1891).

**Karst. Arch Min.** Archiv für Mineralogie, Geognosie, Bergbau und Hüttenkunde. 26 vols. 8vo, 1829–1855, Berlin. Edited for vols. 1–10 by C. J. B. Karsten; later by Karsten & v. Dechen.

**Kastn. Arch. Nat.** Archiv für die gesammte Naturlehre ; edited by K. W. G. Kastner. 8vo, Nürnberg. 27 vols., 3 vols. ann., 1824–'35.

**Kell. & Tiedm.** Nordamerikanischer Monatsbericht für Natur- und Heilkunde ; edited by Dr. W. Keller & Dr. H. Tiedemann. 4 vols., 8vo, Philadelphia. Vol. 1, 1850 ; 2, 3, '51 ; 4, '52.

**Lempe's Mag.** Magazin für die Bergbaukunde, by J. F. Lempe. 8vo, Dresden. Vol. 1, 1785; 2, 3. '86; 4, '87; then 1 vol. ann. till 11, '94; 12, '98; 13, '99.

**Lieb. Ann.** Annalen der Chemie und Pharmacie: by Wöhler and Liebig; from vol. 77, by Wöhler, Liebig, and Kopp, and called *new series.* 8vo, Leipzig and Heidelberg. 4 vols. (and later 4 to 6 or 7) ann. Vols. 1–4, 1832; 13–16, '35; 33–36, '40; 53–56, 45; 73–76, '50; 93–96, '55; 113–116, '60; 133–136, '65; 153–156, '70; 191–194, '78; 195–200, '79; 255–260, '90. Supplementband, 1, 1861; 2. '62, '63; 3, '64; 4. '65, '66; 7, '70; 8, '72.

With vol. 173 the title was changed to Liebig's Annalen der Chemie and the reference to the new series was dropped. Index to vols. 1–100, '61; 101–116, '61; 117–164, '74.

**L'Institut.** L'Institut, a weekly journal in small fol., Paris, 1 vol. ann.; begun in 1832.

**Mag. Nat. Helvet.** Magazin für die Naturkunde Helvetiens; herausg. A. Höpfner, Zürich. Begun in 1787.

**Min. Mag.** See p. l.

**Min. Mitth.** Mineralogische Mittheilungen gesammelt von G. Tschermak. Begun in 1871 as Beilage zum Jahrbuche der k. k. geol. Reichsanstalt. Since 1878 published separately (in smaller form) as Mineralogische und Petrographische Mittheilungen. Vol. 1, 1878; 11, 1890. Index, vols. 1–10, 1890. Edited since 1889 by F. Becke.

**Moll's Efem.** Efemeriden der Berg- und Hüttenkunde; edited by C. E. von Moll. 5 vols.; 1, 1805, at München; afterward at Nürnberg, 2, '06; 3, '07; 4, '08; 5, '09. Preceded by v. Moll's Jahrb. f. B. H., Salzburg, 5 vols., 1797–1801; and Annalen id., Salzburg, 3 vols., 1802–'04.

**Naturaleza.** La Naturaleza, Periodico cientifico, Mexico. Begun in 1869; vol. 7, '84–'87. 2d ser., vol. 1, '87–'91.

**Nature.** A weekly illustrated Journal of Science. London. Commenced in Nov. 1869, in weekly numbers. Vol. 1, Nov. '69–April '70; 2, May–Nov. '70; 10, May–Oct. '74; 20, May–Oct. '79; 30, May–Oct. '84; 40, May–Oct. '89; 44, May–Oct. '91.

**Nicholson's J.** Journal of Natural Philosophy, Chemistry, and the Arts; by Wm. Nicholson. London, 1st ser., 5 vols., 4to, vol. 1, 1797; 5, 1801. 2d ser., 36 vols. 8vo, vol. 1, 1802; 36, 1813.

**Nuovo Cimento.** Il nuovo Cimento; giornale di Fisica, di Chimica, etc. Vol. 1–2, 1855–'56. 2d ser., vol. 1, 1869.

**Nyt. Mag.** See p. l.

**Phil. Mag.** Philosophical Magazine. 8vo, London. 1st ser. by Tilloch, 2 or 3 vols. a year; 1, 2, 1798; 3–5, '99; 6–8, 1800; 21–23, '05; 30–32, '08; 33, 34, '09 (thence 2 v. ann.); 35, 36, '10; 45, 46, '15; 55, 56, '20; 65, 66, '25; 67, 68, '26.

2d ser., or Philosophical Magazine and Annals of Philosophy, 2 v. ann.; 1, 2, 1827; 11, '32.

3d ser., London & Edinburgh Phil. Mag.; 1, 1832; 2, 3, '33; 12, 13, '38; 22, 23, '43; 32, 33, '48; 36, 37, '50.

4th ser., L., E. & Dublin Phil. Mag., 1, 2, 1851; 11, 12, '56; 21, 22, '61; 31, 32, '66; 49, 50, '75.

5th ser. with 1876. 1, 2, '76; 11, 12, '81; 21, 22, '86; 31, 32, '91.

**Pogg.** or **Pogg. Ann.** Annalen der Physik und Chemie; edited by J. C. Poggendorff. 8vo, Leipzig, 3 vols. ann. Preceded by Gilbert's Annalen (q.v.). Vols. 1, 2, 1824; 3–5, '25; 11, Index vol ; 18–20, '30; 27–29. '33; 30, Index vol.; 31–33, '34; 34–36, '35; 49–51, '40; 63–66, '45; 79–81, '50; 94–96, '55; 109–111, '60; 124–126, '65; 139–141, '70; 157–159, '76; last vol., 160, '77 Also Ergänzungsbd (Erg.), 1, 2, '48; 3, '53; 4, '54; 5, '71; 6, 7, '76; 8, '78, and Jubelband, 1874. General Index (Sachregister) to the whole series, 1824–1877, issued in 1888

Edited since 1877 by G. Wiedemann and called Wiedemann's Annalen; see **Wied. Ann.**

**Q. J. Sc.** Brandes' Quarterly Journal of Science. 8vo. 2 vols. ann. after 1819. Published by the Royal Institution. Vol. 1, 1816; 2, 3, '17, '17–'18; 4, 5, '18; 6, 7, 8, '19; 9, 10, '20; 19, 20, '25; 27, 28, '29.

**Rec. Gen. Sc.** Records of General Science; by Thos. Thomson. 4 vols., 8vo, Edinburgh. Vols. 1, 2, 1835; 3, 4, '36.

**Revista Minera.** Revista Minera, Periodico cientifico é industrial redactado por una Sociedad de Ingenieros. 2 vols., 8vo, Madrid. Vol. 1, 1850; 2, '51.

**Riv. Min.** Rivista di Mineralogia e Cristallografia Italiana diretta da R. Panebianco. Padua. Begun in 1887. Vol. 1, 1887; 8, 9, 1891.

**Scherer's J.** Allgemeines Journal der Chemie; conducted by A. N. Scherer. 10 vols., Leipzig und Berlin; 1, 1798; 2, 3, 1799; 6, 7, 1801; 10, '03. Continued as Gehlen's Journal (q.v.).

**Schw. J.** or **Schweigg. J.** Journal für Chemie und Physik; conducted by J. S. C. Schweigger. Nürnberg, 8vo. Also under the title Jahrbuch der Chemie und Physik. 3 vols. a year; 1–3, 1811; 16–18, '16; 28–30, '20; afterward issued by Schweigger & Meinecke; then by J.

S. C. Schweigger & Fr. W. Schweigger-Seidel; then by Fr. W. Schweigger-Seidel; 31–33, 1821; 46–48, '26; 61–63, '31; 67–69, '33 The next year began the J. pr. Ch. (q.v.), by Erdmann & Schweigger-Seidel.

**Science.** An illustrated Journal published weekly. Begun Feb. 1883, Cambridge, Mass. Vol. 1, Feb.–June '83; 6, July–Dec. '85, New York.

**Tasch. Min.** Taschenbuch für die gesammte Mineralogie, von C. C. Leonhard. 18 vols., 12mo, Frankfurt a. M., 1 vol. ann. Vol. 1, 1807; 4, '10, 9, '15, ~~14, '20;~~ 18, '24.

**Tschermak's Mitth.** See **Min. Mitth.**

**Wied. Ann.** Annalen der Physik und Chemie herausgegeben von G. Wiedemann, successor to Poggendorff, Annalen (see Pogg. Ann.), begun in 1877; 3 vols. ann. Vol. 1, 2, '77; 3–5, '78; 24–26, '85; 42–44, '91.

Also. connected with this, Beiblätter zu den Annalen der Physik und Chemie, begun in 1877, 1 vol. ann. Vol. 1, '77; 9, '85; 15, '91.

**Zs. Kr.** Zeitschrift für Krystallographie und Mineralogie, herausgegeben von Paul Groth, Leipzig. Begun in 1877; vol. 19 closed in 1891. Index to vols. 1–10, 1886 (Repertorium der mineral. u. kryst. Literatur, 1877–1885).

### 2. TRANSACTIONS, ETC., OF SCIENTIFIC SOCIETIES.

**Abh. Ak. Berlin.** Abhandlungen der königlichen preuss. Akademie der Wissenschaften zu Berlin. 4to, Berlin. Vol. 1 (for 1804–1811) issued in 1815.

**Abhandl. Senck. Ges. Frankfurt.** Abhandlungen von d. Senckenbergischen naturforschenden Gesellschaft zu Frankfurt. Begun in 1854. Vol. 7 in 1868; 16, '90.

**Act. Soc. Fenn.** Acta Societatis scientiarum Fennicæ. Helsingfors, Finland. Begun in 1842; 2–10, '47–'75.

**Ak. H. Stockholm.** K. Vet.-Akademiens Handlingar, Stockholm.

**Ak. H. Stockh., Bihang.** See **Ofv. Ak. Stockh.**

**Amer. Assoc.** Proceedings of the American Association for the Advancement of Science. 8vo. Vol. 1, meeting at Philadelphia in 1848; 2, at Cambridge in '49; 3, at Charleston in '50; 4, at N. Haven, '50; 5, at Cincinnati, '51; 6, at Albany, '52; 7, at Cleveland, '53; 8, at Washington, '54; 9, at Providence, '55; 10, at Albany, '56; 11, at Montreal, '57; 12, at Baltimore, '58; 13, at Springfield, '59; 14, at Newport, '60; 15, at Buffalo, '66; 16, at Burlington, '67; and annually since then, 40, at Washington, '91.

**Ann. Lyc. N. Hist. N. Y.** Annals of the Lyceum of Natural History of New York. Begun in 1824. Followed by the Annals of the New York Academy of Science. Vol. 1, 1879; 2, '82; etc.

**Ann. Mus. Wien.** Annalen des K. K. naturhistorischen Hofmuseums, redigirt von Dr. Franz Ritter von Hauer, Vienna. Begun in 1886; one vol. annually; vol. 6, 1891.

**Ann. Soc. G. Belg.** Annales de la Société géologique de Belgique. Vol. 1, '74–'75; 16, '89.

**Anzeig. Ak. Wien.** Anzeiger der K. K. Akad. d. Wissenschaften. 8vo, Vienna. Begun in 1864. 1 vol. ann.

**Att. Acc. Linc.** Atti della R. Accademia dei Lincei. Memoires, 3d ser., vol. 1, 1876–77; vol. 19, 1884. 4th ser., vol. 1, 1884–85. Transiunti, 3d ser., vol. 1, 1876–77; 8, '83. Followed by ser. 4, Rendiconti, vol. 1, 1884–85; vol. 7, '91.

**Att. Acc. Torino.** Atti della Reale Accademia delle Scienze. Turin, vol. 1, 1866; 26, '90–'91.

**Att. Ist. Veneto.** Atti delle Adunanze dell' R. Istituto Veneto di Scienze, Lettere ed Arti. Begun in 1840–41; 2d ser., 1850; 3d ser., 1855–56; 4th ser., 1871–72; 5th ser., 1874–75; 6th ser., 1882–83.

**Att. Soc. Tosc.** Atti della Societa Toscana di Scienze Naturali Pisa. Begun in 1875.

**Ber. Ak. Berlin.** Monatsberichte der. K. preuss. Akad. der Wissenschaften zu Berlin. 8vo Begun in 1836.

**Ber. Ak. München.** Sitzungsberichte der K. bayerischen Akad. der Wiss. zu München (Munich). 8vo. Begun in 1860. Since 1871 the volumes "der mathematisch-physikalischen Classe" numbered consecutively. Vol. 1, 1871; 10, '80; 20, '90.

**Ber. Ak. Wien.** Sitzungsberichte der K. Akad. der Wiss., Wien (Vienna). Commenced in 1848, 8vo. Vol. 1, '48; 10, 11, '53; 12–14, '54; 15–18, '55; 39–42, '60. From '61 in two sections, 2 vols. each; 51, 52, '65; 61, 62, '70. From '72 in three sections, and '88, 4 sections. Vols. 98, 99, '90. General Index to vols. 1–10, 11–50, 51–60, 61–64, 65–75, 76–80, 81–85, 86–90, 91–96.

**Ber. aus Ungarn.** Mathematische und Naturwissenschaftliche Berichte aus Ungarn. Begun in 1882. Vol. 1, Oct. '82 to June '83 There is also a publication called "Literarische Berichte aus Ungarn."

**Ber. Ch. Ges.** Berichte der deutschen chemischen Gesellschaft, Berlin. Begun in 1868, vol. 1, '68; 5, '72; 24, '90. General Index 1868–77.

**Ber. nied. Ges.** Sitzungsberichte der niederrheinischen Gesellschaft in Bonn. Issued in the same volume with **Vh. Ver. Rheinl.** (q.v.).

**Ber. Sächs. Ges. Leipzig.** Berichte der K. Sächs. Gesellschaft der Wiss., Leipzig.

**Boll. Com. G.** R. Comitato Geologico d' Italia, Bolletino. Commenced in 1869, published in yearly volumes of 12 numbers. Vol. 22, 1891.

**Bull. Ac. Belg.** Bulletin de la Académie Royale de Belgique. Vol. 1, '32–'34. 2d ser., 1, 2, '57; 49, 50, '80. 3d ser., 1, 2, '81; 21, 22, '91.

**Bull. Ac. St. Pet.** Bulletin scientifique de l'Acad. Impériale des Sciences de St. Pétersb. 4to, St. Petersburg. Vol. 1, 1858; 10, 1867; 32, 8vo, '88; vol. 1 (33) of a new series (8vo) in 1890. Preceded by the two Bulletins, B. physico-mathématique, 17 vols. 4to, and B. historico-philologique, 16 vols. 4to; and these two preceded by the one Bull. Scientifique, 10 vols. 4to.

**Bull. Mus. Belg.** Bulletin du Musée Royal d'Histoire Naturelle de Belgique. Brussels. Vol. 1, 1882.

**Bull. Soc. Ch.** Bulletin mensuel de la Société Chimique de Paris. 8vo, 1 vol. ann. 1st ser., 1857–64. 2d ser., vol. 1, 2, '64; 15, 16, '71; 35, 36, '81; 49, 50, '88. 3d ser., vol. 1, 2, '89; 5, 6, '90.

**Bull. Soc. G.** Bulletin de la Société Géologique de France. 8vo, Paris. 1st ser., vol. 1, 1830–31; 2, '31–'32; 3, '32–'33; 4, '33–'34; 5, '34; 6, '34–'35; 7, '35–'36; 12, '40–'41; 14, '42–'43. 2d ser., vol. 1, '43–'44; 6, '48–'49; 11, '53–'54; 16, '58–'59; 21, '63–'64; 26, '68–'69; 29, '71–'72. 3d ser., vol. 1, '72–'73; 15, '86–'87, etc.

**Bull. Soc. Imp. Nat. Moscou.** Bulletin de la Soc. Impériale des Naturalistes de Moscou. 8vo.

**Bull. Soc. Min.** Bulletin de la Société Minéralogique de France, Paris. Begun in 1878, 1 vol. annually; vol. 14, 1891; also Index to vols. 1–10, 1888. Since 1886 the title has been, La Société Française de Minéralogie.

**C. R.** Comptes Rendus des Séances de l'Académie des Sciences. 4to, 2 vols. ann.; vol. 1, 1835; 2, 3, '36; 12, 13, '41; 22, 23, '46; 32, 33, '51; 42, 43, '56; 52, 53, '61; 62, 63, '66; 72, 73, '71; 82, 83, '76; 92, 93, '81; 102, 103, '86; 112, 113, '91. General Index vols. 1–31, 32–61.

**Denkschr. Ak. Wien.** Denkschriften der kais. Akademie d. Wiss. in Wien; Math.-Naturwiss. Classe. 4to, Wien. Begun in 1850; vol. 25 in 1866; 57, '90.

**Földt. Közl.** Földtani Közlöny (Geologische Mittheilungen), Zeitschrift der ungarischen geologischen Gesellschaft, zugleich amtliches Organ der K. Ung. geol. Anstalt. 8vo, Budapest. Begun in 1872; vol. 21, 1891.

**Forh. Vid. Selsk. Christiania.** Forhandlinger i Videnskabs-Selskabet i Christiania. 8vo.

**G. För. Förh.** Geologiska Föreningens i Stockholm Förhandlingar, Stockholm. Begun in 1872; vol. 1, 1872–74; vol. 7, 1884–85. Since 1885 one vol. annually; vol. 13, '91. Index vols., 1–5, '82; 6–10, '90.

**Gel. Anz. Münch.** Gelehrte Anzeige der K. bayerischen Akad. der. Wiss. zu München. 4to. Vol. 1, 1835; 39, '54.

**Haid. Ber.** Berichte über die Mittheilungen von Freunden der Wiss. in Wien; edited by W. Haidinger. 8vo, 7 vols., 1846–51.

**J. Ac. Philad.** Journal of the Academy of Natural Sciences of Philadelphia. 1st ser., 8vo, 7 vols., 1817–42. 2d ser., 4to, begun in 1847.

**J. Ch. Soc.** Journal of the Chemical Society. 1st ser., called Quarterly Journal, etc. 15 vols.; one vol. (of 4 Nos.) a year; vol. 1, 1849; 6, '54; 11, '59; 15, '63. 2d ser., monthly, begun in 1864, the vols., however, generally numbered from the beginning; vol. 28, '75; since 1876 2 vols. annually, and beginning with '79 the transactions and abstracts separated. Vols. 29, 30, '76; 59, 60, '91.

**J. Coll. Sc. Japan.** Journal of the College of Science, Imperial University of Japan. 4to. Tōkyō. Begun in 1888.

**J. Frankl. Inst.** Journal of the Franklin Institute of the State of Pennsylvania, etc. Vol. 1, 2, 1826; 131, 132, '91.

**J. Nat. Hist. Bost.** Boston Journal of Natural History. 8vo, 7 vols., 1834–63.

**Jb. G. Reichs.** Jahrbuch der kaiserlich-königlichen geologischen Reichsanstalt, Wien. Begun in 1850, 1 vol. ann. Vol. 1, 1850; 11, '60; 12, '61–'62; 20, '70; 30, '80; 41, '91. General Index to vols. 1–10, '63; 11–20, '72; 21–30 (also '71–'80 of Vh. G. Reichs.), '81.

**Jb. Wett. Ges. Hanau.** Jahresbericht der wetterau'schen Gesellschaft für die gesammte Naturkunde. 8vo, Hanau, 1850–53.

**Mag. Ges. nat. Fr. Berlin.** Magazin der Gesellschaft naturforschender Freunde. 8 vols. 4to; 1, 1807; 2, '08; 3, '09; 4, '10; 5, '11; 6, '14; 7, '16; 8, '18. Afterward Verhandl. ib.

**Mem. Acc. Torino.** Memorie della reale Accademia delle Scienze di Torino. 4to, Turin; 1st ser. 40 vols., 1815,–'38; 2d ser. begun in 1839, and vol. 22 in '65.

**Mem. Am. Ac. Bost.** Memoirs of the American Academy of Arts and Sciences. 4to, Boston.

**Mem. Wern. Soc.** Memoirs of the Wernerian Society of Natural History. 8vo, Edinburgh. Vols. 1–8, 1808–38.

**Min. Mag.** Mineralogical Magazine and Journal of the Mineralogical Society of Great Britain and Ireland. London and Truro. Begun in 1877. Vol. 1, 1877; vol. 9, 1890–91.

**Nyt. Mag.** Nyt Magazin for Naturvidenskaberne; udgives (grundlaget) af den physiographiske Forening i Christiania. 8vo, Christiania. Begun in 1838; vols. 1, 2, '38–'40; 29 30, '85–'86.

**Öfv. Ak. Stockh.** Öfversigt af K. Vet.-Akad. Förhandlingar, Stockholm. Commenced in 1844. 1 vol. ann., 8vo; vol. 48, '91. Also a series of supplementary volumes. Bihang till K. Svenska Vetenskaps-Akademiens Förhandlingar, vol. 1, 1873; vol. 13, 1888, etc.

**Overs. Vid. Selsk. Copenh.** Oversigt over det Kongelige danske Videnskabernes Selskabs Forhandlinger. Copenhagen, 8vo.

**Phil. Trans.** Transactions of the Royal Society of London. 4to. Vol. 1 contains transactions for 1665, '66. Vol. 182. '91.

**Phys. Arb. Fr. Wien.** Physikalische Arbeiten der einträchtigen Freunde in Wien; published in Quartals; 1 qu., 1783; 2 qu., '84; 3, 4 qu., '85. 2d vol., 1 qu., '86; 2 qu., '87; 3 qu., '88.

**Proc. Ac. Philad.** Proceedings of the Acad. Nat. Sci., Philadelphia. 8vo. Begun in 1841.

**Proc. Am. Acad.** Proceedings of the American Academy of Acts and Sciences. 8vo, Boston. Begun in 1846; vol. 25, '90.

**Proc. Am. Assoc.** See **Am. Assoc.**

**Proc. Am. Phil. Soc.** Proceedings of the American Philosophical Society, Philadelphia. Vol. 29, '91.

**Proc. Col. Soc.** Proceedings of the Colorado Scientific Society, Denver, Colorado. Begun in 1883; 3 vols. completed.

**Proc. Cryst. Soc.** Proceedings of the Crystallological Society. 8vo, London. Part I. 1877; II, 1882.

**Proc. N. Hist. Soc. Bost.** Proceedings of the Nat. Hist. Society of Boston. 8vo. Begun in 1841.

**Proc. Roy. Soc.** Proceedings of the Royal Society of London. 8vo. (Abstracts of paper presented, etc.) Vol. 1, 1800–'14; 2, '15–'30; 35, '30–'37; 4, '37–'43; 5, '43–'50; 10, '59–'60; 20, '71–'72; 30, '79–'80; 47, '89–'90; 48, '90; 49–50, '90–'91; 51, '92.

**Proc. Roy. Soc. Edinb.** Proceedings of the R. Soc. of Edinburgh. 8vo.

**Q. J. Ch. Soc.** See **J. Ch. Soc.**

**Q. J. G. Soc.** Quarterly Journal of the Geological Society. 8vo, London. Begun in 1845; 1 vol. ann.; vol. 47, '91.

**Rec. G. Surv. India.** Records of the Geological Survey of India. 8vo, Calcutta. Begun in 1868; vol. 20, '87 (Index vols. 1–20); 24, '91.

**Rep. Brit. Assoc.** Reports of the British Association for the Advancement of Science. Begun in 1831; 61st meeting at Cardiff, '91.

**Sch. Mines Q.** The School of Mines Quarterly, Columbia College, New York. Begun in 1880.

**Schrift. Ges. nat. Fr. Berlin.** Schriften der Gesellschaft naturforschender Freunde in Berlin. 11 vols 8vo, the first 1 v. ann.; 1, 1780; 5, '84; 8, '86–'87; 8, '88; 9, '89; 10, '92; 11, '94 (vols. 7–11, also as 1–5 of Beobachtungen und Entdeckungen, etc.). Next, Neue Schriften, etc., 4 vols. 4to; 1, 1795; 2, '99; 3, 1801; 4, 1803–4. Afterward Magazin, etc. (q.v.).

**Schriften Min. Ges. St. Pet.** Schriften der russisch-kaiserlichen Gesellschaft für die gesammte Mineralogie. 1842. For continuation see **Vh. Min. Ges.**

**Tech. Q.** Technological Quarterly (published by the Institute of Technology). Boston. Begun in 1887.

**Trans. Am. Phil. Soc.** Transactions of the American Philosophical Society. 4to, Philadelphia.

**Trans. Roy. Soc. Edinb.** Transactions of the Royal Society of Edinburgh. 4to.

**Vh. G. Reichs.** Verhandlungen der kaiserlich-königlichen geologischen Reichsanstalt. Vienna. Begun in 1867.

**Vh. Min. Ges.** Verhandlungen d. russisch-kaiserlichen mineralogischen Gesellschaft zu St. Petersburg. 1st ser., 1842–58. 2d ser., vol. 1, 1866; 26, 1890.

**Vh. nat. Ges. Basel.** Verhandlungen der naturforschenden Gesellschaft in Basel. Begun in 1854.

**Vh. Ver. Rheinl.** Verhandlungen des naturhistorischen Vereines der preussischen Rheinlande und Westphalens. Published at Bonn. Begun in 1844. Vol. 10, '53; 20, '63; 30, '73; 40, '83; 48, '91. Index 1–40, '44–'83.

**Zs. G. Ges.** Zeitschrift der deutschen geol. Gesellschaft. 8vo, Berlin; a quarterly; 1 vol. ann., Vol. 1, 1849; 11, '59; 21, '69; 31, '79; 41, '89; 43, '91.

**Zs. Nat. Halle, or Zs. Ver. Halle.** Zeitschrift für die gesammten Naturwissenschaften, von dem nat. Verein f. Sachsen und Thüringen in Halle. Begun in 1853. Vol. 63, 1890. Since 1883, vol. 56, the title has been Zeitschrift für Naturwissenschaften, etc.

## 3. INDEPENDENT WORKS.

**Achiardi, I Metalli.** I Metalli loro Minerali e Miniere, by A. D'Achiardi. Vol. 1, 402 pp. 8vo; vol. 2, 635 pp. Milan, 1883.

**Achiardi, Min. Tosc.** Mineralogia della Toscana, by A. D'Achiardi. Vol. 1, 276 pp., 1872; vol. 2, 402 pp. 8vo, Pisa, 1873.

**Adam, Tabl. Min.** Tableau Minéralogique, by M. Adam. 102 pp. 4to, Paris, 1869.

**Agric., Ort. Caus. Subt.** Georgius Agricola, de Ortu et Causis subterraneorum; preface dated 1543.

**Agric., Foss.** Id., de natura fossilium; pref. dated 1546; and De veteribus et novis metallis; pref., 1546.

**Agric., Berm.** Bermannus, sive De re metallica Diallogus; pref., 1529.

**Agric., Interpr.** Interpretatio Germanica vocum rei metallicæ; pref., 1546. The edition of Agricola's works, cited beyond, including the four preceding parts, is one in folio. 1 vol., Basileæ (Basel), 1558.

**Agric., Metall.** De re Metallica; by id. Preface dated 1550. Fol., Basileæ, 1557.

**Aikin, Min.** Manual of Mineralogy; by A. Aikin. 2d ed., 8vo, London, 1815. The 1st ed. appeared in 1814.

**Albert. Magnus, Min.** Albertus Magnus, De Mineralibus. Written after 1262.

**Alger-Phillips Min.** Treatise on Min. by Wm. Phillips; 5th ed. (from the 4th London ed. by R. Allan), with numerous additions by F. Alger. 8vo, Boston, 1844.

**Allan, Min.** Manual of Mineralogy; by R. Allan. 8vo, Edinburgh, 1834. See also **Phillips.**

**Allan, Min. Nomencl.** Mineralogical Nomenclature; by T. Allan. 8vo, Edinburgh, 1814.

**Argenville, Oryct.** L'Histoire Naturelle, etc.; by D. d'Argenville. 4to, Paris, 1755.

**Aristotle.** Aristotle's works; particularly the *Μετεωρολογικὰ*, or "Meteorology," and *Περὶ Θαυμασίων ακουσμάτων*, or "Wonderful Things Heard of." Works written about the middle of the 4th century B.C. A. born about 384 B.C. and d. 322 B.C.

**Arppe, Finsk. Min.** Analyser af Finska Mineralier; by A. E. Arppe. Part I, 1855, from the Act. Soc. Fenn., **4,** 561–578; II, 1857, ib., **5,** 467 (paged 1–51); III, 1859–1861, ib., **6,** 580.

**B. de Boot.** Lap. Gemmarum et Lapidum Historia. 4to, Jena, 1647; the 1st edit. published at Jena in 1609; the 2d, enlarged by A. Toll, Lugduni Bat., 8vo, 1636.

**Ball, Geol. India.** A Manual of the Geology of India. Part III. Economic Geology; by V. Ball, 640 pp. Calcutta, 1881.

**Bauer, Min.** Lehrbuch der Mineralogie von Max Bauer. 562 pp. 8vo, Berlin and Leipzig, 1886.

**Bauerman, Min.** Text-Book of Systematic Mineralogy; by Hilary Bauerman. 367 pp. 12mo, London, 1881.

Text-Book of Descriptive Mineralogy; by id. 399 pp., London, 1884.

**Baumh., Kryst.** Das Reich der Krystalle für jeden Freund der Natur, insbesondere für Mineraliensammler, leichtfasslich dargestellt; by H. Baumhauer. 364 pp. 8vo, Leipzig, 1889.

**Beck, Min. N. Y.** See **Rep. Min. N. Y.,** beyond.

**Bergm., Opusc.** Opuscula of Torbernus Bergmann. 1780.

**Bergm., Sciagr.** Sciagraphia Regni Mineralis (in Latin); by T. Bergmann. 8vo, 1782; reprint in London, 1783.

**Berz., N. Syst. Min.** Neues System der Mineralogie; translated from the Swedish by Drs. Gmelin and Pfaff. Nürnberg, 1816.

Nouveau Système de Minéralogie; by J. J. Berzelius. 8vo, Paris, 1819; translated from the Swedish.

**Berz., Löthr.** Die Anwendung des Löthrohrs, etc. Germ. Transl. by H. Rose. Nürnberg, 1821; 4th ed., 1844. American ed. by Whitney, 1846.

**Beud., Tr., 1824, 1832.** Traite élémentaire de Min.; by F. S. Beudant. 8vo, Paris, 1824; 2d ed., 2 vols., 1832.

**Bischoff, Ch. Geol.** Lehrbuch de chemischen und physikalischen Geologie; by G. Bischoff. 2 vols. 8vo. Bonn, 1847–54. 2d ed., 1863–66. Also an English edition.

**Blum, Min.** Lehrbuch der Mineralogie (Oryktognosie); by J. Reinhard Blum. I. Abth., 4th Ed., 256 pp. 8vo, Stuttgart, 1873; II. Abth., 257–642 pp., 1874.

**Blum, Pseud.** Die Pseudomorphosen des Mineralreichs; by J. R. Blum. Stuttgart, 1843. With Nachträge, 1, 1847; 2, Heidelberg, 1852; 3, Erlangen, 1863; 4. Heidelberg, 1879.

**Blumenbach, Handb.** Handbuch der Naturgeschichte. 8vo, 8th ed., Göttingen, 1807.

**Bombicci, Min.** Corso di Mineralogia, Seconda Edizione. 2 vols. (vol. 2 in two parts), 1873–75. Bologna.

**Boricky, Ch. Min.** Elemente einer neuen chemisch-mikroskopischen Mineral- und Gesteinsanalyse; by E. Boricky. 72 pp. 4to, Prag, 1877.

**Born, Brief. Wälschl.** Briefe aus Wälschland (Italy); by I. v. Born. 8vo, Prague, 1773.

**Born, Lithoph.** Lythophylacium Bornianum; Index Fossilium quæ colligit, etc., Ignatius S. R. I. Eques a Born. 2 parts, Prague; part 1, 1772; 2, '75. A descriptive catalogue, but without notes.

**Born, Cat. Foss. de Raab.** Catalogue méthodique et raisonné de la collection des Fossiles de Mlle. Eleonore de Raab; by id. 4 vols. 8vo, Vienna, 1790.

**Bourgeois, Reprod. Min.** Réproduction artificielle des Minéraux; by Léon Bourgeois. 240 pp. 8vo. Paris, 1884. (Encycl. Chimique by M. Frémy, vol. 2, 1st Appendix.)

**Bourn., Cat.** Catalogue de la Collection minéralogique particulière du Roi; by Comte de Bournon. 8vo, with Atlas in fol., Paris, 1817.

**Bourn., Min.** Traité de Minéralogie; by Comte de Bournon. 3 vols. 4to, 1808.

**Boutan, Diamant.** Le Diamant; by E. Boutan. 323 pp. 8vo, Paris, 1886. (Encycl. Chimique by M. Frémy.)

**Brackebusch, Min. Argentina.** Las Especies Minerales de la República Argentina; by D. Luis Brackebusch. 120 pp., Buenos Aires, 1879. (Anal. Soc. Cientif. Argentina.)

**Bravais, Crist.** Etudes Cristallographiques. Paris, 1866 (1849).

**Breith., Char. 1820.** Kurze Charakteristik des Mineral-Systems; by A. Breithaupt. 8vo, Freiberg, 1820.

**Breith., Char. 1823, 1832.** Vollständige Char., etc.; by id. 8vo, Dresden, 1823; 2d ed., 1832.

**Breith., Uib. 1830.** Übersicht des Mineral-System's; by A. Breithaupt. 8vo, Freiberg, 1830.

**Breith., Handb.** Vollständiges Handbuch der Mineralogie; by id. 8vo, Dresden and Leipzig; vol. 1, introduct., 1836; 2, '41; 3, '47.

**Brochant, Min.** Traité de Minéralogie; by A. J. M. Brochant. Paris, 1808; an earlier edition in 1800.

**Bromell, Min.** Herr Magni von Bromells Mineralogia. 2d ed., 16mo, Stockholm, 1739. 1st ed. pub'd in 1730.

**Brongn., Min.** Traité élémentaire de Minéralogie; by A. Brongniart. 2 vols. 8vo, Paris, 1807.

**Brongn., Tabl.** Tableau des Espèces Minérales; by id. 48 pp. 8vo, Paris, 1833.

**Brooke, Cryst.** Familiar Introduction to Crystallography; by H. J. Brooke. 8vo, London, 1823.

**B. & M., Min.** Introduction to Mineralogy, by the late Wm. Phillips; new edition, with extensive alterations and additions, by H. J. Brooke and W. H. Miller. 8vo, London, 1852. Prof. Miller is the author also of a Treatise on Crystallography, 8vo, Cambridge, 1839, giving the elements of the system adopted in the above work, a system first proposed by Whewell, in Phil.Trans. for 1825.

**Bruckmann, Magnalia Dei** in locis subterraneis. 2 parts, fol.; part 1, 1727; 2, '30.

**Brush, Determ. Min.** Manual of Determinative Mineralogy, with an Introduction on Blowpipe Analysis. 176 pp. 8vo, New York, 1875. 3d Ed. 104 pp., 1878.

**Buchner, Meteoriten.** Die Meteoriten in Sammlungen; ihre Geschichte, mineralogische und chemische Beschaffenheit; by Otto Buchner. 202 pp., Leipzig, 1863.

**Cæsius, Min.** De Mineralibus; by Bernardius Cæsius. 656 pp. fol., Lugduni, 1636.

**Cal. Min. Rep.** Annual Reports of the State Mineralogist of California. 1, June to Dec. 1880; 2, Dec. 1880 to Oct. 1882; 3, 1883; 4, 1884; 5, 1885; 6, in two parts, 1886–87; 7, 1887; 8, 1888; 9, 1889; 10, 1890.

**Cappeller, Crist.** Prodromus Cristallographiæ; Marc. Ant. Cappeller. 4to, Lucerne, 1723.

**Cat. de Drée.** Catalogue des huit Collections qui composent le Musée minéralogique de Et. de Drée. 4to, Paris, 1811. Dufrénoy speaks of it as the work of M. Leman.

**Chapman, Min.** Practical Mineralogy; by E. J. Chapman. 8vo, London, 1843.

**Chapman, Char. Min.** Brief Description of the Characters of Minerals; by id. 12mo, London, 1844

**Cleaveland, Min., 1816, 1822.** Treatise on Mineralogy and Geology. 8vo, Boston, 1816; 2d ed., 2 vols. 8vo, Boston, 1822.

**Cohen, Samml.** Sammlung von Mikrophotographieen zur Veranschaulichung der mikroskopischen Structur von Mineralien und Gesteinen, aufgenommen von J. Grimm, Offenburg; by E. Cohen. Lief. 1–8, Stuttgart, 1881–83.

**Cornwall, Blowpipe Anal.** Manual of Blowpipe Analysis, qualitative and quantitative, with a complete system of Determinative Mineralogy; by H. B. Cornwall. 308 pp. 8vo, New York, 1882.

**Cronst., or Cronst. Min., 1758, 1781.** Mineralogie; eller Mineral-Rikets Upstallning; by A. Cronstedt (but issued anonymously). 12mo, Stockholm, 1758; Brünnich's edit. in Danish, Copenhagen, 8vo, 1770; 2d Swedish ed., Stockholm, 1781; Magellan's edit in English, 2 vols. 8vo, London, 1788.

**Dana, Manual.** Manual of Mineralogy and Petrography, containing the elements of the Science of Minerals and Rocks for the use of the practical Mineralogist and Geologist and for instruction in Schools and Colleges; by James D. Dana. 4th edition, 517 pp. 12mo, New York, 1887. 1st ed., '50; 2d ed., '57; 3d ed., 1878.

**Dana, Min.** This work; by James D. Dana, 1837–1868. Edition 1, 1837; 2, 1844; 3, 1850; 4, 1854, with supplements 1 to 10 to 4th edition in the Am. J. Sc., 1855–1862, the last three by G. J. Brush; 5th ed., 1868, by James D. Dana aided by G. J. Brush, with appendix 1, 1872, by G. J. Brush; 2, 1875, and 3, 1882, both by E. S. Dana.

**Dana, Min. Boston.** Outlines of the Mineralogy and Geology of Boston and its vicinity; by J. Freeman and S. L. Dana. 8vo, Boston, 1818.

**Dana, Text-Book.** A Text-Book of Mineralogy, with an extended Treatise on Crystallography and Physical Mineralogy; by E. S. Dana, on the plan and with the co-operation of James D. Dana. 486 pp. 8vo, New York, 1877; 2d ed., 1883.

**Daubenton, Tabl.** Tableaux méthodiques des Minéraux. Paris, 1784. Only a classified catalogue. Several subsequent editions were issued, the 6th in 1799.

**Davila, Cab.** Catalogue syst. et raisonné des Curiosités de la Nature et de l'Art qui composent le Cabinet de M. Davila. 3 vols. 8vo, Paris, 1767.

**Dechen, Nutzb. Min.** Die nutzbaren Mineralien und Gebirgsarten im deutschen Reiche; by H. von Dechen. 806 pp. 12mo, Berlin, 1873.

**Delameth., Sciagr.** New edition of Mongez's Sciagraphie (Fr. trl. of Bergmann's Sciagr., with additions); by J. C. Delamétherie. 2 vols. 8vo, Paris, 1792.

**Delameth., T. T.** Théorie de la Terre; by id. 2d ed., 5 vols., Paris, 1797; vols. 1, 2, of this edition contain his Mineralogy.

**Delameth., Min.** Leçons de Minéralogie; by id. 8vo, vol. 1, 1811; 2, '12, Paris.

**De Lisle, Crist., 1772.** Essai de Cristallographie; by Romé de l'Isle. 8vo, Paris, 1772.

**De Lisle, Crist., 1783.** Cristallographie, ou Description des formes propres à tous les corps du Regne minéral; by id. Called 2d edition of the preceding. 4 vols. 8vo, Paris, 1783.

**Demeste, Lettres.** Lettres sur la Minéralogie; by Dr. Demeste. 2 vols. 16mo, 1779.

**Dioscor.** Dioscorides *Περί ὕλης ἰατρικῆς* (Materia Medica), written about A.D. 50. In the mineral part treats especially of the medical virtues of minerals, but often gives also short descriptions. Not alluded to among the many references in Pliny, but evidently cited from.

**Doelter, Allg. Ch. Min.** Allgemeine chemische Mineralogie; by C. Doelter. 277 pp. 8vo, Leipzig, 1890.

**Domeyko, Min., 1845, 1860, 1883.** Elementos de Mineralojia; by I. Domeyko. 8vo, Chili, 1st ed.; Serena, 1845. 2d ed., Santiago, 1860, with appendixes 1–6. 3d ed., 762 pp., 1879; also appendix 1, 1881; 2, 1883.

**Domeyko, Tratado de Ensayes**; by id. 2d ed., 8vo, Valparaiso, 1858.

**Dufr., Min., 1844, 1856–1860.** Traité de Minéralogie; by A. Dufrénoy. 4 vols. 8vo (the last of plates), Paris, 1844; 2d ed., 5 vols.; 1, 2, 3, '56; 4, '59; 5, '60.

**Dx., Min.** Manuel de Minéralogie; by A. Des Cloizeaux. 572 pp., with 52 plates, 8vo, Paris, vol. 1, 1862; vol. 2, 1er Fasc., 208 pp., Paris, 1874.

**Dx., N. R.** Nouvelles Recherches sur les Propriétés optiques des Cristaux, naturels ou artificiels, et sur les variations que ces propriétés éprouvent sous l'influence de la chaleur; by id. 222 pp. 4to, Paris, 1867. (Mémoires présent. à l'Institut impérial de France, vol. 18.)

**Dx., Proptr. Opt. 1, 2.** De l'emploi des propriétés optiques biréfringentes en Minéralogie; by id. 1, 1857 (Ann. Mines, vol. 11, pp. 261–342). Also 2 (2e Mémoire); by id., 1858 (ibid., vol. 14, pp. 339–420). The *third* memoir of this series is given in **N. R.** above. Still another with description of instruments, methods, etc., was published in 1864—Mémoire su l'emploi du microscope polarisant, etc. (ibid., vol. 6. 557–595, 1864).

**Dx., Quartz.** Mémoire sur la Cristallisation et la Structure intérieure du Quartz; by A. Des Cloizeaux. 212 pp. 4to, with 5 folded plates, Paris, 1858.

**Egleston, Min. Syn.** Catalogue of Minerals and Synonyms alphabetically arranged, 1889 (Bull. U. S. Nat. Mus., No. 33); by Thomas Egleston. Also republished, enlarged. 378 pp., New York, 1891.

**Emmerling, Min.** Lehrbuch der Mineralogie; by L. A. Emmerling. 8vo, Giessen, 1st ed., 1793–'97; 2d ed., '99, 1802.

**Ercker, Aula Subt.** Aula Subterranea (on Ores, Mining, and Metallurgy); by L. Ercker. Written in 1574, published in 1595.

**Erdmann, Dannemora Jernm.** Dannemora Jernmalmsfält, etc.; by A. Erdmann. 12mo, Stockholm, 1851. Also Utö Jernm., 1856.

**Erdmann, Min.** Lärobok i Mineralogien; by A. Erdmann. 8vo, Stockholm, 1853.

**Estner, Min.** Versuch einer Mineralogie. 3 vols. in 5 parts, 8vo, Vienna, 1794–1804.

**Estner, über Werner's Verbess. in Min.** Freymüthige Gedanken über Herrn Inspector Werner's Verbesserungen in der Mineralogie, nebst einigen Bemerkungen über Herrn Assessor Karstens Beschreibung des vom sel. Leske Mineralien-Cabinetts; by Abbe Estner. 64 pp. 18mo, Wien, 1790.

**Exner, Unt. Härt.** Untersuchungen über die Härte der Krystallflächen; by Franz Exner. 166 pp. 8vo, Vienna, 1873.

**Fabricius, Met.** De rebus metallicis ac nominibus observationes variæ, etc., ex schedis Georgii Fabricii. Tiguri, 1566. Issued with an edition of Gesner's Foss.

**Faujas, Volc. Viv.** Recherches sur les Volcans éteints du Vivarais et du Velay; by Faujas de St. Fond. Fol., Grenoble et Paris, 1778. By the same, Minéralogie des Volcans, 8vo, Paris, 1784.

**Fischer, Mikr. Min.** Kritische mikroskopisch-mineralogische Studien; by H. Fischer. 64 pp. 8vo, Freiburg i. Br., 1869. Erste Fortsetzung, 64 pp., 1871. Zweite Fortsetzung, 96 pp., 1873.

**Fischer, Nephrit.** Nephrit und Jadeit nach ihren mineralogischen Eigenschaften, so wie nach ihrer urgeschichtlichen und ethnographischen Bedeutung; by Heinrich Fischer. 411 pp. 8vo, Stuttgart, 1875; 2te Auflage, 1880.

**Fors., Min.** Minerographia; by Sigfrid Avon Forsius. 16mo, Stockholm, 1643.

**Fouqué-Lévy, Min. Micr.** Minéralogie micrographique, roches éruptives Françaises; by F. Fouqué and A. Michel-Lévy. 509 pp. 4to. Paris, 1879.

**Fouque-Lévy, Synth. Min.** Synthèse des Minéraux et des roches; by F. Fouqué and Michel-Lévy. 423 pp. 8vo, Paris, 1882.

**Frenzel, Min. Lex.** Mineralogisches Lexicon für das Königreich Sachsen; by August Frenzel. 380 pp. 12mo, Leipzig, 1874.

**Fuchs, Künst. Min.** Die künstlich dargestellten Mineralien, etc.; by Dr. C. W. C. Fuchs. 174 pp. 8vo, Haarlem, 1872 (Nat. Verhandelingen).

**Gallitzin, Dict. Min.** Recueil de noms par order alphabétique apropriés en Minéralogie; by D. de Gallitzin. Sm. 4to, Brunswick, 1801.

**Gdt., Index.** Index der Krystallformen der Mineralien; by Dr. Victor Goldschmidt. 3 vols., 1886–1891, Berlin.

**Gesner, Foss.** De omni rerum fossilium genere, Gemmis, Lapidibus, Metallis, etc.; opera Conradi Gesneri. Tiguri, 1565.

**Genth, Min. N. C.** The Minerals of North Carolina. Bulletin of the U. S. G. Surv., No. 74. 119 pp., Washington, 1891. Also earlier, Minerals and Mineral Localities of North Carolina. 122 pp., Raleigh, 1881 (Geol. N. Carolina, 1881).

**Genth, Min. Rep. Penn.** Preliminary Report on the Mineralogy of Pennsylvania; by F. A. Genth, with an appendix on the Hydrocarbon Compounds by S. P. Sadtler. 206 pp., 1875 (2d G. Surv. Penn., 1874). Second Preliminary Report; 31 pp., Harrisburg, 1876.

**Geol. India.** See **Ball. Geol. India.**

**Geol. Rec.** The Geological Record for 1874: an account of works on Geology, Mineralogy, and Palæontology published during the year; edited by W. Whitaker, London, 1875. Also similar volumes for 1875, 1876, 1877, 1878, 1879; for 1880–84 in two volumes.

**Geol. Rev.** Revue de Géologie pour l'année 1860; by M. Delesse and M. Laugel. Vol. 16 for 1877–78.

**Glocker, Handb., 1831, 1839.** Handbuch der Mineralogie; by E. F. Glocker. 8vo, Nürnberg, 1831; 2d edit., 1839.

**Glocker, Syn.** Generum et Specierum Mineralium secundum Ordines Naturales digestorum Synopsis; by id. 8vo, Halle, 1847.

**Gmelin, Min.** Einleitung in die Mineralogie; by J. F. Gmelin. 8vo, Nürnberg, 1780. By the same, Grundriss einer Min. 8vo, Göttingen, 1790.

**Greg & Lettsom, Min.** Manual of the Mineralogy of Great Britain and Ireland; by R. P. Greg and W. G. Lettsom. 8vo, London, 1858.

**Gurlt, Künstl. Min.** Uebersicht der pyrogenneten künstlichen Mineralien, namentlich der krystallisirten Hüttenerzeugnisse; by Dr. A. Gurlt. 8vo, Freiberg, 1857.

**Groth, Edelsteinkunde.** Grundriss der Edelsteinkunde; by Paul Groth. 165 pp. 8vo, Leipzig, 1887.

**Groth, Min.-Samml.** Die Mineralien-Sammlung der Kaiser-Wilhelms-Universität, Strassburg; ein Supplement zu den vorhandenen mineralogischen Handbüchern; by Paul Groth. 271 pp. 4to, Strassburg, 1878.

**Groth, Phys. Kryst.** Physikalische Krystallographie und Einleitung in die krystallographische Kenntniss der wichtigeren Substanzen; by Paul Groth. 523 pp. 8vo, Leipzig, 1876. 2d ed., 710 pp., 1885.

**Groth, Tab. Ueb.** Tabellarische Uebersicht der Mineralien nach ihren krystallographisch-chemischen Beziehungen geordnet; by id. 120 pp. 8vo, Braunschweig, 1874. 2d ed., 134 pp. 4to, 1882. 3d ed., 167 pp. 4to, 1889.

**H., Tr., 1801, 1822.** Traité de Minéralogie; by C. Haüy. A 4to ed. of 4 vols., with atlas in fol.; also an 8vo ed., Paris, 1801; 2d ed., 4 vols. 8vo, with fol. atlas, 1822.

**H., Crist.** Traité de Cristallographie; by id. 2 vols. 8vo, 1822.

**H., Tabl. Comp.** Tableau Comparatif des résultats de la Cristallographie et de l'analyse chimique relativement à la classification des Minéraux; by id. 8vo, Paris, 1809.

**Haid., Min. Mohs.** Treatise on Mineralogy, by F. Mohs; trl., with considerable additions, by Wm. Haidinger. 3 vols. 8vo, Edinburgh, 1825.

**Haid., Min.** Anfangsgründe d. Min.; by id. 8vo, Leipzig, 1829.

**Haid., Handb.** Handbuch d. bestimmenden Mineralogie; by id. 8vo, Vienna, 1845.

**Haid., Ueb.** Uebersicht der Resultate mineralogischer Forschungen im Jahre 1843; by id. Erlangen, 1845.

**Hartmann, Handwörterb.** Handwörterbuch der Mineralogie und Geologie; by Hartmann. Leipzig, 1828. Also Handbuch d. Min., 2 vols. Weimar, 1843.

**Hausm., Versuch.** Versuch eines Entwurfs zu einer Einleitung in die Oryktognosie; by J. F. L. Hausmann. 8vo, Braunschweig, 1805; Cassel, '09.

**Hausm., Handb., 1813, 1847.** Handbuch der Mineralogie; by id. 3 vols. 12mo, Göttingen, 1813; 2d ed., 1st vol., introductory, '28; 2d, in two parts, '47.

**Hbg., Min. Not.** Mineralogische Notizen. 4to with plates, Frankfurt, 1–7, with Index in No. 7, 1854–'68; 8, '68; 9, '70; 10, '71; 11, 1873 (from the Abh. d. Senckenberg. nat. Gesellschaft, Frankfurt).

**Heddle, Min.** Chapter on Mineralogy in vol. 16 of the Encyclopædia Britannica (pp. 346 to 431); by M. Forster Heddle. 1883.

**Henckel, Pyrit.** Pyritologia, oder Kiess-Historie; by J. Fr. Henckel (of Saxony). 8vo, Leipzig, 1725.

**Hill, Foss.** Fossils arranged according to their obvious characters; by John Hill. 8vo, London, 1771. (De Lisle says it was not issued till 1772.)

**His., Min., Geogr. Swed.** Mineralogisk Geografi öfver Sverige; by W. Hisinger. 8vo, Stockholm, 1808. Also

**His. Min., Geogr. Wöhler.** Versuch einer mineralogischen Geographie von Schweden, übersetzt von F. Wöhler. 8vo, Leipzig, 1826.

**His., Handbok.** Handbok för Mineraloger under Resor i Sverige; by W. Hisinger. 8vo, Stockholm, 1843.

**Hintze, Min.** Handbuch der Mineralogie; by C. Hintze. Vol. 2, Lief. 1–5, pp. 1–800 (Silicates, pt.). Leipzig, 1889 to 1891.

**Höfer, Min. Kärnth.** Die Mineralien Kärnthens; by A. Höfer. 84 pp. 8vo, Klagenfurt, 1870.

**Hoff Mag.** Magazin für die gesammte Min., etc.; by K. E. A. v Hoff. 1 vol. 8vo, Leipzig, 1801.

**Hofmann, Min.** Handb. d. Mineralogie; by C. A. S. Hofmann. 4 vols. 8vo, Freiberg. Vol.

1, 1811; 2, part *a*, '12, *b*, '15; 3, parts *a*, *b*, '16; 4, part *a*, '17, *b*, '18. Work, after 2d vol. part *a*, issued by Breithaupt, Hofmann having died March, 1813. Vol. 4, part *b*, consists of notes and additions by Breithaupt, and includes also the Letztes Min. Syst. of Werner (1817).

**Hunt, Min. Physiology.** Mineral Physiology and Physiography; a second series of Chemical and Geological Essays; by Thomas Sterry Hunt. 710 pp. 8vo, Boston, 1886.

**Hunt, Syst. Min.** Systematic Mineralogy based on a Natural Classification; by T. S. Hunt. 391 pp. 8vo, New York, 1891.

**Huot, Min.** Manuel de Minéralogie; by J. J. N. Huot. 2 vols. 16mo, Paris, 1841.

**Jameson, Min., 1804, 1816, 1820.** A System of Mineralogy; by R. Jameson. 8vo, Edinburgh; 1st ed., 2 vols., 1804; 2d, 3 vols., '16; 3d, 3 vols., 1820.

Published also a Manual of Min., 8vo, in 1821, and Mineralogy according to the Natural System (from Encycl. Brit.), in 1837; also, in 1805, a Treatise on the External Characters of Minerals, 8vo, Edinburgh.

**Jasche, Kl. Schrift.** Kleine min. Schriften; by C. F. Jasche. 12mo, Sondershausen, 1817.

**John, Untersuch.** Chemische Untersuchungen mineralischer, etc., Substanzen; by J. Fr. John. 8vo, Berlin, Fortsetzung d. chem. Laboratoriums, Berlin, which makes vol. 1 of series; vol. 2, '10; 3, '13; 4, '16; 6, '21.

**Karsten, Mus. Lesk.** Museum Leskeanum, Regnum minerale; by D. L. G. Karsten. 2 vols. 8vo. Leipzig, 1789.

**Karst., Tab., 1791.** Tabellarische Uebersicht der mineralogisch-einfachen Fossilien; by id. Fol., Berlin, 1791.

**Karst., Tab., 1800, 1803.** Mineralogische Tabellen; by id. Fol., Berlin, 1800; 2d ed., fol., Berlin, 1808.

**Karst., Wern. Verbess. Min.** Ueber Herrn Werners Verbesserungen in der Mineralogie auf Veranlassung der freimüthigen Gedanken, etc., des Herrn Abbé Estner; by id. 80 pp. 12mo, Berlin, 1793.

**Kbl., Char.** Charakteristik d. Mineralien; by Fr. von Kobell. 8vo, Nürnberg, Abth. 1, 1830; 2, 1831.

**Kbl., Min.** Grundzüge d. Mineralogie; by id. 8vo, Nürnberg, 1838.

**Kbl., Taf., 1853.** Tafeln zur Bestimmung d. Mineralien; by id. 5th ed., München, 1853. 8th ed., 1864; 11th ed., 1878.

**Kbl. Min.-Namen.** Die Mineral-Namen; by id. 8vo. München, 1853.

**Kbl., Gesch. Min.** Geschichte d. Min.; by id. 8vo, München, 1864.

**Kenng., Ueb.** Uebersichte der Resultate mineralogischer Forschungen; by G. Ad. Kenngott. For the years 1844–'49, Wien, 1852; for years 1850–'51, Wien, 1853; for '54, Wien, 1854; for '53, Leipzig, 1855; for '54, ib., 1856; for '55, ib., 1856; for '56, '57, ib., 1858; for '58, ib., 1860; for '59, ib., 1860; for '60, ib., 1862; for '61. ib., 1862; for '62–'65, ib., 1868.

**Kenng., Min, 1853.** Das Mohs'sche Mineralsystem; by id. 8vo, Wien, 1853.

**Kenng. Min. Unt.** Mineralogische Untersuchungen; by G. A. Kenngott. Part 1, 77 pp. 8vo, Breslau, 1849; 2, pp. 77–156, 1850.

**Kirwan, Min.** Elements of Mineralogy; by R. Kirwan. 2 vols. 8vo, London, 2d edition, 1794–6. 1st ed. was issued in 1784, 8vo.

**Kk., Min. Russl.** Materialen zur Mineralogie Russlands; by N. v. Koksharov. 8vo, St. Petersburg. Vol. 1, 1853–54; 2, '54–'57; 3, '58; 4, '61–'66; 5, '66–'69; 6, '70–'74; 7, '75–'77; 8, '78–'83; 9, '84–'86; 10, '88–'91. Also Atlas, Tafeln i to lxxxvii.

Also by same author, Vorlesungen über Mineralogie. Vol. 1, 4to, St. Petersburg, 1865.

**Klapr., Beitr.** Beiträge zur chemischen Kenntniss d. Mineralkörpers; by M. H. Klaproth. 8vo, vol. 1. 1795; 2, '97; 3, 1802; 4, '07; 5, '10; 6, '15.

**Klein, Kryst.** Einleitung in die Krystallberechnung; by Carl Klein. 393 pp., 8vo, Stuttgart, 1875.

**Knop, Anorgan.** System der Anorgraphie; by A. Knop. 8vo, Leipzig, 1876.

**Kopp, Gesch. Ch.** Geschichte d. Chemie; by H. Kopp. 4 parts, 8vo, Braunschweig, 1843–47.

**Kronstedt.** See **Cronstedt.**

**Kunz, Gems, N. A.** Gems and Precious Stones of North America; by G. F. Kunz, 336 pp. 8vo. New York, 1890.

**Kupffer, Preisschrift.** Preisschrift über genaue Messung der Winkel der Krystallen; 135 pp. 4to, Berlin, 1825 (Gekrönt—K. preuss. Akad. Wiss., 3 Juli, 1823). **Also by id.**, Handbuch der rechnenden Krystallonomie. St. Petersburg, 1831.

**Lampadius, Samml.** Sammlung practisch-chemischer Abhandlungen; by W. A. Lampadius. 3 vols. 8vo, Dresden. Vol. 1, 1795; 2, 1797; 3, 1800.

**Landero, Min.** Sinopsis Mineralógica ó catálogo descriptivo de los Minerales; by **Carlos F. De** Landero. 528 pp., Mexico, 1888–91.

**Lapparent Min.** Cours de Minéralogie; by A. de Lapparent. 560 pp., Paris, 1884.

**Lenz, Min.** Versuch einer vollständigen Anleitung zur Kenntniss der Mineralien; by D. G. J. Lenz. 2 vols. 8vo, Leipzig, 1794. By the same, Tabellen, 1781; Handbuch, 1791; Grundriss, 1793; Mustertafeln, 1794; Tabellen, fol., 1806; System, 1800, 1809; Handbuch, 1822.

**Leonh., Syst.-Tab.** Systematisch-tabellarische Uebersicht und Char. d. Mineralkörper; by C. C. Leonhard, K. F. Merz, and J. H. Kopp. Fol., Frankfurt a. M., 1806.

**Leonh., Orykt.** Handbuch der Oryktogonosie; by K. C. Leonhard. 8vo, Heidelberg, 1821. Also 2d ed., 8vo, Heidelberg, 1826.

**Leonh., topogr. Min.** Handwörterbuch d. topographischen Mineralogie; by G. Leonhard. Heidelberg, 1843.

**Lévy's Heuland** or **Lévy Min.** Description d'une collection de Minéraux, formée par M. Henri Heuland, et appartenant à M. Ch. H. Turner, de Rooksnest, dans le comté de Surrey en Angleterre; by A. Lévy. 3 vols. 8vo, with an atlas of 83 pl., London, 1837.

**Lévy-Lcx., Min. Roches.** Les Minéraux des Roches; by A. Michel-Lévy and Alf. Lacroix. 334 pp., Paris, 1888.

**Libavius, Alchem.** Alchemia, A. Libaviæ. Frankfurt, 1597.

**Liebisch, Geom. Kryst.** Geometrische Krystallographie; by Th. Liebisch. 464 pp. 8vo, Leipzig, 1881.

**Liebisch, Phys. Kryst.** Physikalische Krystallographie; by id. 614 pp. 8vo, Leipzig, 1891.

**Liversidge, Min. N. S. W.** The Minerals of New South Wales; by Archibald Liversidge. First published in Trans. R. Soc., N. S. W., Dec. 1874. 2d ed., 137 pp., Sydney, 1882 (Min. Prod. N. S. W., pp. 65–199). 3d ed., 326 pp. 8vo, London, 1888.

**Linn., Syst. Nat.** Systema Naturæ of Linnæus 1st ed., 1735; 10th ed., T. 3, 1770.

**Lucas, Tabl.** Tableau méthodique des Espèces Minéraux; by J. A. H. Lucas. Part 1, 8vo, 1806; 2, 1813, Paris. The first part contains brief descriptions taken from Haüy's work, and also from his subsequent lectures and published announcements of his courses. The second includes in the main Haüy's Tabl., with many additional notes.

**Ludwig's Min.**, or **Ludwig's Wern.** Handbuch d. Mineralogie nach A. G. Werner; by C. F. Ludwig. 2 vols. 8vo, Leipzig, 1803, '04.

**Mallet, Min. India.** A Manual of the Geology of India. Part IV, Mineralogy (mainly non-economic); by F. R. Mallet. 179 pp. 8vo, Calcutta, 1887.

**Marx, Crystallkunde.** Geschichte der Crystallkunde; by Dr. C. M. Marx. 8vo, Carlsruhe and Baden, 1825.

**Matthesius, Sarepta** Berg Postilla, oder Sarepta; by J. Matthesius. Fol., Nürnberg, 1562.

**Meunier, Météorites.** Météorites; by Stanislas Meunier. 532 pp. 8vo, Paris, 1884 (Encycl. Chimique, by M. Frémy).

**Meunier, Synth. Min.** Les Méthodes de Synthèse en Minéralogie; by Stanislaus Meunier. 359 pp. 8vo, Paris, 1891.

**Min. India.** See **Mallet, Min. India**.

**Min. Res. U. S.** Mineral Resources of the United States. 1, 2, edited by Albert Williams, for 1882; 2, 1883–84; 3–6 by David T. Day; 3, 1885; 4, 1886; 5, 1887; 6, 1888; 7, 1889–90 (in preparation).

**Min.-Samml. Strassburg.** See **Groth, Min.-Samml.**

**Mld., Crist** Traité de Cristallographie géométrique et physique; by Ernest Mallard. 8vo, vol. 1, 372 pp., Paris, 1879; vol. 2, Cristallographie physique, 599 pp., 1884.

**Mld., Opt. Anom.** Explication des phénomènes optiques anomaux, que présentent un grand nombre de substances cristallisées. Paris, 1877. Ann. Mines, 7th ser., vol. 10, pp. 60–196, 1876 (Abstr. Zs. Kr., 1, 309, 1877).

**Mohs, Null Kab.** Des Herrn J. F. Null Mineralien-Kabinet, nach einem, durchaus auf aussere Kennzeichen gegründeten Systeme geordnet; by F. Mohs. 3 Abthl., 8vo, Vienna, 1804.

**Mohs, Char.** Characteristic of the Natural History System of Mineralogy; by id. 8vo, Edinburgh, 1820.

**Mohs, Min., 1822.** Grundriss der Mineralogie; by id. 8vo, vols. 1, 2, 1822, '24, Dresden. (Translated into English by W. Haidinger. See **Haid.**)

**Mohs, Min., 1839.** Anfangsgründe der Naturgeschichte des Mineralreichs; by F. Mohs. Zweiter Theil bearbeitet von F. X. M. Zippe; 8vo, Vienna, 1839 (Erster Theil, introtory, published in 1836). A first edition of this work in 1832.

**Mont. & Cov., Min.** Prodromo della Mineralogia Vesuviana; vol. 1, Orittognosia. 8vo, Naples, 1825.

**Napione, Min.** Elementi di Mineralogia; by Napione. 8vo, Turin, 1770.

**Naumann, Kryst.** Lehrbuch der Krystallographie; by C. F. Naumann. 2 vols. 8vo, with numerous figs., Leipzig, 1829. Naumann later published the smaller works, Anfangsgründe der Kryst., 8vo, 1854; Elemente der theoretischen Kryst., 8vo, 1856.

**Naumann, Min.** Elemente der Mineralogie. 8vo, Leipzig, 1st ed., 1846; 2d, '50; 3d, '52; 4th, '55; 5th, '59; 6th, '64; 7th, '68; 8th, '70; 9th, '73. Later revised by Zirkel. See **N.-Z. Min.**

Naumann published also, Lehrbuch der Min., 8vo, Berlin, 1828.

**Necker, Min.** Le règne minéral ramené aux méthodes de l'histoire naturelle; by L. A. Necker. 2 vols. 8vo, Paris, 1835.

**Nicol, Min.** Manual of Mineralogy; by J. Nicol. 8vo, Edinburgh, 1849.

**Nöggerath, Min. Stud. Geb. Niederrhein.** Mineralogische Studien über die Gebirge am Niederrhein; by J. J. Nöggerath. 8vo, Frankfurt a. M., 1808.

**A. E. Nd., Finl. Min.** Beskrifning öfver de i Finland funna Mineralier; by A. E. Nordenskiöld. 8vo, Helsingfors, 1855. Also 2d ed., ib., 1863.

**N. Nd., Finl. Min.** Bidrag till närmare Kännedom af Finlands Mineralier och Geognosie; by Nils Nordenskiöld. 8vo, Stockholm, 1820.

**N. Nd., Verz.** Verzeichn. d. in Finland gef. Min.; by id. Helsingfors, 1852.

**N.-Z., Min.** Elemente der Mineralogie by C. F. Naumann, 10th ed. revised by F. Zirkel, 714 pp. 8vo, 1877. 11th ed. by Zirkel, 735 pp., Leipzig, 1881. 12th ed., 782 pp., 1885.

**Phillips, Min., 1823, 1837.** Elementary Introduction to Mineralogy. 8vo, 3d ed., London, 1823. 4th ed. by R. Allan, 8vo, 1837. The 1st ed. appeared in 1816; and this was republished in New York, in 1818. For Alger's Phillips, see **Alger**; for Brooke & Miller's Phillips (1852), see **B. & M. Min.**

**Pisani, Min.** Traité élémentaire de Minéralogie by F. Pisani. 415 pp. 8vo, Paris, 1875. 2d ed., 421 pp., 1883.

**Plattner, Probirk.** Die Probirkunst mit dem Löthrohr; by C. F. Plattner. Edited by T. Richter, 8vo, 1865. (A translation by H. B. Cornwall, assisted by J. H. Caswell, New York, 1872.) 5te Auflage, T. Richter, 1877–78.

**Plin.** Historia Naturalis C. Plinii Secundi. First published A.D. 77. Latin ed. consulted, Sillig's, in 8 vols., 1851–58; and English, that of Bostock & Riley, 5 vols. 12mo, London, 1855. Pliny's Natural History is divided into xxxvii Books; and these into short chapters. The numbering of the chapters differs somewhat in different editions; that stated in the references is from the English edition. The last five books are those that particularly treat of metals, ores, stones, and gems.

**Quenstedt Kryst.** Grundriss der bestimmenden und rechnenden Krystallographie nebst einer historischen Einleitung; by Fr. Aug. Quenstedt. 443 pp., Tübingen. 1873.

**Quenstedt, Min.** Handbuch der Mineralogie; by F. A. Quenstedt. 8vo, Tübingen, 1853. Also 2d ed., ib., 1863; 3d ed., ib., 1877.

**Raimondi, Min. Pérou.** Minéraux du Pérou: Catalogue raisonné d'une collection des principaux types minéraux de la République; by A. Raimondi. Translated from the Spanish by J.-B. H. Martinet. 336 pp. 8vo, Paris, 1878.

**Rashleigh, Brit. Min.** Specimens of British Minerals selected from the cabinet of Philip Rashleigh (descriptions and colored plates). 4to, London. Part 1, 1797; 2, 1802.

**Rep. G. Cal.** Report on the Geology of California; by J. D. Whitney. Large 8vo, San Francisco, 1865.

**Rep. G. Can.** Annual Reports on the Progress of the Geological Survey of Canada; by Sir Wm. E. Logan. Containing reports on mineralogy by T. S. Hunt. 8vo, 1845–'59. In 1863 a General Report for the years 1843–'63. Also Annual Reports for later years with mineralogy by B. J. Harrington and G. Chr. Hoffmann.

**Rep. G. Mass.** Report on the Geology of Massachusetts; by E. Hitchcock. 1st Rep., 1833, 8vo; 2d ed., 1835. 2d Rep., 1841, 4to.

**Rep. G. N. Y.** Reports on the Geological Survey of New York. Annual Reports in 8vo, 1837–'41; final in 4to.

**Rep. Min. N. Y.** Report on the Mineralogy of the State of New York; by L. C. Beck. 4to, 1842.

☞ [The many Geological Reports published both for the general government as also for the different states during recent years cannot be mentioned in detail. See, however, **U. S. G. Surv.**]

**Reuss, Min.** Lehrbuch d. Mineralogie; by F. A. Reuss. 8vo, 1801–05, Leipzig. Divided into parts, and the parts into vols. Pt. 1 and pt. 2, vol. 1, 1801; vol. 2, '02; vol. 3, 4, '03; 3d pt., vol. 1, 2, '05; 4th pt., including Index, '06.

**Rg., Handw.** Handwörterbuch des chemischen Theils der Mineralogie; by C. F. Rammelsberg. 8vo, Berlin, 1841. Supplement 1, '43; 2, '45; 3, '47; 4, '49; 5, '53.

**Rg., Kr. Ch.** Handbuch der krystallographisch-physikalischen Chemie. Abtheilung I: Elemente und anorganische Verbindungen. 615 pp. 8vo, Leipzig, 1881. Abth. II: Organische Verbindungen, 1882.

**Rg., Min.** J. J. Berzelius's neues chemisches Mineralsystem; by id. 8vo, Nürnberg, 1847.

**Rg., Min. Ch. 1860, 1875.** Handb. d. Mineralchemie; by id. 8vo, Leipzig, 1860. Do., 2d ed., part I, 136 pp.; part II, 744 pp., 1875. Ergänzungsheft (**Erg.**), 276 pp., 1886.

**Rio, Min.** Nuevo Sistema Minerale; by A. M. del Rio. Mexico, 1827.

**Rio, Orykt.** Elementos de Oryktognosia, ó del Conocimiento de los Fósiles, dispuestos segun los principios de A. G. Werner; by id. 4to, Mexico, 1795.

**Rio, Tabl. Min.** Tablas mineralogicas por D. L. G. Karsten; by A. M. del Rio. 4to, Mexico, 1804.

**Robinson, Cat.** Catalogue of American Minerals, with their Localities; by S. Robinson. 8vo, Boston, 1825.

**Rose, Reis. Ural.** Reise nach dem Ural, dem Altai, und dem Kaspischen Meere; by Gustav Rose 8vo, Berlin; vol. 1, 1837; 2, '42.

**Rose, Kryst.-Ch. Min.** Das Krystallo-chemischen Mineral-System; by G. Rose. 8vo, Leipzig, 1852.

**Rose Kryst.** Elemente der Krystallographie. See **Rose-Sbk., Kryst.**, also **Sbk. Ang. Kryst.**, and **Websky, Kryst.**

**Rose-Sbk., Kryst.** Gustav Rose's Elemente der Krystallographie, 3d ed., vol. 1, 181 pp., 1873.

**Rosenb., Mass. Gest.** Mikroskopische Physiographie der massigen Gesteine; by H. Rosenbusch. 596 pp. 8vo, Stuttgart, 1877. 2d ed., 877 pp., 1886–87.

**Rosenb., Mikr. Phys.** Mikroskopische Physiographie der petrographisch-wichtigen Mineralien; by H. Rosenbusch. 398 pp. 8vo, Stuttgart, 1873; 2d ed., 664 pp., 1885. Also accompanied by Hülfstabellen zur mikroskopischen Mineralbestimmung, Stuttgart, 1888.

**Rosenbusch-Iddings, Micr. Phys.** English translation and abridgment of the above work. 333 pp., New York, 1888.

**Roth, Ch. G.** Allgemeine und chemische Geologie; by Justus Roth. Vol. 1, Bildung u. Umbildung der Mineralien, etc., 633 pp., Berlin, 1879. 2, Petrographie, 695 pp., 1887.

**Sage, Min.** Élémens de Minéralogie docimastique; by B. G. Sage. 2d ed., 2 vols., 1777. 1st ed. appeared in 1772.

**Sandb., Unt. Erzgänge.** Untersuchungen über Erzgänge von Fridolin Sandberger. 430 pp. 8vo, Wiesbaden, 1882–85.

**Saussure, Voy. Alpes.** Voyages dans les Alpes, par H. B. Saussure. 4 vols. 4to. Vols. 1, 2, 1779, '80; 3, 4, '96.

**Sbk., Ang. Kryst.** Angewandte Krystallographie (Ausbildung der Krystalle, Zwillingsbildung, Krystallotektonik) nebst einem Anhang über Zonenlehre; by Alexander Sadebeck (Rose's Elemente der Krystallographie, II. Band). 284 pp. 8vo, Berlin, 1876.

**Sbk., Kryst.** See **Rose-Sbk.**

**Scacchi, Mem. Min. e Geol.** Memorie mineralogiche e geologiche; by A. Scacchi. 8vo, Napoli, 1841.

**Scacchi, Crist.** Quadri Cristallografici, e Distribuzione sistematica dei minerale; by id. 8vo, Napoli, 1842.

**Scacchi, Mem. G. Campania.** Memorie geologiche sulla Campania; by id. 4to, Napoli, 1849. By the same, Memoria sulla Incendio Vesuviano, 1855. Napoli, 1855. Polisimmetria dei Cristalli. 4to, 1864.

**Scacchi, Contr. Min.** Contribuzioni mineralogiche per servire alla Storia dell' Incendio Vesuviano, del mese di Aprile. 1872. Part I, Naples, 1872; Part II, Naples. 1874.

**Scacchi, Min. Vesuv.** Catalogo dei Minerali Vesuviani. Naples, 1887. Also Catalogo dei Minerali e delle Rocce Vesuviane per servire alla Storia del Vesuvio ed al commercio dei suoi prodotti, 1889 (Att. Accad. Napoli, 4th ser., vol. 1).

**Schrauf, Atlas.** Atlas der Krystall-Formen des Mineralreiches. 4to, vol. 1, A–C., Vienna, 1865–1877. 1 Lief., Tf. i–x, 1865; 2, Tf. xi–xx, 1871; 3, Tf. xxi–xxx, 1872; 4, Tf. xxxi–xl, 1873; 5, xli–l, 1875.

**Schrauf, Edelsteinkunde.** Handbuch der Edelsteinkunde; by Albrecht Schrauf. 252 pp. 8vo, Vienna, 1869.

**Schrauf, Phys. Min.** Lehrbuch der physikalischen Mineralogie. 8vo, vol. 1, 253 pp., 1866; vol. 2, 426 pp., Vienna, 1868.

**Schumacher, Verz.** Versuch eines Verzeichnisses der in den Dänisch-Nordischen Staaten sich findenden einfachen Mineralien. 4to, Copenhagen, 1801.

**Schütz, Nordamer. Foss.** Beschreibung einiger nordamerikanischen Fossilien; by A. G. Schütz, of Freyberg. 16mo, Leipzig, 1791. Contains the first notice of *celestine*, a mineral named by Werner from Schütz's American specimens.

**Sella, Min. Sarda.** Studii sulla Mineralogia Sarda; by Quintino Sella. 4to, Turin, 1856.

**Selle, Min.** Cours de Minéralogie et de Géologie, by Albert de Selle. Vol. 1, Minéralogie, 589 pp. 8vo, Paris, 1878.

**Senft, Min.** Synopsis der Mineralogie und Geognosie; by F. Senft. 1te Abtheilung, Mineralogie, 931 pp. 8vo, Hannover, 1875.

**Shep., Min., 1832–1835, 1844, 1852, 1857.** Treatise on Mineralogy; by C. U. Shepard. 1st part, 1 vol. 12mo. New Haven, 1832; 2d part, 2 vols., New Haven, 1835. Also, 2d ed. (with only the 1st part revised), New Haven, 1844. Also, 3d ed., 8vo, New Haven, No. 1, 1852; No. 2, '57.

**Shep., Min. Conn.** Report on the Geological Survey of Connecticut; by id. 8vo, N. Haven, 1837.

**Sohncke, Kryst.** Entwickelung einer Theorie der Krystallstruktur; by L. Sohncke. 247 pp. 8vo, Leipzig, 1879.

**Steffens, Handb.** Handb. d. Oryktognosie; by H. Steffens. 3 vols. 18mo, Halle; vol. 1, 1811; 2 '15; 3, '19.

**Stromeyer, Unt.** Untersuchungen über die Mischung der Mineralkörper, etc.; by Fr. Stromeyer. 8vo, Göttingen, 1821.

**Tabl. Min.** See **Adam, Tabl. Min.**

**Theophr.** Theophrastus Περί λίθων (on Stones); written about 315 B.C. Only a portion of the whole work is extant, but sufficient to show that the author was precise in his knowledge of minerals and careful in the statement of facts. T. born about 371 B.C., and d. 286 B.C.

**Thomson, Min., 1802, 1836.** Outlines of Mineralogy, Geology, and Mineral Analysis; by T. Thomson. 2 vols. 8vo, London, 1836. A treatise on Mineralogy published also with preceding editions of his Chemistry, the earliest in 1802.

**Traube, Min. Schlesiens.** Die Minerale Schlesiens; by H. Traube. 285 pp. 8vo, Breslau, 1888.

**Tsch., Min.** Lehrbuch der Mineralogie, von Dr. Gustav Tschermak. 589 pp. 8vo, Vienna, 1885. 3d ed., 1888.

**Ullmann, Syst.-tab. Ueb.** Systematisch-tabellarische Uebersicht der min.-einfachen Fossilien; by J. C. Ullmann. Small 4to, Cassel and Marburg, 1814.

**Ulrich, Contr. Min. Vict.** Contributions to the Mineralogy of Victoria; by G. H. F. Ulrich. 32 pp. 8vo, Melbourne, 1870.

**U. S. G. Surv.** United States Geological Survey.

—— **Bull.** Bulletins 1 to 81. 8vo. A catalogue of those previously issued is given with each number.

—— **Ann. Rep.** Annual Reports. 4to. Vol. 1, for 1880–81; 10 for 1888–89.

—— **Mon.** Monographs. 4 to Vols. 1 to 16.

**Vogl's Joach.** Gängverhältnisse und Mineralreichthum Joachimsthals; by J. Fl. Vogl. 8vo, Teplitz, 1857.

**Volger, Studien, etc.** Studien zur Entwicklungsgeschichte der Mineralien; by G. H. O. Volger. 8vo, Zürich, 1854. Other works: Entwickl. der Min. d. Talk-Glimmer Familie, 1855; Arragonit und Kalcit, 1855; Monographie des Borazites, Hannover, 1855; Epidot und Granat, Beobachtungen über das gegenseitige Verhältniss dieser Krystalle, Zürich, 1855; Krystallographie, Stuttgart, 1854.

**Wall.,** or **Wall., Min.** Mineralogia, eller Mineralriket; by J. G. Wallerius. 12mo, Stockholm, 1747.

**Wall., Fr. Trl.** French edition of Wallerius's Min. of 1747. 2 vols. 8vo, Paris, 1753. Published anonymously.

**Wall., Min., 1772, '75.** Systema Mineralogicum. 8vo, Holmiæ, vol. 1, 1772; 2, '75.

**Wall., Min., 1778.** Syst. Min. 2 vols. 8vo, Vienna, 1778.

**Waltersh., Vulk. Gest.** Ueber die vulkanischen Gesteine in Sicilien und Island [Iceland], und ihre submarine Umbildung; by W. Sartorius v. Waltershausen. 8vo, Göttingen, 1853.

**Watts, Dict. Ch.** Dictionary of Chemistry; by H. Watts. 5 vols.; 1 in 1863; with supplements. Two volumes (A—In) of a revised edition have been published, 1888, '89, edited by H. F. Morley and M. M. Pattison Muir.

Also two volumes of a companion-work, Dictionary of Applied Chemistry, edited by T. E. Thorpe, 1890, '91.

**Websky, Kryst.** Anwendung der Linearprojection zum Berechnen der Krystalle; by Martin Websky (Rose's Elemente der Krystallographie, III Band). 377 pp. 8vo, Berlin, 1887.

**Websky, Min. Sp. G.** Die Mineral Species nach den für das specifische Gewicht derselben angenommenen und gefundenen Werthen; by Martin Websky. 170 pp. 4to, Breslau, 1868.

**Weisbach, Synops. Min.** Synopsis Mineralogica, systematische Uebersicht des Mineralreiches; by Albin Weisbach. 78 pp. 8vo, Freiberg, 1875. 2d ed., 1884.

**Wern., Auss. Kennz. Foss.** Von d. äusserlichen Kennzeichen d. Fossilien; by A. G. Werner. 8vo, Leipzig, 1774.

**Wern., Letzt. Min. Syst.** Letztes Mineral-System. 8vo, Freiberg & Wien, 1817. A Catalogue with notes. Werner or his scholars issued, from time to time, a tabular synopsis of his Mineral System revised to the time of publication, on folio sheets, or published them in other works. The earliest after that of Werner's Cronstedt was issued by Hofmann in Bergm. J., 1789, vol. 1, p. 369. Emmerling's Min., vol. 1, 1799, contains the synopsis of 1798, and Ludwig's Min. contains that of 1800 and 1803. Leonhard's Tasch., vol. 3, 261, that of 1809.

**Wern., Min.-Kab. Pabst.** Verzeichniss des Mineralien-Kabinets des Herrn K. E. Pabst von Ohain; by A. G. Werner. 2 vols., Freiberg, 1791, '93.

**Wern., Ueb. Cronst.** Cronstedt's Versuch einer Min. übersetzt und vermehrt von A. G. Werner. Vol. 1, part 1, Leipzig, 1780.

**Westrumb, Kl. Phys.-Ch. Abh.** Kleine physikalisch-chemische Abhandlungen; by J. F. Westrumb. 8vo, Leipzig, vol. 1, 1785; 2, '87; 3, '88; 4, '89; Hannover, 5, 6, '93; 7, '95; 8, '97.

**Whitney, Lake Sup.** Report on the Geology of the Lake Superior Land District; by J. W. Foster and J. D. Whitney. 8vo, Part 1, 1850; 2, '51.

**Whitney, Met. Wealth.** The Metallic Wealth of the United States, described and compared with that of other countries; by J. D. Whitney. 8vo, Philadelphia, 1854.

**Whitney, Miss. Lead Region.** Report of a Geological Survey of the Upper Mississippi Lead Region; by id. (Made by authority of the State of Wisconsin.) 8vo, 1862.

**Whitney, Rep. G. Cal.** See **Rep. G. Cal.**

**Whitney, Berz. Blowpipe.** Berzelius on the Blowpipe; translated by J. D. Whitney. 8vo, Boston, 1845.

**Withering, Trl. Bergm. Sciagr.** Outlines of Mineralogy, trl. from the original of Bergmann; by Wm. Withering. 8vo, 1783. (Reprinted in vol. 2 of Mem. and Tracts of the late Dr. Withering, London, 1822.)

**Wiik, Min.-Kar.** Mineral-Karakteristik: En Handledning vid Bestämmandet af Mineralier och Bergarter; by F. J. Wiik. 218 pp. 12mo, Helsingfors, 1881.

**Williams, Cryst.** Elements of Crystallography for Students of Chemistry, Physics, and Mineralogy; by G. H. Williams. 250 pp. 12mo, New York, 1890.

**Woodward, Foss.** Fossils of all kinds digested into a Method suitable to their mutual Relation and Affinity. 8vo, London, 1728.

**Zepharovich, Min. Lex.** Mineralogisches Lexicon für das Kaiserthum Oesterreich; by V. R. v. Zepharovich. 8vo, Vienna, 1859. Vol. 2, ibid., 1873.

**Zirkel, Mikr. Besch.** Die mikroscopische Beschaffenheit der Mineralien und Gesteine; by Ferdinand Zirkel. 502 pp. 8vo, Leipzig, 1873.
See also **N.-Z., Min.**

The works in the above catalogue which are most important for the study of the history of mineral species are the following, the order cited being that of time:

Theophrastus; Dioscorides; Pliny's Natural History; Agricola's works; Linnæus's Systema Naturæ, 1st ed., 1735; Wallerius's Mineralogy in the original Swedish, 1747 (the first systematic, descriptive work, following in its system of classification mainly the 1st edition of Linnæus, which the author alludes to in his preface, among other Swedish works by Forsius, Hiærne, Bromell, and Swedenborg); Cronstedt's Mineralogy, 1757 (a new chemical system); Linnæus's Systema Naturæ, 10th ed., 1768; Romé de Lisle's Crystallography, 1772, 1783 (the first systematic effort to apply the principles of crystallography to the science); Wallerius's Min. of 1772, 1778 (the system and facts are little changed from the earlier edition); Werner on the External Characters of Minerals, 1774, and his Cronstedt, 1780; Bergmann's Opuscula, 1780, and Sciagraphia, 1782; Hofmann's exposition of Werner's system in the Bergm. J., 1789; Emmerling's Mineralogy, 1793–'97, and 1799–1802; Lenz's Mineralogy, 1794; Klaproth's Beiträge, 1795–1810; Karsten's Tabellen, 1800; Haüy's Treatise on Mineralogy, 1801; Reuss's Mineralogy, 1801–1806; Ludwig's Werner, 1803, 1804; Mohs's Null Kab., 1804; Karsten's Tabellen, 1808; Lucas's Tableau, part 1, 1806 (giving views of Haüy of 1801 to 1806); Brongniart's Mineralogy, 1807; Haüy's Tableau comparatif, 1809; Hausmann's Handbuch, 1813; Hoffmann's Mineralogie, 1811–1817; Ullmann's Uebersicht, 1814; Jameson's Mineralogy, 1816, 1820; Werner's Last Mineral System (Letztes, etc.), 1817; Cleaveland's Mineralogy, 1816, 1822; Berzelius's Nouv. Système, 1819; Leonhard's Handbuch, 1821, 1826; Mohs's Mineralogy, 1822; Haidinger's translation of Mohs, 1825; Breithaupt's Charakteristik, 1820, 1823, 1832; Beudant's Treatise, 1824, 1832; Phillips's Min., 1823, 1837; Glocker's Min., 1831, 1839; Shepard's Min., 1832–'35, and later editions; von Kobell's Grundzüge, 1838; Mohs's Min., 1839; Breithaupt's Min., 1836–1847; Haidinger's Handbuch, 1845; Hausmann's Handbuch, 1847; Dufrénoy's Min., 1844–1847 (also 1856–1859); Glocker's Synopsis, 1847; Brooke & Miller, 1852; Rammelsberg's Handwörterbuch and Supplements, 1841–1853, also his Mineralchemie, 1860, 1875; Hessenberg's Notizen, 1854 to 1873; Koksharov's Mineralogie Russlands, 1854 to 1891; Kenngott's Uebersicht, 1844–1865; Des Cloizeaux's Mineralogy, 1862, 1874; von Kobell's Geschichte, 1864; Naumann's Min. (and Naumann-Zirkel), 1846 to 1885; Tschermak's Min., 1881; Goldschmidt's Index, 1886–'91; Hintze's Min. (1889–'91), five parts only completed, but with greater detail of treatment than has been before attempted. To the above list are to be added the earlier editions of this work by James D. Dana, 1837, 1844, 1850, 1854, 1868.

## 2. ABBREVIATED NAMES OF THE UNITED STATES (U. S.).

| | |
|---|---|
| **Ala.** | Alabama. |
| **Ark.** | Arkansas. |
| **Cal.** | California. |
| **Col., Colo.** | Colorado. |
| **Ct., Conn.** | Connecticut. |
| **Dak.** | Dakota. |
| **Del.** | Delaware. |
| **Ga.** | Georgia. |
| **Ill.** | Illinois. |
| **Ind.** | Indiana. |
| **Kan.** | Kansas. |
| **Ky.** | Kentucky. |
| **Mass.** | Massachusetts. |
| **Md.** | Maryland. |
| **Me.** | Maine. |
| **Mich.** | Michigan. |
| **Minn.** | Minnesota. |
| **Miss.** | Mississippi. |
| **Mo.** | Missouri. |
| **Mont.** | Montana. |
| **N. Car.** | North Carolina. |
| **N. H., N. Hamp.** | New Hampshire. |
| **N. J.** | New Jersey. |
| **N. Y.** | New York. |
| **O.** | Ohio. |
| **Pa., Penn.** | Pennsylvania. |
| **R. I.** | Rhode Island. |
| **S. Car.** | South Carolina. |
| **Tenn.** | Tennessee. |
| **Va.** | Virginia. |
| **Vt.** | Vermont. |
| **Wisc.** | Wisconsin. |

## 3. ABBREVIATIONS OF PROPER NAMES USED IN REFERENCES TO AUTHORS AND IN TITLES.

| | |
|---|---|
| **Ach.** | A. D'Achiardi, Pisa. |
| **Arz.** | A. Arzruni, Aachen. |
| **Baumh.** | H. Baumhauer, Lüdinghausen. |
| **Bdg.** | C. Bodewig, Cologne. |
| **Bgr.** | W. C. Brögger, Stockholm. |
| **Bkg.** | H. Bücking, Strassburg. |
| **Breith.** | J. F. A. Breithaupt (1791-1873). |
| **Brk.** | H. J. Brooke (1771-1857). |
| **Brz.** | A. Brezina, Vienna. |
| **Btd.** | E. Bertrand, Paris. |
| **E. S. D.** | E. S. Dana, New Haven. |
| **J. D. D.** | J. D. Dana, New Haven. |
| **Dbr.** | H. Dauber (1823-1861). |
| **Dmr.** | A. Damour, Paris. |
| **Dx.** | A. Des Cloizeaux, Paris. |
| **Erem.** | P. von Eremeyev, St. Petersburg (*Germ.* Jérémejew). |
| **Fzl.** | A. Frenzel, Freiberg. |
| **Gdt.** | V. Goldschmidt, Heidelberg. |
| **Grl.** | J. Grailich (1829-1859). |
| **H.** | R. J. Haüy (1743-1822). |
| **Haid.** | W. von Haidinger (1795-1871). |
| **Hausm.** | J. F. L. Hausmann (1782-1859). |
| **Hbg.** | Fr. Hessenberg (1810-1874). |
| **Hkl.** | W. Hankel, Leipzig. |
| **Hkr.** | R. Helmhacker, Leoben. |
| **Kbl.** | Fr. von Kobell (1803-1882). |
| **Kenng.** | A. Kenngott, Zürich. |
| **Kk.** | N. von Koksharov, St. Petersburg (*Germ.* Kokscharow). |
| **Kln.** | C. Klein, Berlin. |
| **Knr.** | J. A. Krenner, Buda-Pesth. |
| **Lasp.** | H. Laspeyres, Kiel. |
| **Lcx.** | A. Lacroix, Paris. |
| **Lsx.** | A. von Lasaulx (1839-1886). |
| **Mg.** | O. Mügge, Hamburg. |
| **Mgc.** | Ch. Marignac, Geneva. |

### 4. MISCELLANEOUS ABBREVIATIONS.

References are given below to the places in the preceding pages where the meaning of certain general terms, symbols, etc., is more fully explained.

| | |
|---|---|
| **Alt.** | Altered forms, p. xl. |
| **Anal.** | Analyses. |
| **Artif.** | Artificial forms, p. xl. |
| **Ax. pl.** | Optic axial plane, p. xxxv. |
| **B. B.** | Before the blowpipe, p. xl. |
| **Bx, $\mathbf{Bx_a}$** | Bisectrix, i.e. acute bisectrix or first mean line, p. xxxv. |
| **$\mathbf{Bx_o}$** | Obtuse bisectrix, or second mean line, p. xxxv. |
| **Comp.** | Composition, p. xxxvii *et seq.* |
| **G.** | Specific Gravity, p. xxxiv. |
| **H.** | Hardness, p. xxxiv. |
| **Obs.** | Observations, p. xiii. |
| **O. F.** | Oxidizing flame, p. xl. |
| **O. ratio** | Oxygen ratio, p. xxxix. |
| **priv. contr.** | Private contributions (i.e. of unpublished observations). |
| **pt.** | Part, in part. |
| **Pyr.** | Pyrognostics or blowpipe characters, p. xl. |
| **Ref.** | References (p. xiii); also used of abstracts of original articles found in certain journals, e.g. Jb. Min., Zs. Kr., etc. |
| **R. F.** | Reducing flame, p. xl. |
| **Tw. axis** | Twinning axis, p. xviii. |
| **Tw. pl.** | Twinning plane, p. xviii. |
| **Var.** | Varieties. |
| $a$, $b$, $\overset{\mid}{c}$, $\breve{a}$, $\bar{b}$, etc. | Crystallographic axes, p. xiv *et seq.* |
| $\mathfrak{a}$, $\mathfrak{b}$, $\mathfrak{c}$, | Axes of elasticity, p. xxxv. |
| $\alpha$, $\beta$, $\gamma$, | Axial angles, p. xxxii; also indices of refraction, p. xxxv. |
| 2E, 2V, 2H, 2K, 2G, | Optic axial angle in air, etc., p. xxxv. |

The following signs are frequently employed:

| | |
|---|---|
| +, −, | Plus and minus, as defining the optical character of crystals, p. xxxv. |
| ‖, | Parallel to, as *ax. pl.* ‖ *a*. |
| ⊥, | Perpendicular or normal to, as Bx ⊥ *c*. |
| ∧, | Angle between two forms, as $100 \wedge 110 = 45°$. |
| $\frac{2}{2}$, $\frac{3}{3}$, | Mean of two (or three, etc.) analyses; also, in some cases of separate determinations. |

All temperatures are given on the *Centigrade scale.*

# DESCRIPTIVE MINERALOGY.

---

## GENERAL CLASSIFICATION.

I. NATIVE ELEMENTS.

II. SULPHIDES, SELENIDES, TELLURIDES, ARSENIDES, ANTIMONIDES.

III. Sulpho-salts.—SULPHARSENITES, SULPHANTIMONITES, SULPHOBISMUTHITES.

IV. Haloids.—CHLORIDES, BROMIDES, IODIDES; FLUORIDES.

V. OXIDES.

VI. Oxygen-Salts.

- 1. CARBONATES.
- 2. SILICATES, TITANATES.
- 3. NIOBATES, TANTALATES.
- 4. PHOSPHATES, ARSENATES, VANADATES; ANTIMONATES. NITRATES.
- 5. BORATES. URANATES.
- 6. SULPHATES, CHROMATES, TELLURATES.
- 7. TUNGSTATES, MOLYBDATES.

VII. Salts of Organic Acids: Oxalates, Mellates, etc.

VIII. HYDROCARBON COMPOUNDS.

# I. NATIVE ELEMENTS.

**I. Non-Metals.** **II. Semi-Metals.** **III. Metals.**

## I. Non-Metals.

### 1. Carbon Group.

| | | | | |
|---|---|---|---|---|
| 1. | **Diamond** | C | Isometric | |
| 2. | **Graphite** | C | Rhombohedral | $\grave{c} = 1{\cdot}3859$ |

### 2. Sulphur Group.

| | | | | |
|---|---|---|---|---|
| 3. | **Sulphur** | S | Orthorhombic | $\breve{a} : \bar{b} : \grave{c} = 0{\cdot}8131 : 1 : 1{\cdot}9034$ |
| 4. | **Selensulphur** | (Se,S) | | |
| *5a.* | **Selenium** (artif.) | Se | Monoclinic, like the monoclinic forms of sulphur. | |

## II. Semi-Metals.

### 3. Tellurium-Arsenic Group. Rhombohedral.

| | | | *rr′* | *c* |
|---|---|---|---|---|
| 5*b.* | **Selenium** (artif.) | Se | 93° | — |
| 6. | **Selen-tellurium** | (Te,Se) | — | — |
| 7. | **Tellurium** | Te | 93° 3′ | 1·3298 |
| 8. | **Arsenic** | As | 94° 54′ | 1·4013 |
| 9. | **Allemontite** | $SbAs_3$ | | |
| 10. | **Antimony** | Sb | 92° 53′ | 1·3236 |
| 11. | **Bismuth** | Bi | 92° 20′ | 1·3036 |
| 12. | **Zinc** (only artif.?) | Zn | 93° 46′ | 1·3564 |

Zinc belongs with this rhombohedral group, and connects the semi-metals to the metals; it is also stated to be isometric like mercury.

## III. Metals.

### 4. Gold Group. Isometric.

| | | |
|---|---|---|
| 13. | **Gold** | Au |
| | Electrum | (Au,Ag) |
| 14. | **Silver** | Ag |
| 15. | **Copper** | Cu |
| 16. | **Mercury** | Hg |
| 17. | **Amalgam** | AgHg, $Ag_2Hg_3$, etc. |
| | 1. Arquerite | $Ag_{12}Hg$ |
| | 2. Kongsbergite | $Ag_{36}Hg$ |
| 18. | **Lead** | Pb |

---

| | | | | |
|---|---|---|---|---|
| 19. | **Tin** (cryst. only artif.) | Sn | Tetragonal | $\grave{c} = 0{\cdot}3857$ |
| | | | Orthorhombic | $\breve{a} : \bar{b} : \grave{c} = 0{\cdot}3874 : 1 : 0{\cdot}3557$ |

Tin is closely related to lead.

### 5. Platinum-Iron Group. Isometric, also in part Rhombohedral.

| | **Isometric.** | | | **Rhombohedral.** | | |
|---|---|---|---|---|---|---|
| 20. | **Platinum** | Pt with Fe<br>also with Ir, Rh, Os | | | | |
| 21. | **Iridium** | (Ir, Pt) | 22. | **Iridosmine** | (Ir,Os) | *rr′* = 95° 8′ |
| | Platiniridium | (Pt, Ir) | | 1. Siserskite | | $\grave{c} = 1{\cdot}4105$ |
| | | | | 2. Nevyanskite | | |

| Isometric. | | Rhombohedral. | |
|---|---|---|---|
| 23. **Palladium** | Pd | 24. **Allopalladium** | Pd |
| 25. **Iron** | Fe with Ni, Co, also Mn | | |
| Awaruite | $Fe Ni_2$ | | |
| Schreibersite, Rhabdite, etc. | | | |

---

## 1. Carbon Group.

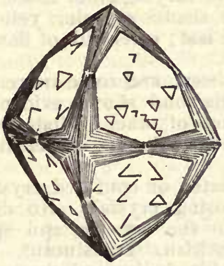
**1. DIAMOND.** Adamas, punctum lapidis pretiosior auro, *Manilius*, Astron., 4, l. 926 (the earliest distinct mention of true diamond). Adamas, in part, *Plin.*, 37, 15. Diamant *Germ.* Diamant *Fr.* Diamante *Ital.*, *Span.*

Isometric; tetrahedral. Observed forms[1]:

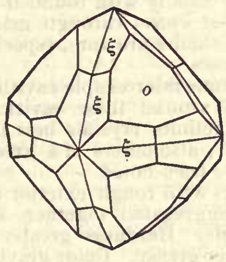
*a* (100, *i-i*)
*o* (111, 1)
*d* (110, *i*)
*f* (310, *i*-3)
*e* (210, *i*-2)
*g* (320, *i*-$\frac{3}{2}$)
ϑ (430, *i*-$\frac{4}{3}$)
λ (11·10·0, *i*-$\frac{11}{10}$)
*p* (221, 2)
φ (511, 5-5)
*n* (211, 2-2)
*s* (321, 3-$\frac{3}{2}$)
*u* (431, 4-$\frac{4}{3}$)
ξ (near *o*)
ϑ (near *d*)
Σ (541, 5-$\frac{5}{4}$)
Φ (651, 6-$\frac{6}{5}$)

No distinction can be made between the + and − tetrahedral forms, and the hemihedral character of the species has been questioned.

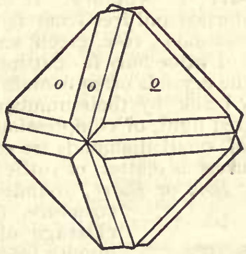
1.



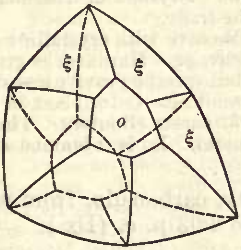
2.



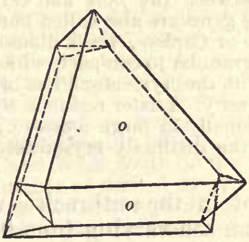
3.



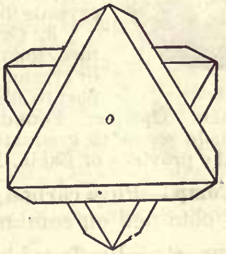
4.



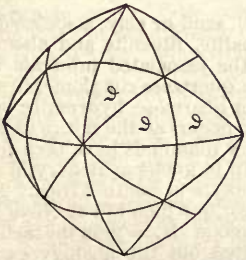
5.



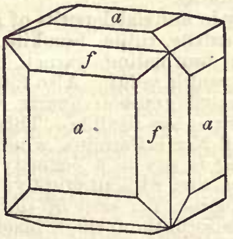
6.



7.



8.



9.

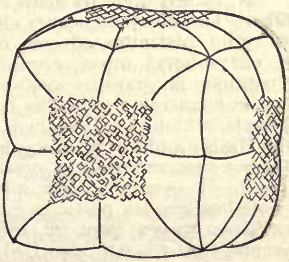


Fig. 1, S. Africa. 2, Haidinger. 3, 7, 8, Rose-Sadebeck. 9, Groth.

Twins: tw. pl. *o* very common, both contact- and penetration-twins; the former often flattened ∥ *o*; also tw. axis a cubic axis, the twins with parallel axes, symmetrical to a cubic plane, and interpenetrating each other. Faces commonly much curved, and often striated, most frequently ∥ intersection with *o*. Inverted triangular depressions common on *o* (f. 1), also others of diagonal quadrilateral form on *a*; octahedral faces built up of successive plates. Crystals distorted into elongated, pear-shaped forms, also irregular; and in groups. In spherical forms with radiated structure and rough exterior. Rarely massive.

Cleavage: *o* highly perfect. Fracture conchoidal. Brittle. H. = 10, but greater on *a* than on *o*. G. = 3·516 – 3·525 crystals; 3·499 – 3·503 bort; 3·15 – 3·29 carbonado, E. v. Baumhauer.[2] Luster adamantine to greasy, sometimes dull. Color white or colorless; occasionally various pale shades of yellow, red, orange, green, blue, brown; sometimes black. Usually transparent; also translucent and opaque. Refractive and dispersive power high; indices:

$$n_{\mathrm{r}} = 2{\cdot}4135 \qquad n_{\mathrm{y}} = 2{\cdot}4195 \qquad n_{\mathrm{gr}} = 2{\cdot}4278, \text{ Dx}^3.$$
$$n_{\mathrm{r}} = 2{\cdot}40845 \text{ Li} \qquad n_{\mathrm{y}} = 2{\cdot}41723 \text{ Na} \qquad n_{\mathrm{gr}} = 2{\cdot}42549 \text{ Tl, Schrauf}^4.$$

Becomes phosphorescent when exposed to light radiation or to an electric discharge in a vacuum tube. Positively electrified by friction; a non-conductor of electricity. Often shows abnormal double refraction, rarely distinctly uniaxial; also occasionally exhibits asterism.

**Var.**—1. *Ordinary.* In crystals usually with rounded faces and varying from those which are colorless and free from flaws (*first water*) through many faint shades of color, yellow the most common; rose, green, and blue shades are rare, especially the last; often full of flaws and hence of value only for cutting purposes.

The crystals often contain numerous microscopic cavities (Brewster), and some are rendered nearly black by their number; and around these cavities the diamond shows evidence, by polarized light, of compression. Sometimes crystals bear impressions of other crystals. Inclusions of small diamonds are common; also others of a green chloritic mineral, of hematite, of carbonaceous matter, of rutile (?) have been noted.

2. *Bort* or *Boort;* rounded forms with rough exterior and radiated or confused crystalline structure, often aggregated together, or enclosing crystals. No distinct cleavage obtainable. Hardness greater than in the crystals, and specific gravity less. Luster greasy. Color grayish to blackish. Translucent. There are gradual transitions from the perfectly crystallized diamond through the forms imperfectly crystallized or made up of several individuals to the true bort, as again between the bort and carbonado. Crystals or fragments of crystals useless as gems are also called bort in the trade.

10.

Bort.

3. *Carbonado* or *Carbon;* black diamond. Massive with crystalline structure, sometimes granular to compact, without cleavage. Hardness as great as, or greater than with the crystals and less brittle, but specific gravity less, due in part to slight porosity. Luster resinous to adamantine. Color black or grayish black. Opaque. Found occasionally in large masses up to 731 carats (Boutan). The true carbonado seems to graduate into the distinctly crystallized mineral. It is obtained chiefly from the province of Bahia, Brazil.

**Comp.**—Pure carbon, except in the anthracitic variety, carbonado, from which Rivot obtained on combustion an ash varying from 0·24 to 2·03 p. c. (Dx.).

**Pyr., etc.**—Unaffected by heat except at very high temperatures, when (in an oxygen atmosphere) it burns to carbon dioxide; out of contact with the air it is transformed into a kind of coke.[5] Not acted upon by acids or alkalies.

**Obs.**—The diamond occurs chiefly in alluvial deposits of gravel, sand or clay, associated with quartz, gold, platinum, zircon, octahedrite, rutile, brookite, hematite, ilmenite and also andalusite, chrysoberyl, topaz, corundum, tourmaline, garnet, etc.; the associated minerals being those common in granitic rocks or granitic veins. Also found in quartzose conglomerates, and further in connection with the laminated granular quartz rock or quartzose hydromica schist, *itacolumyte*, which in thin slabs is more or less flexible. This rock occurs at the mines of Brazil and the Urals; and also in Georgia and North Carolina, where a few diamonds have been found

It has been reported as occurring *in situ* in a pegmatyte vein in gneiss at Bellary in India (Chaper[7]). It occurs further in connection with an eruptive peridotyte in South Africa. It has been noted as grayish particles forming one per cent of the meteorite which fell at Novo-Urei, Govt. Pensa, Russia, Sept. 22, 1886; also in the form of black diamond (H. = 9) in the meteorite of Carcote, Chili[8]. (Cf also Cliftonite, p. 6.) Daubrée has pointed out the analogy existing between the occurrence of the diamond in South Africa (see below) and in meteorites, C. R., 110, 18, 1890.

India was the chief source of diamonds from very early times, as recorded by Sanskrit writers, down to the discovery of the Brazilian mines. There are three principal localities. The first in southern India, in the Madras presidency, embraces the districts of Kadapah (or Cuddapah), Bellary, Karnul, Kistna and Godavari. This region includes the famous "Golconda mines," the name, however, as stated by Ball, being to some extent a misnomer since it was merely the mart where the diamonds were bought and sold; it was originally applied to the capital now represented only by an abandoned fort near Hyderabad, and was thence extended to the surrounding district. A second region farther north covers a large tract between the Mahanadi and Godavari rivers; it includes the neighborhoods of Sambalpur and Wairagarh 80 miles southeast of Nagpur. Connected with this tract there are also two or three localities within the province of Chutia Nagpur, where diamonds have been found. A third region is in Bundelkhand, in central India, especially near the town of Panna. In addition to the preceding some diamonds have also been reported as obtained from a hill stream near Simla. The Indian diamonds were obtained in part from alluvial washings, in part from a quartzose conglomerate; at Panna this conglomerate (Rewah group) appears to be largely made up of fragments of a lower sandstone (Semri sandstone) which it has been suggested may represent the original matrix. The yield of the Indian mines, once so large, is now insignificant; it is mentioned, however, that one stone, weighing when rough 67 and as cut 25 carats, was found in 1881 in the Bellary district (Mallet).

The diamond deposits of Brazil have been worked since the early part of the 18th century, and have yielded very largely, although at the present time the amount obtained is small. The most important region was that near Diamantina in the province of Minas Geraes. It is situated along the crest and on the flanks of the Serro do Espinhaço, the mountain ridge which separates the São Francisco river and its branches, especially the Rio das Velhas on the west, from the Jequitinhonha, and the Doce on the east. The diamonds are obtained in part from river washings (*servicos do rio*), as conspicuously those of the bed of the Jequitinhonha, and in part from prairie washings (*servicos do campo*) as on the high ridge known as the heights of Curralinho. The river deposits (*cascalho*) consist of rolled quartz pebbles, mixed with or cemented by a ferruginous clay, which usually rests on a bed of clay. The most common associated minerals are rutile, octahedrite, brookite, hematite, martite, ilmenite and magnetite, with also quartz, cyanite, tourmaline, lazulite, gold, and many others as garnet, zircon, euclase, topaz, etc. The diamonds are most abundant in the *caldeiroes*, which seem to be large potholes or giant kettles. In the upper plateau diggings, the diamond occurs in part in a sort of conglomerate called the *gurgulho*, consisting of quartz fragments which are less rolled than those of the cascalho, as are also the accompanying minerals, which occur too in less abundance. At some of these mines, as those of São João da Chapada, the diamonds occur in clay (*barro*) which has been regarded as the result of the decomposition *in situ* of veins traversing the hydromica schist and itacolumyte formation. At Grão Mogor, farther north, diamonds have been obtained in the quartzose schist (called itacolumyte), though most of the specimens showing this association are fraudulent.

Other Brazilian localities are those of Bagagem and Abaethe, southwest of Diamantina; further the Lençåes and other mines of the province of Bahia, discovered in 1844, and finally on the Salobro and other branches of the Rio Pardo, two days' journey from the little port of Canavieiras, discovered in 1881.

The discovery of diamonds in South Africa dates from 1867. The diamonds occur in the gravel of the Vaal river, from Potchefstroom, capital of the Transvaal Republic, down to its junction with the Orange river, and thence along the latter stream as far as Hope Town. The principal *river diggings*, however, are along the Vaal river between Klip Drift and its junction with the Hart river. These have yielded well, including some large stones (as the "Stewart," and "Star of South Africa"), but are now comparatively unproductive, and have been nearly abandoned for the *dry diggings*, discovered in 1871.

These are chiefly in Griqualand-West, south of the Vaal river, on the border of the Orange Free State. There are here a number of limited areas approximately spherical or oval in form, with an average diameter of some 200 to 300 yards, of which Kimberley, De Beer's, Du Toit's Pan and Bultfontein are the most important. A circle 3½ miles in diameter encloses the four principal diamond mines.

The general structure is similar: a wall of nearly horizontal black carbonaceous shale with upturned edges enclosing the diamantiferous area. The upper portion of the deposit consists of a friable mass of little coherence of a pale yellow color, called the "yellow ground." Below the reach of atmospheric influences, the rock is more firm and of a bluish green or greenish color; it is called the "blue ground" or simply "the blue." This consists essentially of a serpentinous breccia: a base of hydrated magnesian silicate penetrated by calcite and opaline silica and enclosing fragments of bronzite, diallage, vaalite, also garnet, magnetite, and ilmenite, and less commonly smaragdite, pyrite, zircon, etc. The diamonds are rather abundantly disseminated through the mass, in some claims to the amount of 4 to 6 carats per cubic yard. The original rock seems to have been a peculiar type of peridotite which has been called *Kimberlyte.* These areas are believed to be volcanic pipes and the occurrence of the diamonds is obviously connected with the eruptive outflow, whether brought up from underlying rocks (as the large number of broken stones suggests) or formed by the action of heat upon the carbonaceous shales is uncertain.

Since the discovery of the South African mines in 1867, up to 1886, it has been estimated that the region has yielded stones aggregating upward of 30 million carats, of a value of from 200 to 250 million dollars; the yield for 1886 was over 3 million carats. (Jb. Min., **2**, 81, 1887.) Another estimate (1889) gives as the amount obtained from Kimberley's, De Beer's, Du Toit's Pan, and Bultfontein, between Sept. 1882 and the end of 1888, 18 million carats valued at nearly 100 million dollars; further, the entire production of the 18 years (1871–1889 incl.) is estimated as exceeding 40 million carats, or more than *eight tons*. The single mine of Kimberley is said to have yielded from 1871 to the end of 1885 about 17½ million carats (3½ tons), while the total amount of reef and ground excavated exceeded 20 million tons. (J. Soc. Arts, Oct. 4, 1889.) In 1889 the yield is stated to have been 3 million carats valued at over 20 million dollars.

Diamonds are also obtained in some quantity in Borneo, associated with platinum, etc.: thus on the west in the basin of the Kapoeas river near the town of Pontianak, and also in the southeast near Bandjermassim. In Australia, in alluvial deposits near Mudgee on the Cudgegong river and Bingera in the valley of the Horton river in New South Wales. Other localities, chiefly in connection with gold-washings, have been noted in Victoria, Queensland, and South Australia.

The Ural diamonds were discovered in 1829; they occur in the detritus along the Adolfskoi rivulet near Bisersk, where worked for gold, and also at other places.

In the United States a few crystals have been met with in Rutherford Co., N. C., and Hall Co., Ga.; they occur also at Portis mine, Franklin Co., N. C. (Genth); one handsome one, over ¾ in. in diameter, in the village of Manchester, opposite Richmond, Va.; one weighing 4⅓ carats was found in 1886 at Dysortville, McDowell Co., N. C.

In California, at Cherokee ravine, in Butte Co.; also in N. San Juan, Nevada Co.; in French Corral, one of 1⅛ carats; at Forest Hill, El Dorado Co., of 1½ carats; Fiddletown, Amador Co.; near Placerville. Reported from Idaho and from Oregon with platinum.

The largest diamond of which we have any knowledge is mentioned by Tavernier (1676) as in possession of the Great Mogul. As figured by him it had the form and size of half a hen's egg. It is stated to have weighed originally 790 carats, but there is some question as to this amount, and it may have been much less. Some authors believe that the Kohinoor is identical with this diamond, perhaps reduced in size by cleavage.* The Kohinoor weighed when brought to England 186 carats, and as recut as a brilliant, it weighs now 106 carats. Other famous diamonds are: the Orlov, 193 carats; the Regent or Pitt, 137 carats; the Florentine or Grand Duke of Tuscany, 133 carats; the Sancy, 53 carats. The "Star of the South," found in Brazil in 1853, weighed before and after cutting respectively 254 and 125 carats. Also famous because of the rarity of their color are the green diamond of Dresden, 40 carats, and the deep blue Hope diamond from India, weighing 44 carats. The history of the above stones and of others is given in many works on gems.

Of more recent stones from South Africa may be mentioned: The Victoria (or the Imperial) from one of the Kimberley mines, which weighed as found 457 carats; it was reduced to 230 carats by cutting, and later was recut; is now said to be a perfect brilliant of 180 carats. The Stewart weighed before and after cutting 288 and 120 carats respectively; the Star of South Africa, 83 and 46 carats. The Tiffany diamond, of a brilliant golden yellow, weighs, cut as a double brilliant, 125 carats. The colorless Porter Rhodes diamond, found at Kimberley in 1880, weighed 150 carats uncut. The Julius Pam diamond, 241½ carats (uncut) was found at the new Jagerfonstein United mine in 1889.

**Artif.**—Repeated attempts to form the diamond artificially have been unsuccessful; further, its method of formation in nature is a matter of vague hypothesis and speculation.

**Ref.**—[1] See the monograph of Rose-Sadebeck, Abh. Ak. Berlin, 1876; Zs. G. Ges., **30**, 605, 1878. Some of these planes (e.g., $\vartheta$, $\lambda$, $u$, $\Sigma$) must be regarded as doubtful because of their rounded faces. Cf. also Hirschwald, Zs. Kr., **1**, 212, 1877; Groth, Min. Samml. Strassb., 4, 1878.

S. W., 116, 1888. *United States*, Kunz, Gems and Precious Stones of North America, 1890.

[8] Diamond in meteorites, Erofeyev and Lachinov, Vh. Min. Ges., **24**, 263, 1884; Sandb., Jb. Min., **2**, 173, 1889; Will and Pinnow, Ber. Ch. Ges., **23**, 345, 1890.

The general literature contains such books as the Edelsteinkunde of Klüge (1871), Schrauf (1869), Groth (1887); Burnham on Precious Stones (Boston, 1886). A good summary of all points in regard to the diamond is given by M. E. Boutan, Le Diamant, Paris, 1886, 323 pp., with numerous plates, etc.; pp. 312–320 give a very *full bibliography*.

CLIFTONITE. *Fletcher*, Min. Mag., **7**, 121, 1887.

In minute cubic crystals, sometimes with dodecahedral faces, or with those of a low tetra-

---

* A discussion of this subject is given in Ball's Translation of Tavernier's Travels in India, London, 1889.

hexahedron. No cleavage. Faces often depressed. H. = 2·5. G. = 2·12. Color and streak black. Comp.—Carbon, like graphite, with which it agrees in characters except form and hardness. From the Youndegin, West Australia, meteoric iron, found in 1884. Named after R. B. Clifton, Professor of Physics at Oxford, England. Graphitic crystals, of cubo-octahedral form, occur in the Cocke Co., Tenn. (Sevier) iron.

Haidinger (Pogg., **67**, 437, 1846) described graphite crystals from the Magura, Arva meteorite, regarded by him as pseudomorphs after pyrite, but suggested by Rose to be pseudomorph after diamond, Beschr. Meteor., 40, 1864. Brezina has studied the Arva crystals further, identifying the forms (310, 320); he shows that they and the cliftonite are to be regarded as pseudomorphs after diamond, Ann. Mus. Wien, **4**, 102, 1889.

**2. GRAPHITE.** Plumbago, Molybdæna, Bly-Ertz, *Bromell*, Min., 58, 1739 [not Plumbago *Agric.*, *Gesner*]. Blyertz pt., Mica pictoria nigra, Molybdæna pt., *Wall.*, 131, 1747. Mica des Peintres, Crayon, *Fr. Trl.* Wall., 1753. Black Lead. Reissblei (= Drawing-lead) *Germ.* Molybdænum *Linn.*, 1768. Plumbago *Scheele* (proving its carbon nature), Ak. H. Stockholm, 1779. Plombagine *de Lisle*, Crist., 1783. Graphit *Wern.*, Bergm. J., 380, 1789, *Karst.*, Mus. Lesk., **2**, 339, 1789. Melangraphit *Haid.*, Handb., 513, 1845. Fer carburé *Fr.* Grafite, Pombaggine *Ital.* Grafita *Span.*

Rhombohedral. Axis $\dot{c} = 1{\cdot}3859$; $0001 \wedge 10\bar{1}1 = {}^*58°$ Kenngott[1].

**Forms**[2]: *c* (0001, *O*); *a* $(11\bar{2}0, i\text{-}2)$; *r* $(10\bar{1}1, R)$; *t* $(22\bar{4}6, \frac{2}{3}\text{-}2)$; *s* $(11\bar{2}1, 2\text{-}2)$. Angles: *ct* = 42° 44′; *cs* = 70° 10′; *rr′* = 94° 31′.

In six-sided tabular crystals striated ‖ edge *c/r*, faces rarely distinct. Commonly in imbedded foliated masses, also columnar or radiated; scaly or slaty; granular to compact; earthy. Rarely in globular concretions with radiated structure.

Cleavage: basal, perfect, *r* indistinct(?). Thin laminæ flexible, inelastic. Feel greasy. H. = 1–2. G. = 2·09–2·23; 2·229 Kenng. Luster metallic, sometimes dull, earthy. Color iron-black to dark steel-gray. Opaque. A conductor of electricity.

**Comp.**—Carbon, like the diamond; often impure from the presence of iron sesquioxide, clay, etc.

The purest forms usually yield upon combustion a little ash, from a fraction of one per cent upwards (see 5th Ed. p. 24). The specific gravity varies with the amount of impurities. Rammelsberg obtained as the residue upon ignition of purified graphite: Ticonderoga 0·24 p. c., Siberia (Alibert) 0·60, Arendal 0·64, Upernavik 1·97. Min. Ch., 1, 1875.

**Pyr., etc.**—At a high temperature some graphite burns more easily than diamond, other varieties (e.g. Ticonderoga) much less so (Rose, cf. Rg. l. c.). B.B. infusible; fused with nitre in a platinum spoon, deflagrates, converting the reagent into potassium carbonate, which effervesces with acids. Unaltered by acids.

**Obs.**—Graphite occurs in beds and embedded masses, laminæ, or scales, in granite, gneiss, mica schist, crystalline limestone. It is in some places a result of the alteration by heat of the coal of the coal formation. Sometimes met with in basaltic rocks, as with the metallic iron of Ovifak, Greenland. It is often observed in meteoric irons[3], either in nodules or in veins; the Sevier iron yielded a nodule weighing 92 grams. Cf. also Cliftonite.

A fine variety of graphite occurs at Borrowdale in Cumberland, in nests in trap, which occurs in clay slate; in Glenstrathfarrar in Inverness-shire, forms nests in gneiss; at Arendal in Norway, in quartz; at Pargas in Finland; in the Urals, Siberia, Finland; in various parts of Austria; at Passau in Bavaria; France; at Craigman, Ayrshire, it occurs in coal-beds which have been altered by contact with trap. In Irkutsk, in the Tunkinsk Mts., in eastern Siberia, the Alibert graphite mine affords some of the best graphite of the world and in large quantities (Kk. Min., **4**, 158, 1862). Large quantities are brought from the East Indies, especially from Ceylon.

Forms beds in gneiss, at Sturbridge, Mass.; also at North Brookfield, Brimfield, and Hinsdale, Mass.; in Cornwall, near the Housatonic, and in Ashford, Conn.; at Goshen, Sullivan Co., N. H.; also in Brandon, Vt.; at Grenville, Pr. Q., associated with titanite and wollastonite in granular limestone. Foliated graphite occurs in large quantities at Ticonderoga, on Lake George; also upon Roger's Rock, associated with pyroxene and titanite. Near Amity, Orange Co., N. Y., it is met with in white limestone, accompanying spinel, chondrodite, hornblende, etc.; at Rossie, St. Lawrence Co., N. Y., crystallized with iron ore, and in gneiss; at Hillsdale, Columbia Co., N. Y.; at Bloomingdale, N. J.; at Franklin, N. J., in rounded concretions radiated within; in Loudon Co., Va.; in Wake Co., N. C.; on Tiger River, and at Spartanburgh near the Cowpens Furnace, S. C.; also in Bucks Co., Penn., three miles from Attleboro', associated with wollastonite, pyroxene, and scapolite; and one and a half miles from this locality, it occurs in abundance in syenite, at Mansell's black-lead mine; also at Byers, Chester Co. A graphitic earth is mined for paint in Garland, Montgomery, Hot Spring and Polk Cos., Arkansas.

In California, at Sonora, Tuolumne Co., a deposit was formerly worked; occurs also at

Summit City, Alpine Co., near Fort Tejon, Kern Co., Tejunga, Los Angeles Co., Boser Hill, Fresno Co., and elsewhere. In Humboldt Co., Nevada; Beaver Co., Utah; Albany Co., Wyoming. A large deposit occurs at St. John, New Brunswick.

In the United States, the mines of Ticonderoga furnish most of the graphite mined commercially; 550,000 lbs were produced in 1883, 415,500 in 1886, 328,000 in 1887; also the Heron mine near Raleigh, N. C.. yielded 20,000 lbs. in 1887.

The name *black lead,* applied to this species, is inappropriate, as it contains no lead. The name graphite, of Werner, is derived from *γραφειν, to write.*

Artif.—A common product in iron furnaces.

Ref.—[1] Ticonderoga, Min. Not., xiv. 10; Ber. Ak. Wien, **13**, 1854. Nordenskiöld made the graphite from Ersby and Storgård monoclinic, Pogg., **96**, 110, 1855. The author's observations on Ticonderoga crystals confirm Kenngott. Hj. Sjögren has shown that the species must be regarded as hexagonal, Öfv. Ak. Stockh., **41**, No. 4, 29, 1884. [2] Cf. Kenng., l. c.—some doubt surrounds the measurements and planes because of the extraordinary flexibility of the material. Cf. Dx., Min., **2**, 23, 1874. [3] Meunier, Ann. Ch. Phys., **17**, 46, 1869; J. L Smith, Am. J. Sc., **11**, 388. 433, 1876.

**Tremenheerite**, *Piddington* Appears to be impure graphite, or is between coal and graphite; it is scaly in structure, and highly metallic in luster. Sent from Tenasserim by Capt. Tremenheere. Cf. Mallet, Min. India, p. 11, 1887.

**Graphitoid** from the mica schists and phyllytes of the Saxon Erzgebirge, is a form of combustible carbon, burning in the flame of a Bunsen burner. Analysis: C 99·76, H 0·24 = 100. Occurs as an incrustation, also impregnates the rock mass in fine bands. *Sauer*, Zs. G. Ges., **37**, 441, 1885.

**Schungite**, from the Olonets Government, Russia, is a similar amorphous form of carbon intermediate between anthracite and graphite, occurring in phyllite. Named (1884) from the locality Schunga. G. = 1·98. Contains 0·40 p. c. hydrogen. *Inostrantzev*, Jb. Min., **1**, 97, 1880; **1**, 92, 1886.

$$2H_{a.bl} = 106^\circ\ 16' \quad \beta_{bl} = 2{\cdot}082 \quad \therefore 2V_{bl} = 69^\circ\ 13'$$

Refractive indices, Schrauf[9]:

$$\text{Na (D line)} \qquad \alpha = 1{\cdot}95047 \qquad \beta = 2{\cdot}03832 \qquad \gamma = 2{\cdot}24052$$

**Comp., Var.**—Pure sulphur; often contaminated with clay, bitumen, and other impurities.

Sometimes contains traces of Te, Se, etc.; an orange-red variety from Japan (*tellursulphur*, H. Carvill Lewis) gave Divers (Ch. News, 48, 284, 1883) S 99·76, Te 0·17, Se 0·06, As 0·01 = 100.

Sulphur may also be obtained in the laboratory in other allotropic forms, see below.

**Pyr., etc.**—Melts at 108° C., and at 270° burns with a bluish flame yielding sulphur dioxide. Insoluble in water, and not acted on by the acids, but soluble in carbon disulphide.

**Obs.**—The great repositories of sulphur are either beds of gypsum and the associate rocks, or the regions of active and extinct volcanoes. In the valley of Noto and Mazzaro, in Sicily; at Conil, near Cadiz, in Spain; Bex, in Switzerland; Cracow, in Poland, it occurs in the former situation; near Bologna, Italy, in fine crystals, embedded in bitumen. Sicily and the neighboring volcanic isles; the Solfatara, near Naples; the volcanoes of the Pacific ocean, *e.g.*, Kilauea on Hawaii, etc., are localities of the latter kind. The crystals from Girgenti in Sicily are sometimes two or three inches in diameter. It is also deposited from hot springs in Iceland; and in Savoy, Switzerland, Hanover, and other countries, it is met with in certain metallic veins; with lead ores near Müsen and similarly at Monte Poni, Sardinia. Near Cracow and in Upper Egypt there are large deposits, and in the island of Melos. Abundant in the Chilian Andes: also obtained from China, Japan, India, the Philippine islands, etc.

Sulphur is found near the sulphur springs of New York, Virginia, etc., sparingly; in many coal deposits and elsewhere, where pyrites is undergoing decomposition; in microscopic crystals at some of the gold mines of Virginia and North Carolina; in minute crystals on cleavage surfaces of galena, Wheatley mine, Phenixville, Pa.; in small masses in limestone on the Potomac, twenty-five miles above Washington; in an extensive bed at Lake Charles, Calcasieu parish, La.; Tom Green Co., Texas.

Some of the more important deposits in the western U. S. are the following: in Wyoming, in the Uintah Mts., 30 miles s.e. of Evanston; in Nevada near Humboldt House, Humboldt county; also in the same county at the Rabbit Hole Springs; Steamboat Springs, Washoe Co.; Columbus, Esmeralda Co. In southern Utah in large deposits, now mined, at Cove Creek, Millard county. In California, at the geysers of Napa valley, Sonoma Co.; in Santa Barbara in good crystals; near Clear lake, Lake Co., a large deposit, with a vein of cinnabar cutting through it. In the Yellowstone Park, in deposits and about the fumaroles

**Artif.**—Sulphur may also be obtained in the laboratory in several other allotropic forms. As given by Muthmann[11] they are as follows:

| | | à : b̄ : ċ | |
|---|---|---|---|
| *β-sulphur* | Monoclinic | 0·99575 : 1 : 0·99983 | β = 84° 14′ |
| *γ-sulphur* | " | 1·06094 : 1 : 0·70944 | β = 88° 13′ |
| *δ-sulphur* | " | ? | |
| *ε-sulphur* | Rhombohedral? | | |

*β*-sulphur is obtained from fusion in prismatic crystals, often acicular or flattened ‖ 100, with 100, 110, 210, 011, 111, 111; 110 ∧ 110 = 86° 28′. This form was early studied by Mitscherlich.[10]

*γ*-sulphur is obtained from fusion, also by separation by chemical means from hot saturated solutions of various compounds; habit thin tabular ‖ 010, with 100, 210, 012, 111, 1̄11.

*δ*-sulphur obtained, but with difficulty, by separation by chemical means at low temperatures in thin pseudo-hexagonal plates.

*ε*-sulphur is the black sulphur (schwarze Schwefel of Magnus) which, it has been suggested, may belong in the group with metallic selenium and tellurium. Sulphur is also obtained in an elastic rubber-like form when poured in the molten condition into water; this soon, however, becomes brittle.

**Ref.**—[1] Min. Russl., **6**, 368, 1874, on crystals from Germany, Spain, and Lower Egypt. Zepharovich obtained identical results on crystals from Swoszowice, Jb. G. Reichs., **19**, 225, 1869. Accurate measurements, showing some variation in the form, especially between natural and artificial crystals, have also been made by Mitscherlich, Ann. Ch. Phys., **24**, 264, 1823, and l. c. below; Scacchi, Mem. G. Campania, 1849; Schrauf. Ber. Ak. Wien, **41**, 794, 1860; Brezina, ib., **60** (1), 539, 1870; Arzruni, Zs. Kr., **8**, 338, 1884; Molengraaff, ib., **14**, 43, 1888; Busz, ib., **15**, 616, 1889.

[2] See Brezina, l. c., for early authorities; he adds *ω*, *q*, *r*, *l* on artif. cryst. [3] Friedländer, Min.-Samml. Strassburg, p. 262, 1878. [4] Fletcher, Phil. Mag., **9**, 186, 1880. [5] E. S. D., Rabbit Hole, Nev., Am. J. Sc., **32**, 389, 1886. [6] Molengraaff, Saba, W. I., l. c. [7] Cf. Rath, Pogg., Erg., **6**, 349, 1873; **155**, 41, 1875. [8] N. R., 93, 1867. [9] l. c. [10] Abh. Ak. Berlin, June 26, 1823. [11] Zs. Kr., **17**, 336, 1890; cf. also Rg., Kr. Ch., 45, 1881.

### 4. SELENSULPHUR.

Schwefelselen *Stromeyer*, Schw. J., **43**, 452, 1825. Selenschwefel. Volcanite *Adam*, Tabl. Min., 54, 1869. Eolide *Bombicci*, Min., **2**, 186, 1875.

An orange-red or reddish brownish mineral containing sulphur and selenium, but in unknown proportions; occurs in crusts with sal ammoniac on the islands Vulcano and Lipari. A seleniferous sulphur occurs at Kilauea (J. D. D.), also in Japan.

In the laboratory mixtures of sulphur and selenium have been obtained in crystallized form. Muthmann[1] concludes that up to 35 p. c. of Se, the form corresponds to the orthorhombic *α*-sulphur; between 35 and 66 p. c. to *γ*-sulphur; more than 66 p. c. to *α*-selenium, which, it is suggested, may correspond to *δ*-sulphur. Cf. sulphur and selenium.

**Ref.**—[1] Zs. Kr., **17**, 357, 1890, also earlier; Rathke, Lieb. Ann., **152**, 188, 1869, and Bettendorff and Rath, Pogg., **139**, 329, 1870.

### 5. SELENIUM.

Selen *Germ.* Selenio *Ital.*

Del Rio has stated that a mineral from Culebras, Mexico, which he first announced as selenide of mercury and zinc (riolite of Brooke), was later found by him to be a mixture of *native selenium* with selenides of mercury, etc. No confidence, however, can be attached to this conclusion. Cf. Phil. Mag., **4**, 113, 1828; **8**, 261, 1836.

In the laboratory selenium can be obtained in several allotropic forms. As given by Muthmann, they are:

| | | à : b : ċ | |
|---|---|---|---|
| *α-selenium* | Monoclinic | 1·63495 : 1 : 1·6095 | β = 75° 58′ |
| *β-selenium* | " | 1·5916 : 1 : 1·1352 | β = 86° 56′ |
| *γ-selenium* | Rhombohedral | | |

*α*-selenium is obtained from hot saturated solutions in carbon disulphide, crystals thin tabular ‖ 001, of hexagonal habit.

*β*-selenium is obtained by the evaporation of cold saturated solutions in carbon disulphide in short thick prisms, also tabular ‖ 100 and ‖ 001; this form was earlier measured by Mitscherlich.

*γ*-selenium or metallic selenium is rhombohedral, isomorphous with tellurium and occurs of similar habit. G. = 4·5. It is a conductor of electricity, but its resistance varies widely under the action of light.

It has been assumed that the monoclinic selenium of Mitscherlich was isomorphous with the early known monoclinic sulphur (Rg., Kr. Ch., 47, 65, 1881), but Muthmann's measurements fail to show any close resemblance in angle.

## 3. Tellurium-Arsenic Group.

**6. SELEN-TELLURIUM.** *E. S. Dana* and *H. L. Wells*, Am. J. Sc., **40**, 78, 1890.

Massive, with indistinct columnar structure.

Cleavage: hexagonal prismatic perfect. Brittle. H. = 2–2·5. Luster metallic. Color blackish gray. Streak black. Opaque.

**Comp.**—Tellurium and selenium in a ratio of nearly 3 : 2.

**Anal.**—H. L. Wells, after deducting 65·68 p. c. gangue, consisting largely of quartz with some barite:

Te 70·69 Se 29·31 = 100

**Pyr., etc.**—B.B. on charcoal fuses very easily, coloring the flame blue with a greenish tinge, and giving a strong characteristic odor of selenium; the sublimate near the assay is white, and dull reddish at a distance. In the closed tube a nearly black sublimate with a reddish edge above (Se), and below drops with metallic luster (Te). In the open tube a grayish sublimate with a reddish fringe, and above this volatile crystals of $SeO_2$; and below near the assay a copious sublimate of $TeO_2$, fusing into colorless drops.

**Obs.**—Occurs embedded in a gangue consisting largely of quartz with some barite at the El Plomo silver mine, Ojojona district, Tegucigalpa, Honduras.

**7. TELLURIUM.** Aurum paradoxum vel problematicum *Müller v. Reichenstein*, Phys. Arb., Wien, **1**, 1782. Sylvanite *Kirwan*, Min., **2**, 324, 1796. Gediegen-Tellur *Klapr.*, Beitr., **3**, 2, 1802. Tellur, Gediegen Sylvan *Germ.* Tellure natif auro-ferrifère *H.* Tellurio *Ital.*

Rhombohedral. Axis $\dot{c}$ = 1·3298; 0001 ∧ $10\bar{1}1$ = *56° 55½′ Rose[1].

**Forms:** *c* (0001, *O*); *m* ($10\bar{1}0$, *I*); *r* ($10\bar{1}1$, *R*); $r_1$ ($01\bar{1}1$, −1). Angles: $rr'$ = 93° 3′, $rr_1$ = 49° 32.

Crystals minute hexagonal prisms with *r*, or both *r* and *r*, and then hexagonal in aspect. Commonly massive, columnar to fine granular.

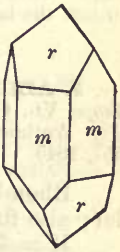
Cleavage: *m* perfect; *c* imperfect. Somewhat brittle. H. = 2–2·5. G. = 6·1–6·3. Luster metallic. Color and streak tin-white.

**Comp.**—Tellurium, with sometimes a little selenium, also gold, iron, etc. A specimen from Nagyág afforded Petz (Pogg., **57**, 477, 1842): Tellurium 97·215, and gold 2·785, with a trace of iron and sulphur. Another from Fačzebaja gave von Foullon: Te 93·31, Se 6·69 = 100, after deducting pyrite 12·40 p. c., quartz 1·10, Vh. G. Reichs., 269, 1884.

**Pyr.**—In the open tube fuses, giving a white sublimate of tellurium dioxide, which B. B. fuses to colorless transparent drops. On charcoal fuses, volatilizes almost entirely, tingeing the flame green, and giving a white coating.

**Obs.**—Occurs at the mine of Maria Loretto, near Zalathna, in Transylvania (whence the name *Sylvan* and *Sylvanite*), in sandstone, accompanying quartz, pyrite, and gold. In Boulder county, Colorado, at the Red Cloud mine; also in Magnolia district at the Keystone, Dun Raven, and other mines; in the Ballerat district at the Smuggler mine; in Central district at the John Jay mine in large masses. An impure variety from the Mountain Lion mine has been called *Lionite* (Berdell).

1.



Artif. cryst.

**Ref.**—[1] Rose, Abh. Ak. Berlin, 84, 1849; also on artif. cryst., *s* ($11\bar{2}1$ 2-2). Penfield obtained on brilliant artif. crystals, $rr'$ = 93° 10′ (priv. contr.); von Foullon, on Fačzebaja crystals, $mr$ = 33° 6′ (l. c.).

**8. ARSENIC.** Gediegen Arsenik, Arsen, Scherbenkobalt, *Germ.* Arsenic natif *Fr.* Arsenico nativo *Ital.*, *Span.*

Rhombohedral. Axis $\dot{c}$ = 1·4013; 0001 ∧ $10\bar{1}1$ = 58° 17′ Zepharovich[1].

**Forms:** *r* ($10\bar{1}1$, *R*); also artif. cryst., *c* (0001, *O*); *z* ($10\bar{1}4$, + ¼); *e* ($01\bar{1}2$, − ½); *h* ($03\bar{3}2$, − $\frac{3}{2}$). Angles: $rr'$ = *94° 54′, $cz$ = 22° 1½′, $ce$ = 38° 58½′, $ch$ = 67° 36′, $zz'$ = 37° 54′, $ee'$ = 66° 0½′.

Twins: tw. plane *e*. Natural crystals rare, usually acicular. Generally granular massive; sometimes reticulated, reniform, and stalactitic (Scherbenkobalt *Germ.*). Structure rarely columnar.

Cleavage: *c* highly perfect; *e* imperfect. Fracture uneven and fine granular. Brittle. H. = 3·5. G. = 5·63–5·73. Luster nearly metallic, Color and streak tin-white, tarnishing soon to dark gray.

**Comp.**—Arsenic, often with some antimony, and traces of iron, silver, gold, or bismuth.

Anal. Janovsky (Ber. Ak. Wien, **71** (1), 276, 1875) from Joachimsthal: As 90·91, Sb 1·56, Ni 4·64, Fe 2·07, $SiO_2$ 0·55, Mn, S *tr.* = 99·73. A variety from Valtellina, with G. = 5·777, contained 8·3 to 10·8 p. c. Sb, Bizzarri and Campani, Zs. Kr., **12**, 194, 1886.

**Pyr.**—B.B. on charcoal volatilizes without fusing, coats the coal with white arsenic trioxide, and affords a garlic odor; the coating treated in R. F. volatilizes, tingeing the flame blue.

**Obs.**—Native arsenic commonly occurs in veins in crystalline rocks and the older schists, and is often accompanied by ores of antimony, ruby silver, realgar, sphalerite, and other metallic minerals.

The silver mines of Freiberg, Annaberg, Marienberg, and Schneeberg afford it in considerable quantities; also Joachimsthal in Bohemia, Andreasberg in the Harz, Kapnik and Orawitza in Hungary, Kongsberg in Norway, Zmeov in Siberia in large masses, and at St. Maria aux Mines in Alsace; also Mt. Corna dei Darden, Valtellina, Italy. Abundant at the silver mines at Chañarçillo, and elsewhere in Chili; at the argentiferous mines of San Augustin, Hidalgo, Mexico, and Kapanga gold mine, New Zealand.

In the U. S. at Haverhill, N. H., in thin layers in dark-blue mica slate; also at Jackson, N. H.; on the E. flank of Furlong Mtn., Greenwood, Me. In nodules in a silver and gold mine near Leadville, Colorado. Watson Creek, Fraser R., British Columbia.

The name arsenic is derived from the Greek ἀρρενικόν or ἀρσενικόν, *masculine*, a term applied to orpiment or sulphide of arsenic, on account of its potent properties.

**Alt.**—Oxidizes on exposure, producing a black crust, which is a mixture of arsenic and arsenolite ($As_2O_3$), also producing pure arsenolite.

**Ref.**—[1] Joachimsthal, Ber. Ak. Wien, **71** (1), 272, 1875. Rose gives for artif. crystals, *rr'* = 94° 56′, Abh. Ak. Berlin, 82, 1849; Miller gives *rr'* = 94° 19′, Min. p. 117, 1852.

ARSENOLAMPRITE.—*C. Hintze*, Zs. Kr., **11**, 606, 1886. Arsenik-wismuth, *Werner;* arsenglanz, hypotyphit, *Breithaupt*.

Apparently an allotropic form of arsenic. Massive, with fibrous foliated structure, showing one cleavage. H. = 2. G. = 5·3–5·5. Luster metallic, brilliant. Color lead-gray. Streak black. Composition, nearly pure arsenic. Werner's mineral contained 3 p. c. bismuth; a specimen examined by Frenzel (Jb. Min., 677, 1874) gave: As 95·86, Bi 1·61, Fe 1·01, S 0·99 = 99·47. The original *arsenglanz* is from Marienberg, Saxony; also reported from Markirch in Alsace. Hintze obtained: As 98·43, Fe 1·00, $SiO_2$ 0·05; his mineral was from Copiapo, Chili. Differs from ordinary arsenic in structure, softness, lower specific gravity and brilliant luster; the last character suggests the name from λαμπρός *lustrous*.

**9. ALLEMONTITE.** Antimoine natif arsenifère *H.*, Tr. **4**, 281, 1822. Arsenikspiessglanz *Zippe*, Vh. Ges. Mus. Böhmen, 1824, 102. Arsenik-Antimon *Hausm.* Arseniure d'Antimoine *Fr.* Antimon-Arsen, Arsenantimon, *Germ.* Arsenical Antimony. Allemontit, *Haid.*, Handb., 557, 1845

Rhombohedral. In reniform masses and amorphous; structure curved lamellar; also fine granular.

H = 3·5. G. = 6·203, Rg. Luster metallic, occasionally splendent; sometimes dull. Color tin-white or reddish gray; often tarnished brownish black.

**Comp.**—$SbAs^3$ = Arsenic 65·2, antimony 34·8.

Analysis, Rg. (Pogg., **62**, 137, 1844), Allemont: Arsenic [62·15], antimony 37·85 = 100.

**Pyr.**—B.B. emits fumes of arsenic and antimony, and fuses to a metallic globule, which takes fire and burns away, leaving antimony trioxide on the charcoal.

**Obs.**—Occurs sparingly at Allemont; Přibram in Bohemia, associated with sphalerite, antimony, siderite, etc.; Schladming in Styria; Andreasberg in the Harz.

ANTIMONIAL ARSENIC.—An antimonial arsenic, containing, according to Schultz (Rg., Min. Ch., 984, 1860), 7·97 p. c. of antimony, occurs at the Palmbaum mine, near Marienberg in Saxony. A similar compound, consisting, according to Genth (Am. J. Sc., 33, 191, 1862), of arsenic 90·82 and antimony 9·18 (= 17 As + 1 Sb), occurs at the Ophir mine, Washoe Co., California, in finely crystalline, and somewhat radiated, reniform masses, between tin-white and iron-black on a fresh fracture, but grayish black on tarnishing, associated with arsenolite, calcite, and quartz.

**10. ANTIMONY.** Gediget Spitsglas (fr. Sahlberg) *v. Swab.*, Ak. H. Stockh., **10**, 100, 1748, *Cronst.*, Min., 201, 1758. Spiesglas, Gediegen Antimon *Germ.* Antimoine natif *Fr.* Antimonio nativo *Ital.*, *Span.*

Rhombohedral. Axis $\dot{c}$ = 1·32362; 0001 ∧ $10\bar{1}1$ = 56° 48′ 12″ Laspeyres'.

**Forms**[2]: *c* (0001, *O*); *r* (1011, *R*), *z* ($10\bar{1}4$, $+\frac{1}{4}$); *e* (0112, $-\frac{1}{2}$); also on artif. crystals[3] *a* ($11\bar{2}0$, *i*-2;, *s* ($02\bar{2}1$, − 2), *x* ($23\bar{5}8$, $-\frac{1^5}{8}$).

$cz = 20° 55'$ $ce = 37° 23'$ $zz' = 36° 1'$ $ee' = 63° 27'$

$cr = 56° 48'$ $cs = 71° 53'$ $rr' = {}^*92° 53' 10''$ $ss' = 110° 47\frac{1}{2}'$.

Twins[4]: tw plane *e*, in complex groups, fourlings and sixlings, also polysynthetic. Generally massive, lamellar and distinctly cleavable; also radiated; sometimes botryoidal or reniform with a granular texture.

Cleavage[3]: *c* highly perfect; *e* distinct; *s* sometimes distinct; *a* indistinct. Fracture uneven; very brittle. H. = 3–3·5. G. = 6·65–6·72. Luster metallic. Color and streak tin-white.

**Comp.**—Antimony, containing sometimes silver, iron, or arsenic.

**Pyr.**—B.B. on charcoal fuses, gives a white coating in both O. F. and R. F.; if the blowing be intermitted, the globule continues to glow, giving off white fumes, until it is finally crusted over with prismatic crystals of antimony trioxide. The white coating tinges the R. F. bluish green. Crystallizes readily from fusion.

Occurs in lamellar concretions in granular limestone near Sala in Sweden; at Andreasberg in the Harz; in argentiferous veins in gneiss at Allemont in Dauphiné; at Přibram in Bohemia; in Mexico; Huasco, Chili; Sarawak in Borneo; at Warren, N. J.; in Kern Co., Cal., between Kernville and Havilah; in argillyte at South Ham, Canada; in considerable quantities at Prince William parish, York Co., N. Brunswick, cf. Kunz, Am. J. Sc., **30**, 275, 1885.

**Alt.**—Oxidizes on exposure and forms valentinite ($Sb_2O_3$).

**Ref.**—[1] On artif. cryst., Zs. G. Ges., **27**, 574, 1875; Rose obtained $rr' = 92° 25'$ and $\dot{c} = 1·3068$, Abh. Ak. Berlin, 73, 1849. [2] Andreasberg, described by Römer, Jb. Min., 310, 1848, but shown by Rose to be complex twins, with tw. plane *e*. [3] Lasp. l. c. [4] Lasp. l. c., also Mgg., Jb. Min., **2**, 40, 1884, **1**, 183, 1886.

**11. BISMUTH.** Bisemutum, Plumbum cinereum, *Agric.*, Foss., 439, Interpr. 467. Antimonium femininum, Tectum Argenti, *Alchem.* Gediegen Wismuth *Germ.* Bismuth natif *Fr.* Bismuto nativo *Ital,, Span.*

Rhombohedral. Axis $\dot{c} = 1·3036$; $0001 \wedge 10\bar{1}1 = 56° 24\frac{1}{6}'$ Rose[1].

**Forms**[1]: *c* (0001, *O*); *r* ($10\bar{1}1$, *R*); *e* ($01\bar{1}2$, $-\frac{1}{2}$), *g* ($04\bar{4}5$, $-\frac{4}{5}$)[2], *s* ($02\bar{2}1$, − 2).
Angles: $rr' = {}^*92° 20'$, $ce = 36° 58'$, $cg = 50° 18'$, $cs = 71° 37\frac{1}{2}'$, $ee' = 62° 46'$, $gg' = 83° 33\frac{1}{2}'$, $ss' = 110° 33'$.

Twins: tw. plane *e*, sometimes produced by pressure[3]. Natural crystals rare and usually indistinct; artificial crystals in parallel groups of cube-like rhombohedrons. Usually in reticulated and arborescent shapes; foliated and granular.

Cleavage: *c* perfect, *s* less so; *e* indistinct. Sectile. Brittle, but when heated somewhat malleable. H. = 2–2·5. G. = 9·70–9·83. Luster metallic. Streak and color silver-white, with a reddish hue; subject to tarnish. Opaque.

**Comp., Var.**—Pure bismuth, with occasional traces of arsenic, sulphur, tellurium.

**Pyr., etc.**—B.B. on charcoal fuses and entirely volatilizes, giving a coating orange yellow while hot, and lemon-yellow on cooling. Fuses at 265° C. Dissolves in nitric acid; subsequent dilution causes a white precipitate. Crystallizes readily from fusion.

**Obs.**—Bismuth occurs in veins in gneiss and other crystalline rocks and clay slate, accompanying various ores of silver, cobalt, lead and zinc. It is most abundant at the silver and cobalt mines of Saxony and Bohemia, as at Schneeberg, Altenberg, Joachimsthal, Johanngeorgenstadt, etc., with various bismuth minerals at Meymac, Corrèze, France. Also at Modum and Gjellebäk in Norway, at Falun and elsewhere in Sweden. At Schneeberg it forms arborescent delineations in brown jasper. At Wheal Sparnon, near Redruth, and elsewhere in Cornwall, and at Carrock Fells in Cumberland, it is associated with ores of cobalt; formerly from near Alva in Stirlingshire; in a large and rich vein at the Atlas mine, Devonshire; at San Antonio, near Copiapo, Chili; Mt. Illampa (Sorata) and Tazna, in Bolivia. In Victoria; the New England district, at Glen Inness, Kingsgate and elsewhere, New South Wales.

At Lane's mine in Monroe, Conn., it is associated in small quantities with wolframite, scheelite, galena, sphalerite, etc., in quartz, also at Booth's mine, Monroe; occurs also at Brewer's mine, Chesterfield district, South Carolina; near Cummins City, Colorado; also in the placers of French Creek, Summit Co., and the Las Animas mine, Boulder Co. (Randall).

**Ref.**—[1] Abh. Ak. Berlin, 90, 1849. [2] Fletcher, Phil. Mag., **9**, 185, 1880. [3] Mgg., Jb. Min., **1**, 183, 1886.

**12. ZINC.** Zink *Germ.* Zinco *Ital.*

Rhombohedral. Axis $\dot{c} = 1\cdot35643$; $0001 \wedge 10\bar{1}1 = {}^*57° 26\cdot6'$ Williams and Burton[1].

**Forms**[1]: $c$ $(0001, O)$, $q$ $(40\bar{4}7, \frac{4}{7})$, $s$ $(20\bar{2}3, \frac{2}{3})$, $r$ $(10\bar{1}1, R)$, $t$ $(30\bar{3}2, \frac{3}{2})$, $u$ $(60\bar{6}1, 6)$; also doubtful $v$ $(50\bar{5}2, \frac{5}{2})$, $w$ $(80\bar{8}3, \frac{8}{3})$, $x$ $(40\bar{4}1, 4)$, $y$ $(13\cdot0\cdot\bar{13}\cdot3, \frac{13}{3})$; also the corresponding negative forms $r_1$ $(01\bar{1}1, -1)$, etc. Angles: $cq = 41° 50'$, $cs = 46° 14'$, $ct = 66° 57'$, $cu = 83° 55\frac{1}{2}'$, $rr_1 = 49° 51'$, $rr' = 93° 46'$.

Obtained artificially in hexagonal prisms with tapering pyramids, strongly striated horizontally—these are either barrel-shaped or tabular; also in complex crystalline aggregates.
Zinc also appears to crystallize in the isometric system, at least in various alloys[2]

Cleavage: $c$ perfect; also rhombohedral (?). Rather brittle. Percussion-figure parallel to edges $cr$ and $cr_1$. H. = 2. G. = 6·9–7·2. Luster metallic. Color and streak white, slightly grayish. Zinc fuses at 420° C. and boils at about 1000° C.

**Obs.**—Native zinc has been reported from near Melbourne, Australia (see 5th Ed. p. 17); also from northeastern Alabama, Am. J. Sc., **11**, 234, 1876; also with sphalerite in Shasta Co., Cal. Its existence in nature, however, needs confirmation.

**Ref.**—[1] Am. Ch. J., **11**, 219, 1889. Cf. also Rose, Pogg., **83**, 129, 1851. [2] Nöggerath, ibid., **39**, 323, 1836. Cf. Rose, ib., **85**, 293, 1852, **107**, 448, 1859. J. P. Cooke, Am. J. Sc., **31**, 194, 1861.

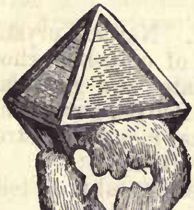
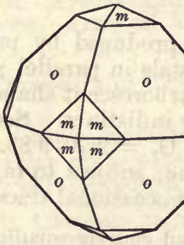
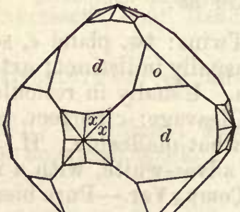
1.



2.

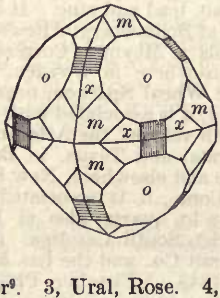


3.



4.

5.



6.

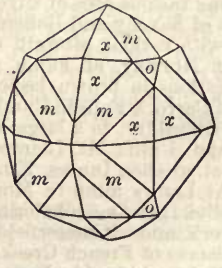


Fig. 1, California, Alger[9]. 3, Ural, Rose. 4, Ural, Helmhacker.
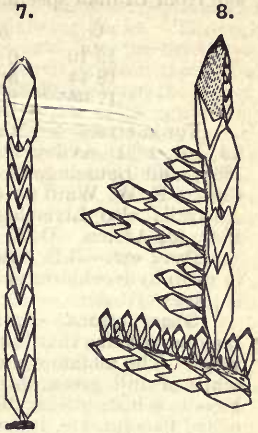
5, 6, California, E. S. D.[7]

Twins: tw. pl. *o*, often flattened ∥ *o*; also repeated and in complex groups[8]. Forms *d*, *o* common, also *m*. Crystals often elongated in direction of an octahedral axis, giving rise to rhombohedral forms (as *m* in f. 7, 8), and with parallel grouping to arborescent shapes; also in plates flattened ∥ *o*, and branching at 60° parallel either to the edges or diagonals of an *o* face. Skeleton crystals common; edges often salient, or again much rounded (f. 1, 4). Crystals irregularly distorted and passing into filiform, reticulated, dendritic shapes, and occasionally spongiform. Also massive and in thin laminæ; often in flattened grains or scales and rolled masses in sand or gravel.

Cleavage none. Fracture hackly. Very malleable and ductile. H. = 2·5–3. G. = 15·6–19·3, 19·33 when pure, Rose. Luster metallic. Color and streak gold-yellow, sometimes inclining to silver-white and rarely to orange-red. Opaque.

**Comp., Var.**—Gold, but usually alloyed with silver in varying amounts and sometimes containing also traces of copper or iron; rare varieties with palladium, rhodium and bismuth have been described.



7. 8.

White Bull Mine, Oregon, E. S. D.[7]

**Var.**—1. *Ordinary.* Containing up to 16 p. c. of silver. Color varying accordingly from deep gold-yellow to pale yellow, and specific gravity from 19·3 to 15·5. The ratio of gold to silver of 3 : 1 corresponds to 15·1 p. c. silver.

The purest gold which has been described is that from Mount Morgan, in Queensland, which has yielded 99·7 to 99·8 of gold, the remainder being copper with a little iron; silver is present only as a minute trace (Leibius, R. Soc. N. S. W., **18**, 37. 1884). Gold from Maryborough, Victoria, assayed 99·3 p. c. The purest Uralian specimen analyzed by Rose gave: Au 98·96, Ag 0·16. Cu 0·35. Fe 0·05 = 99·52, with G. = 19·10.

2. *Argentiferous; Electrum.* *Λευκός χρυσός Herod.; Ἤλεκτρον Homer, Strabo;* Electrum *Plin.*, **33**, 23. Oroche *Span.* Color pale yellow to yellowish-white; G. = 15·5–12·5. Ratio for the gold and silver of 1 : 1 corresponds to 36 p. c. of silver; 1½ : 1, to 26 p. c.; 2 : 1, to 21 p. c.; 2½ : 1. to 18 p. c. Pliny says that when the proportion of silver in the gold is one-fifth (= 20 p. c.) it is called *electrum.* The word in Greek means also *amber;* and its use for this alloy probably arose from the pale yellow color it has as compared with gold.

Electrum from Verespatak has afforded 38·7 p. c. Ag, from the Altai 38·4 p. c., from New Granada 17·6 to 35·1 p. c., from Peru 20 p. c. See 5th Ed. pp. 4, 5. The Bodie electrum has G. = 15·15, and contains Au 63·34, Ag 36·41 = 99·75. (Hanks, 4th Cal. Min. Rep., 191, 1884.) A specimen from Montgomery Co., Va., gave Porcher: Au 65·31, Ag [34·01], Cu 0·14, Fe 0·20, quartz 0·34 = 100; G. = 15·46, Ch. News, **44**, 189, 1881.

3. *Palladium-Gold.* *Porpezite* Fröbel. A variety from "Porpez," Brazil, containing 10 p. c. of palladium, besides some silver, color pale; also from Jacutinga and Condonga with 5 to 6 p. c. Pd. Porpez, however, is probably a corruption of Pompeõ, an old mining settlement near Sabara, in which vicinity palladium-gold occurs rather abundantly (Derby, priv. contr.). A specimen from Taguaril, Minas Geraes, gave Seamon: Au 91·06, Pd 8·21, Ch. News, **46**, 216, 1882

4. *Rhodium-Gold.* *Rhodite,* Adam, Tabl. Min., 83, 1869. Contains, according to del Rio (Ann Ch. Phys., **29**, 137, 1825), 34–43 p. c. of rhodium; G. = 15·5–16·8. Brittle. Requires reëxamination

5. *Bismuth-Gold.* Black gold *Austr. miners.* Maldonite *Ulrich,* Contrib. Min. Victoria, 1870. Corresponds to $Au_2Bi$ = Gold 65·5, bismuth 34·5 = 100. Newbery (l.c.) found Au 64·5, Bi 35·5; and McIvor Au 65·12, Bi 34·88 = 100, Ch. News. **55**, 191, 1887. Color pinkish silver-white, tarnishing on exposure. Luster metallic. Occurs in quartz from Nuggety Reef, Maldon, Victoria. Shepard's doubtful *bismuthaurite,* or bismuthic gold, may be similar.

California gold is mostly from 87 to 89 per cent fine, the average being 88 (U. S. Mint); many analyses, however, run up to 95 p. c. or higher, while others are classed with electrum. The gold from Chaudière, Canada, contains 10 to 15 p. c. silver. that of Nova Scotia is nearly pure. For the Australian gold (Miller, Liversidge), that from Victoria contains about 96 p. c. gold, 3·5 silver, and 0·5 of other metals. North of this in New South Wales the average fineness is 93·5 gold, 6 p. c. silver, the assays ranging mostly from 90 to 96. In Queensland the average is 87·25 p. c. gold and 12 p. c. silver, and for Maryborough 85 p. c. gold and 14 p. c. silver. Farther north the gold becomes richer again, that from the Palmer river washings containing but little silver; that of Mt. Morgan (as noted above) is nearly pure. The New Zealand gold of the Otago, or southern fields, is said to contain less than 6 p. c. silver with a little copper, that of Nelson 10 to 14 p. c. silver, and that of the Thames or northern fields over 30 p. c. silver (S. H. Cox, Trans. N. Z. Inst. **14**, 446, 1881).

Rose (l. c., p. 191) gives the following determinations of specific gravity and silver percentage from Uralian specimens.

| G. | Ag | G. | Ag | G. | Ag |
|---|---|---|---|---|---|
| 19·10 | 0·16 | 17·59 | 9·02 | 16·87 | 13·19 |

For analyses, see 5th Ed. pp. 4, 5, and authorities there mentioned, especially Rose, Pogg., **23**, 161, 1831; Avdeyev, ib., **53**, 153, 1841, for the Ural. Forbes, Phil. Mag., **29**, 129, **30**, 142, 1865; and Boussingault. Ann. Ch. Phys., **34**, 408, 1827, for So. America; also, Domeyko, Min. Chili. E. W. Ward (in Clarke's Researches in Southern Gold Fields, Sydney, 1860, p. 276) for Australia, also Liversidge, Min. N. S. W., 1888, pp. 14–17. Levol, Ann. Ch. Phys., **27**, 310, 1849, for Africa. O. C. Marsh, Am. J. Sc., **32**, 395, 1861, Nova Scotia.

**Pyr., etc.**—B.B. fuses easily. Not acted on by fluxes. Insoluble in any single acid; soluble in nitro-hydrochloric acid (aqua-regia), the separation is not complete if more than 20 p. c. Ag is present (Rose).

**Observations.**—Native gold is found, when *in situ*, with comparatively small exceptions, in the quartz veins that intersect metamorphic rocks, and to some extent in the wall rock of these veins. The metamorphic rocks thus intersected are mostly chloritic, talcose, and argillaceous schist of dull green, dark gray, and other colors; also, much less commonly, mica and hornblendic schist, gneiss, diorite, porphyry; and still more rarely, granite. A laminated quartzyte, called itacolumyte, is common in many gold regions, as those of Brazil and North Carolina, and sometimes specular schists, or slaty rocks containing much foliated specular iron (hematite), or magnetite in grains. A quartzose conglomerate is sometimes richly auriferous as in Transvaal. Less frequently calcite is the vein material, as at Minersville, Trinity Co., Cal. (Diller), and at many points in New South Wales (Liversidge). Gold has also been noted in scales embedded in serpentine.

The gold occurs in the quartz in strings, scales, plates, and in masses which are sometimes an agglomeration of crystals; and the scales are often invisible to the naked eye, massive quartz that apparently contains no gold frequently yielding a considerable percentage to the assayer. It is always very irregularly distributed, and never in continuous pure bands of metal, like many metallic ores. It occurs both disseminated through the mass of the quartz, and in its cavities, the larger masses and the finer crystallizations mainly in the latter.

The associated minerals are: pyrite, which far exceeds in quantity all others, and is generally *auriferous;* next, chalcopyrite, galena, sphalerite, arsenopyrite, each frequently auriferous; often tetradymite and other tellurium ores, native bismuth, native arsenic, stibnite, cinnabar, magnetite, hematite; sometimes barite, scheelite, apatite, fluorite, siderite, chrysocolla. The quartz at the surface, or in the upper part of a vein, is usually cellular and rusted from the more or less complete disappearance of the pyrite and other sulphides by decomposition; but below, it is commonly solid.

The gold of the world has been mostly gathered, not directly from the quartz veins (the "quartz reefs" of Australia), but from the gravel or sands of rivers or valleys in auriferous regions, or the slopes of mountains or hills, whose rocks contain in some part, and generally not far distant, auriferous veins; and such mines are often called *alluvial washings;* in California *placer-diggings*. Pliny speaks of the "bringing of rivers from the mountains, in many instances for a hundred miles, for the purpose of washing the débris," and this method of hydraulic mining has been carried on in California on a stupendous scale. (See Silliman, in Am. J. Sc., **40**, 10, 1865.) The auriferous gravel beds in California were of vast extent; those of the Yuba, an affluent of Feather River, varying from 80 to 250 feet in depth, and averaging probably 120 feet. Most of the gold of the Urals, Brazil, Australia, and all other gold regions, has come from such alluvial washings. At the present time, however, the alluvial washings are much less depended upon, in many regions all the gold being obtained direct from the quartz.

The alluvial gold is usually in flattened scales of different degrees of fineness, the size depending partly on the original condition in the quartz veins, and partly on the distance to which it has been transported. Transportation by running water is an assorting process; the coarser particles or largest pieces requiring rapid currents to transport them, and dropping first, and the finer (*float gold*) being carried far away—sometimes scores of miles. A cavity in the rocky slopes or bottom of a valley, or a place where the waters may have eddied, generally proves in such a region to be a *pocket* full of gold. The rolled masses when of some size are called *nuggets* (pepitas, *Span. S. A.*); in rare cases these occur very large and of great value. The Australian gold region has yielded many large nuggets; one of these found in 1858 weighed 184 pounds, and another (1869) weighed 190 pounds. In the auriferous sands, crystals of zircon are very common; also garnet and cyanite in grains; often also monazite, diamonds, topaz, corundum, iridosmine, platinum. The zircons are sometimes mistaken for diamonds.

Besides the free gold of the quartz veins and gravels, much gold is also obtained from auriferous sulphides or the oxides produced by their alteration, especially pyrite, also arsenopyrite, chalcopyrite, sphalerite, marcasite, etc. At Steamboat Springs, Nevada, gold is being deposited at the present time and probably from solution in alkaline sulphides, together with sulphides of arsenic, antimony, and mercury, and other compounds, chiefly sulphides. (Cf. Becker, U. S. Geol. Surv., Mon. **13**, 1888.)

Gold is widely distributed over the globe, and occurs in rocks of various ages, from the Archean to the Cretaceous or Tertiary. The schists that contain the auriferous veins were once sedimentary beds of clay, sand, or mud, derived from the wear of preëxisting rocks. Through some process, in which heat was concerned, the latter were metamorphosed into the hard crystalline schists, and at the same time upturned and broken, and often opened between the layers; and then all the fissures (cutting across the layers) and the openings (made between the layers, and therefore conforming with the lamination) became filled with the quartz veins containing gold. The quartz was brought into the intersecting fissures, and the interlaminated open spaces, from the rocks either side by means of the permeating heated waters (such heated waters, at a temperature much above that of boiling water, having great decomposing and solvent power, and carrying into cavities whatever they can gather up from the rocks). Thus, the gold of the veins was derived from the rocks adjoining the openings, either directly adjoining, or above, or below it; and it must therefore have been widely distributed through these rocks before they were crystallized and the veins were made, although in an infinitesimal quantity in a cubic foot. As schists with auriferous quartz veins were made in Archean time, so were they also in Paleozoic, especially at the great mountain-making epoch which closed the Paleozoic era; also later, in the Jurassic period, as in the Sierra Nevada; and still later in the Cretaceous and Tertiary periods, as in the Coast Ranges of California. But whatever the age of the schists and veins, the original source of all the Paleozoic and later gold deposits must be the original rocks of the globe, as they are the great source of the material of the shales and sandstones of subsequent ages, excepting such as may have been derived from aqueous solution or chemical deposition. Auriferous quartz veins are in no case *igneous* veins—that is, veins filled by injection of melted matter from below.

Gold exists more or less abundantly over all the continents in most of the regions of crystalline rocks, especially those of the semi-crystalline schists; and also in some of the large islands of the world where such rocks exist. In Europe, it occurs with silver ores in Hungary at Königsberg, Schemnitz, Kapnik, and Felsöbánya, and in Transylvania at Verespatak, often finely crystallized, and Nagyág chiefly with tellurium minerals; it occurs also in the sands of the Rhine, the Reuss, the Aar, the Rhone, and the Danube; on the southern slope of the Pennine Alps from the Simplon and Monte Rosa to the valley of Aosta; in Piedmont; in Spain, formerly worked in Asturias; in many of the streams of Cornwall; near Dolgelly and other parts of North Wales; in Scotland, in considerable amount, near Leadhills, and in Glen Coich and other parts of Perthshire; in the county of Wicklow, Ireland; in Sweden, at Edelfors; in Norway, at Kongsberg.

In Asia, gold occurs along the eastern flanks of the Urals for 500 miles, and is especially abundant at the Berezov mines near Ekaterinburg (lat. 56° 40′ N.); also obtained at Petropavlovski (60° N.); Nizhni Tagilsk (59° N.); Miask, near Zlatoust and Mt. Ilmen (55° N., where the largest Russian nugget was found), etc. Ekaterinburg is the capital of the mining district. The Urals were within the territory of the ancient Scythians; and the vessels of gold reputed, according to Herodotus, to have fallen from the skies, were probably made from Uralian nuggets. But the mines were not opened until 1819; soon after this they became the most productive in the world, and remained so until the discoveries in California. Siberian mines less extensive occur in the lesser Altai, in the Kolyvan mining region, about 1500 miles east of Ekaterinburg, near long. 100° E., between the Obi and Irtish, and 1500 miles west of the other great Siberian mining region, that of Nerchinsk, which is between 135° and 140° E., east of L. Baikal, including the Kara mines; among the localities are Zmeinogorsk and Ziryanovski, noted for affording the electrum. Asiatic mines occur also in the Cailas Mountains, in Little Thibet, Ceylon, and Malacca, China especially in the Amur district, Corea, Japan, Formosa, Sumatra, Java, Borneo, the Philippines, and other East India Islands; at numerous points in British India, especially Mysore.

In Africa, gold occurs at Kordofan, between Darfur and Abyssinia; also, south of the Sahara in western Africa, from the Senegal to Cape Palmas; in the interior, on the Somat, a day's journey from Cassen. Also in Transvaal in southern Africa, at Lydenburg, both quartz veins and alluvial washings, and at Eersteling; recently the Kaap gold fields in southeastern Transvaal have become very productive: the chief town of the region is Barberton. The quartz reefs of Witwatersrand in the immediate vicinity of Johannesburg, farther west, have also some very rich mines; here the gold occurs largely in a quartzose conglomerate.

In South America, gold is found in Brazil (where formerly the larger part of the annual produce of the world was obtained) along the chain of mountains nearly parallel with the coast, especially near Villa Rica, and in the province of Minas Geraes; in the U. S. of Colombia, at Antioquia, Choco, and Giron; Chili; in Bolivia, especially in the valley of the Rio de Tipuani, east of Sorata; sparingly in Peru. Also in Central America, in Honduras, San Salvador, Guatemala, Costa Rica, and near Panama; most abundant in Honduras, especially along the rivers Guyape and Jálan, in Olancho, while found also in the department of Yoro, and in southern Honduras.

In Australia, the principal gold mines occur along the streams in the mountains of N. S. Wales (S. E. Australia), and along the continuation of the same range in Victoria. It was discovered in N. S. Wales, near Bathurst, in the spring of 1851; and in August of the same year, the far richer deposits of Victoria became known; up to the present time these have yielded double the amount from the remainder of Australia with New Zealand and Tasmania included. Also obtained largely in Queensland, N. Australia, particularly at Mt. Morgan, Rockhampton district. Also occurs in Tasmania. In New Zealand there are three distinct gold fields, as already noted. Found also in New Caledonia.

In North America, there are numberless mines along the mountains of western America, and others along the eastern range of the Appalachians from Alabama and Georgia to Labrador, besides some in portions of the intermediate Archean region about Lake Superior. They occur at many points along the higher regions of the Rocky Mountains, in Mexico, in New Mexico, near Santa Fé, Cerillos, Avo, etc.; in Arizona, in the San Francisco, Wauba, Yuma, and other districts; in Colorado, abundant, the gold largely in auriferous pyrites, also in connection with tellurium minerals; also in Montana, the Black Hills of Dakota, Idaho especially the Cœur d'Alene district, also Utah. Along ranges between the summit and the Sierra Nevada, in the Humboldt region and elsewhere. Also in the Sierra Nevada, mostly on its western slope (the mines of the eastern being principally silver mines). The auriferous belt may be said to begin in the Californian peninsula. Near the Tejon pass it enters California, and beyond for 180 miles it is sparingly auriferous, the slate rocks being of small breadth; but beyond this, northward, the slates increase in extent, and the mines in number and productiveness, and they continue thus for 200 miles or more. Gold occurs also in the Coast ranges in many localities, but mostly in too small quantities to be profitably worked. The regions to the north in Oregon and in Washington and Alaska, with British Columbia, are at many points auriferous, and productively so, though to a less extent than California. The Cariboo region on the Fraser river, and the Cassiar district on the Stickeen have yielded considerable amounts. The Alaska quartz mines have been worked to some advantage, as also the gravels of the Yukon river.

The mines of California were first made known in 1849. They were for some years solely alluvial washings, but in 1852 quartz mining became prominent, and of late years placer mining has largely ceased. The quartz veins are often of great size. Some in the "Mariposa estate" average 12 feet, and in places expand to 40 feet in breadth. North of Mariposa county, the auriferous gravel, which has everywhere been a principal source of the gold thus far obtained, is very extensive. The thick deposits, often semi-indurated, have been washed down by vast streams of water thrown by the pressure of a column of water of 150 feet, that do the work of running off the earth and gravel, and gathering the gold in an incredibly short time. Much of the auriferous gravel formation is under a covering of volcanic rock, either tufa or lavas, which has to be underworked, in one way or another, to get out the gold, making what is called *table-mountain mining;* the flat tops of hard volcanic material giving a table-like look to the heights. See J. D. Whitney's Geol. California (review in Am. J. Sc., **41**, 231, 351, 1866), and, by the same author, The Auriferous Gravels of the Sierra Nevada of California, Cambridge, 1880 (Mem. Mus. Comp. Zoöl., **6**, No. 1). Also Precious Metal Deposits of the Western United States, by S. F. Emmons and G. F. Becker, 1885; and Min. Res. U. S., 1882–1888.

In eastern North America, the mines of the Southern United States produced before the California discoveries about a million of dollars a year. They are mostly confined to the States of Virginia, North and South Carolina, and Georgia, or along a line from the Rappahannock to the Coosa in Alabama. But the region may be said to extend north to Canada; for gold has been found at Albion and Madrid in Maine; Canaan and Lisbon, N. H.; Bridgewater, Vermont; Dedham, Mass. Traces occur also in Franconia township, Montgomery Co., Pennsylvania. In Virginia, the principal deposits are in Spottsylvania county, on the Rappahannock, at the United States mines, and at other places to the southwest; in Stafford county, at the Rappahannock gold mines, ten miles from Falmouth; in Culpepper county, at the Culpepper mines, on Rapidan river; in Orange county, at the Orange Grove gold mine, and at the Greenwood gold mines; in Goochland county, at Moss and Busby's mines; in Louisa county, at Walton's gold mine; in Buckingham county, at Eldridge's mine. In North Carolina, the gold region is mostly confined to the counties of Montgomery, Cabarrus, Mecklenburg, and Lincoln. The mines of Mecklenburg are principally vein deposits; those of Burke, Lincoln, McDowell, and Rutherford, are mostly in alluvial soil; the Davidson county silver mine has afforded gold. In Georgia, the Shelton gold mines in Habersham county have long been famous; and many other places have been opened in Rabun and Hall counties, Lumpkin county, at Dahlonega, etc.; and the Cherokee country. In South Carolina, the principal gold regions are the Fairforest in Union district, and the Lynch's creek and Catawba regions, chiefly in Lancaster and Chesterfield districts; also in Pickens county, adjoining Georgia. There is gold also in eastern Tennessee.

In Canada, gold occurs to the south of the St. Lawrence, in the soil on the Chaudière (where first found in 1835), and over a considerable region beyond, having been derived probably from the crystalline schists of the Notre Dame range (T. S. Hunt). In Nova Scotia, mines are worked near Halifax and elsewhere. Arsenopyrite is worked for gold at Deloro near Hastings, Ontario. Gold also occurs in the Port Arthur region, north of Lake Superior, and in the river-gravels of the Pacific slope, as before noted.

The world's yield of gold has very much increased in amount since the discovery of the mines of California. The mines of South America and Mexico were estimated by Humboldt, in the early part of the century, to yield annually $11,500,000, which considerably exceeds the present proceeds. It is estimated that, between 1790 and 1830, Mexico produced $31,250,000 in gold, Chili $13,450,000, and Buenos Ayres $19,500,000, making an average annual yield of $16,050,000. The Russian mines in 1846 produced about $16,500,000; and in 1851, $15,000,000, while for 1887 the amount is $20,000,000. The yield of California in 1849, the first year after the discovery of the gold, was $5,000,000. It rapidly increased from that year until 1853, when it was nearly $60,000,000. Since then it has diminished, and in 1866 the amount was but $27,000,000;

and from 1881 to 1888 it has varied from \$18,200,000 to \$12,750,000. Montana, Colorado, Nevada, Dakota, Idaho, etc., raise the total from the United States for the year 1888 to over \$33,000,000, with \$59,206,700 for silver in addition. The silver production in the U. S. for 1890 was \$70,485,714 (Leech). Australia produced \$60,000,000 for a numbers of years; but for 1863, 1864, 1865, the average was not above \$30,000,000, and from 1884 to 1887 the yield (including New Zealand and Tasmania) has varied from \$28,284,000 to \$26,425,000.

The following tables are taken from the report for 1891 of the ~~Director of~~ the U. S. Mint, Edward O. Leech; figures for recent years above from the reports of James P. Kimball.

World's Production of Gold for 1890.

| | | | |
|---|---|---|---|
| United States | \$32,845,000 | Austria-Hungary | \$1,398,500 |
| Australasia | 30,416,500 | Germany | 1,230,000 |
| Russia | 21,161,700 | Venezuela | 1,158,000 |
| Africa | 9,887,000 | Mexico | 767,000 |
| China | 5,330,000 | Brazil | 445,300 |
| Colombia | 3,695,000 | Japan | 254,000 |
| British India | 2,000,000 | Italy | 98,000 |
| Dominion of Canada | 1,495,000 | Peru | 69,000 |
| Chili | 1,436,600 | Other Countries* | 2,322,300 |
| | | Total | \$116,008,900 |

United States Production of Gold for 1890.

| | | | |
|---|---|---|---|
| California | \$12,500,000 | Alaska | \$762,500 |
| Colorado | 4,150,000 | Utah | 680,000 |
| Montana | 3,300,000 | Washington | 204,000 |
| Dakota, South | 3,200,000 | N. Carolina | 118,500 |
| Nevada | 2,800,000 | Georgia | 100,000 |
| Idaho | 1,850,000 | S. Carolina | 100,000 |
| Oregon | 1,100,000 | Michigan | 90,000 |
| Arizona | 1,000,000 | Other States† | 40,000 |
| New Mexico | 850,000 | | |
| | | Total | \$32,845,000 |

**Ref.**—[1] See Helmhacker for early authorities and description of crystals from Sysertsk, Min. Mitth., 1, 1877. Note also Rose, Pogg., **23**, 196, 1831, Reis. Ural, **1**, 198 et al., 1837, and Rath, Zs. Kr., **1**, 1, 1877. Dx. mentions also *z* (543).

† Alabama, Maryland, Tennessee, Virginia, Vermont, Wyoming.

**Comp., Var.**—Silver, with some gold, copper, and sometimes platinum, antimony, bismuth, mercury (Kongsberg, 0·4 p. c. Forbes).

Var. 1. *Ordinary.* (*a*) crystallized; (*b*) filiform, arborescent; (*c*) massive.

2. *Auriferous; Küstelite.* Güldisch-Silber *Hausm.*, Handb. 104, 1813. Küstelit *Breith.*, B. H. Ztg., **25**, 169, 1866. Contains 10 to 30 p. c. of gold; color white to pale brass-yellow. There is a gradual passage to argentiferous gold (see GOLD).

The name *Küstelite* was given to an ore from Nevada, having the following characters: H. = 2–2·5; G. = 11·32–13·10; color silver-white, somewhat darker than native silver on a fresh surface; Richter found in it silver, lead, and gold, the first much predominating. From the Ophir mine, Nevada, in bean-shaped grains. Named after Guido Küstel.

3. *Cupriferous.* Contains sometimes 10 p. c. of copper.

**Pyr., etc.**—B.B. on charcoal fuses easily to a silver-white globule, which in O.F. gives a faint dark red coating of silver oxide; crystallizes on cooling; fusibility about 1050° C. Soluble in nitric acid, and deposited again by a plate of copper. Precipitated from its solutions by hydrochloric acid in white curdy forms of silver chloride.

**Obs.**—Native silver occurs in masses, or in arborescent and filiform shapes, in veins traversing gneiss, schist, porphyry, and other rocks. Also occurs disseminated, but usually invisibly, in native copper, galena, chalcocite, etc.; rarely in volcanic ashes (Mallet).

The mines of Kongsberg, in Norway, have afforded magnificent specimens of native silver, sometimes in very large masses. One in the collection at Copenhagen weighs upward of 5 cwt. The principal Saxon localities are at Freiberg, Schneeberg, and Johanngeorgenstadt; the Bohemian, at Přibram and Joachimsthal. It also occurs in small quantities with other ores, at Andreasberg in the Harz; in Suabia; Hungary; at Allemont in Dauphiné; in the Ural near Berezov; in the Altai, at Zmeov; and in some of the Cornish mines.

Mexico and Peru have been the most productive countries in silver. In Mexico, it has been obtained mostly from its ores, while in Peru it occurs principally native. A Mexican specimen from Batopilas weighed when obtained 400 pounds; and one from southern Peru (mines of Huantaya) weighed over 8 cwt. During the first eighteen years of the present century, more than 8,180,000 marks of silver were afforded by the mines of Guanajuato alone. In Durango, Sinaloa, and Sonora, in northern Mexico, are noted mines affording native silver.

In the United States it is disseminated through much of the copper of Michigan, occasionally in spots of some size, and sometimes in cubes, skeleton octahedrons, etc., at various mines; at Silver Islet and at Port Arthur on the north side of L. Superior. It has been observed at a mine a mile south of Sing Sing prison, which was formerly worked for silver; at the Bridgewater copper mines, New Jersey; at King's mine, Davidson Co., N. C.; rarely in filaments with barite at Cheshire, Ct. In Idaho, at the "Poor Man's lode," large masses of native silver have been obtained. In Nevada, in the Comstock lode, it is rare, and mostly in filaments; at the Ophir mine rare, and disseminated or filamentous; in California, sparingly, in Silver Mountain district, Alpine Co.; in the Maris vein, in Los Angeles Co.

In Colorado, at many localities, common at the Caribou mine, Boulder Co.; Georgetown, Clear Creek Co., with argentiferous ores; rather rare at the Leadville mines, less so in the Ruby district, Gunnison Co. In Montana, near Butte, Silver Bow Co., with manganese ores, also with pyrite and chalcopyrite. In Idaho, at the Jessie Benton mine, Atlanta. In Arizona, common at the Silver King mine, and with argentiferous ores elsewhere.

**Alt.**—Pseudomorphs, consisting of cerargyrite, red silver ore, argentite and stephanite.

Twins: tw. pl. *o*, very common (f. 7); often flattened in direction of twinning axis, also elongated ‖ diagonal of twinning plane to acute spear-shaped forms (figs. 9, 10, 11), sometimes to thin plates. Forms with rhombohedral symmetry about the octahedral axis common especially with twins (f. 8). Often in complex groups branching at 60° in the direction of (1) the edges, and (2) the diagonals of the octahedral face, which is usually the twinning plane, the lower side then in twinning position to the upper, cf. figs. 12, 13, the former ideal; also grouped after more complex methods; sometimes in fivelings[5]. In parallel groupings of simple forms extended in the direction of the cubic axes (f. 14).

The tetrahexahedrons *e, h, k, l*, the most common forms both in twins and simple crystals. Crystals often with cavernous faces; also with elevations, especially octahedral plates hexagonal (*e*) or scalenohedral (*h*, etc.) in form. Crystals often irregularly distorted and passing into twisted bands of indistinct form and thus into wire-like forms. Often filiform and arborescent. Massive; as sand.

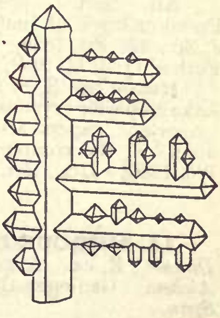
14.



Copper crystals from Lake Superior[1].

Cleavage none. Fracture hackly. Highly ductile and malleable. H. = 2·5–3. G. = 8·8–8·9, 8·838 Whitney. Luster metallic. Color copper-red. Streak metallic shining. Opaque. An excellent conductor for heat and electricity.

**Comp.**—Pure copper; often containing some silver, bismuth, mercury, etc.

**Pyr., etc.**—B.B. fuses readily; on cooling becomes covered with a coating of black oxide. Dissolves readily in nitric acid, giving off red nitrous fumes, and produces a deep azure-blue solution with ammonia. Fusibility 780° C.

**Obs.**—Copper occurs in beds and veins accompanying its various ores, especially cuprite, malachite and azurite; also with sulphides, chalcopyrite, chalcocite, etc. It is often abundant in the vicinity of dikes of igneous rocks; also in clay slate and sandstone.

In Siberia, and on Nalsoe, one of the Färöer, it is associated with mesotype, in amygdaloid, and though mostly disseminated in minute particles, sometimes branches through the rock with extreme beauty. At Turinsk, in the Ural, in fine crystals; also at Nizhni Tagilsk, the Bogoslovsk mines, and elsewhere. In Germany, at the Friedrichssegen mine, near Oberlahnstein, Nassau; at Rheinbreitbach on the Rhine. Common in Cornwall at many of the mines near Redruth; and also in considerable quantities at the Consolidated mines, Wheal Buller, and others; one mass from Mullion weighed three tons. In serpentine in the Lizard district. Brazil, Chili, Bolivia, and Peru afford native copper; a mass now in the museum at Lisbon, supposed to be from a valley near Bahia, weighs 2616 pounds; north of Tres Puntos, desert of Atacama, a large vein was discovered in 1859. In Bolivia, at Corocoro, in sandstone, and called in commerce "*Barilla de Cobre*" (copper barilla). Also found at some localities in China and Japan. In South Australia it occurs abundantly at Wallaroo on Yorke Peninsula and other mines near Adelaide; at Bathurst and elsewhere in New South Wales.

Occurs native throughout the red sandstone (Jura-Trias) region of the eastern United States, in Massachusetts, Connecticut, and more abundantly in New Jersey, where it has been met with sometimes in fine crystalline masses, especially at New Brunswick, Somerville, Schuyler's mines, and Flemington. Near N. Brunswick a vein or sheet of copper, a line or so thick, has been traced for several rods. Near New Haven, Conn., a mass was found in the drift weighing nearly 200 pounds; another of 90 pounds and several smaller isolated masses have also been dug up at different times.

The Lake Superior copper region, near Keweenaw Point, in northern Michigan, is the most important locality in the world. The copper is obtained practically all in the native state, and is obtained over an area 200 miles in length. The yield of native copper in 1887 from this region was about 37,000 tons, the Calumet and Hecla mine yielding much more than half. Masses of great size were observed in this district near the Ontanagon river, by Mr. Schoolcraft, in 1821. (Am. J. Sc., **3**, 201, 1821.) The largest single mass yet found was discovered in February, 1857, in the Minnesota mine, in the belt of conglomerate which forms the foot-wall of the vein. It was 45 feet in length, 22 feet at the greatest width, and the thickest part was more than 8 feet. It contained over 90 p. c. copper, and weighed about 420 tons. This copper contains silver, sometimes in visible grains, lumps, or strings, and occasionally a mass of copper, when polished, appears sprinkled with large silver spots, resembling, as Dr. Jackson observes, a porphyry with its feldspar crystals. The copper occurs in both amygdaloidal doleryte and sandstone, near the junction of these two rocks. It is associated with prehnite, datolite, analcite, laumontite, pectolite, epidote, chlorite, wollastonite, and sometimes coats amygdules of calcite, etc., in amygdaloid. Strings of copper often reticulate through crystals of analcite and prehnite. Pseudomorphs after scalenohedrons of calcite are sometimes met with. Besides this occurrence in the vicinity of trap, it is also in some parts of the Keweenaw region distributed widely in grains through the sandstone, especially in a conglomerate of quartz and jasper pebbles.

Native copper occurs sparingly in California; at the Union and Keystone, Napoleon and Lancha Plana mines in Calaveras Co.; in the Cosumnes mine, Amador Co.; in serpentine, in Sta. Barbara Co. Also in Arizona, common at the Copper Queen mine, Cochise Co. In Grant Co., N. Mexico, at the Santa Rita and other mines.

**Alt.**—Native copper is readily altered on exposure to cuprite, malachite, sometimes to azurite. Pseudomorphs of native copper *after* azurite occur in Grant Co., New Mexico (Yeates, Am. J. Sc., **38**, 405, 1889); also replacement pseudomorphs after aragonite at Corocoro, Bolivia, see Forbes, Q. J. G. Soc., **17**, 45, 1861; Domeyko, 6th App. Min. Chili, 6, 1878.

**Ref.**—[1] See E. S. D., Am. J. Sc., **32**, 413, 1886, or Zs. Kr., **12**, 569, 1887, for description of Lake Superior crystals, twinning, methods of grouping, etc.; also for authorities, literature, etc. Important papers are the following: [2] Rose, Reis. Ural, **1**, 313, 401; **2**, 453, 1837, who first described the complex groups; also [3] Rath, Zs. Kr., **2**, 169, 1878; [4] Fletcher, Phil. Mag., **9** 180, 1880; [5] Lsx., Ber. nied. Ges., **39**, 95, 1882.

**16. MERCURY.** *Χυτός ἄργυρος Theophr.* *Ὑδράργυρος καθ' ἑαυτὴν* [native] *Dioscor.*, E, cx. Argentum vivum, Hydrargyros, *Plin.* **33**, 32, 20, 41. Quicksilver. Mercurius *Alchem.* Gediegen Quecksilber *Germ.* Qvicksilfver *Swed.* Mercure natif *Fr.* Mercurio *Ital., Span.*

Liquid. Occurs in small fluid globules scattered through its gangue.

G. = 13·596 Regnault. Luster metallic, very brilliant. Color tin-white. Opaque.

**Comp.**—Pure mercury (Hg); with sometimes a little silver.

**Pyr., etc.**—B.B. entirely volatile, vaporizing at 350° C. Becomes solid at − 40° C., crystallizing in regular octahedrons with cubic cleavage; G. = 14·4. Dissolves readily in nitric acid.

**Obs.**—Mercury in the metallic state is a rare mineral; the quicksilver of commerce is obtained mostly from cinnabar. The rocks affording the metal and its ores are chiefly clay shales or schists of different geological ages. Also found in connection with hot springs in New Zealand, Iceland (?), and in California and Nevada.

At Cividale, in Venetian Lombardy, it is found in a marl regarded as a part of the Eocene nummulitic beds. Mercury has been observed occasionally in *drift;* and near Eszbetek, in Transylvania, and also Neumarkt, in Galicia, springs, issuing from the Carpathian sandstone, sometimes bear along globules of mercury. Its most important mines are those of Idria, in Carniola, and Almaden in Spain. At Idria it occurs interspersed through a clay slate, from which it is obtained by washing. It is found in small quantities at Wolfstein and Mörsfeld, in the Palatinate; in Carinthia, Hungary, Peru, and other countries; also at Peyrat le Chateau, in the department of the Haute Vienne, in a disintegrated granite, unaccompanied by cinnabar, also similarly near Montpellier in southern France; in California, at various cinnabar mines, especially at the Pioneer mine, in the Napa Valley. where quartz geodes have been found containing several pounds of mercury. Occurs with gold near Johannesburg, Transvaal, S. Africa; at Pakaraka, Bay of Islands, New Zealand.

On the distribution of mercury and cinnabar with a detailed account of the various localities, see Becker, U. S. G. Surv., Mon. **13**, 1888.

**17. AMALGAM.** Quicksilfwer amalgameradt med gediget Silfwer (fr. Sala) *Cronst.*, 189, 1758. Natürlich Amalgam, Silberamalgam, *Germ.* Amalgam natif *de Lisle*, **1**, 420, 1783. Mercure argental *H.* Pella natural *Del Rio.* Amalgama *Ital.*, *Span.* Plata mercurial *Span.*

Arquerite *Berth.*, *de B.*, *& Duf.*, C. R., **14**, 567, 1842, in Rep. on Art. by *Domeyko*, Ann. Mines, **20**, 268, 1841. Bordosite *Domeyko*, Min. Chili, 3d Ed., p. 362. Kongsbergite *Pisani*, C. R., **75**, 1274, 1872.

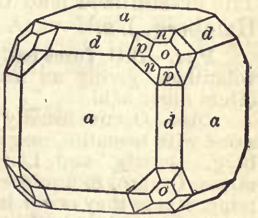
Isometric. Observed forms[1]:

*a* (100, *i-i*) *d* (110, *i*) *o* (111, 1) *f* (310, *i*-3) *e* (210, *i*-2) *p* (221, 2) *n* (211, 2-2) *s* (321, 3-$\frac{3}{2}$)

Crystals often highly modified; common habit dodecahedral. Also massive in plates, coatings, and embedded grains.

Cleavage: *d* in traces. Fracture conchoidal, uneven. Rather brittle to malleable. H. = 3–3·5. G. = 13·75–14·1. Luster metallic, brilliant. Color and streak silver-white. Opaque.

1.



Moschellandsberg
Lévy–Schrauf.

**Comp.**—(Ag,Hg), silver and mercury, varying from $Ag_2Hg_3$ to $Ag_{36}Hg$.

Percentage composition for $Ag_2Hg_3$ = silver 26·4, mercury 73·6 = 100; AgHg = silver 35·0, mercury 65·0 = 100. Also $Ag_5Hg_3$ = silver 52·7; $Ag_3Hg$ = silver 61·8; $Ag_4Hg$ = silver 68·3; $Ag_6Hg$ = silver 76·4; $Ag_{12}Hg$ = silver 86·6; $Ag_{36}Hg$ = silver 95·1.

**Var.**—1. *Ordinary amalgam*, $Ag_2Hg_3$ or AgHg. In crystals often highly modified, rather brittle. No recent analyses have been published. Also $Ag_5Hg_3$ (anal. 5), etc.

2. *Arquerite*, $Ag_{12}Hg$. G. = 10·8. Malleable and soft. Anal. 11–13.

3. *Kongsbergite*, $Ag_{32}Hg$ or $Ag_{36}Hg$. In crystals. Anal. 16, 17; anal. 18 gives $Ag_{39}Hg$.

Darapsky (l. c.) found the amount of mercury to vary somewhat widely even in different samples from the same specimen.

**Pyr., etc.**—B.B. on charcoal the mercury volatilizes and a globule of silver is left. In the closed tube the mercury sublimes and condenses on the cold part of the tube in minute globules. Dissolves in nitric acid. Rubbed on copper it gives a silvery luster.

**Obs.**—From the Palatinate at Moschellandsberg, in fine crystals, and said to occur where the veins of mercury and silver intersect one another; at Friedrichssegen near Oberlahnstein, Nassau. Also from Rosenau in Hungary, Sala in Sweden, Kongsberg in Norway, Allemont in Dauphiné, Almaden in Spain. In S. America, from the mines of Arqueros, Coquimbo, Chili (*arquerite* pt.); Rodaito near Arqueros; Rosilla, prov. Atacama; Bordos (*bordosite*). From Vitalle Creek, Br. Columbia (*arquerite*).

**Artif.**—Various artificial amalgams are known, cf. Rg., Kr. Ch., 170, 1881.

**Ref.**—[1] See Schrauf, Atlas, Tf. vi, vii, 1864; also Gdt., Index, **1**, 181, 1886.

**18. LEAD.** Plumbum nigrum *Plin.*, 34, 47. Saturnus *Alchem.* Gediegen Blei *Germ.* Gediget Bly *Swed.* Plomb natif *Fr.* Piombo nativo *Ital.* Plomo metálico *Span.*

Isometric. Observed forms[1]:

*a* (100, *i-i*) *d* (110, *i*) *o* (111, 1) *h* (410, *i*-4) *π* (551, 5) *n* (211, 2-2)

Twins: tw. pl. *o*. Crystals rare, octahedral or dodecahedral; usually in thin plates and small globular masses, also in dendritic, wire-like forms.

Very malleable, and somewhat ductile. H. = 1·5. G. = 11·37. Luster metallic. Color lead-gray. Opaque.

**Comp.**—Nearly pure lead; sometimes contains a little silver, also antimony. The crystallized lead from the Harstig mine gave 99·71 p. c. Pb, with G. = 11·372, Hamberg, l. c.

**Pyr.**—B.B. fuses easily, coating the charcoal with a yellow oxide which, treated in R. F., volatilizes, giving an azure-blue tinge to the flame. Fusibility 330° C. Dissolves easily in dilute nitric acid.

**Obs.**—Occurs usually in thin plates and embedded scales; thus in a compact dolomitic limestone with hematite, magnetite, and hausmannite, etc., at the iron and manganese mines of Pajsberg, Harstig, and Långban in Wermland, Sweden; similarly at Nordmark; at the Sjö mines, Örebro, in a mineral resembling neotocite. Crystals are known only from the Harstig mine, where they occur in cavities associated with the manganese silicate, caryopilite, and the arsenates, sarkinite and brandtite. Hamberg regards the native lead to have been reduced by the oxidation of arsenious acid. Found also in the gold washings of the Urals at Ekaterinburg and in the Altai, also on the Kirghese Steppes.

Also reported (but some of these are doubtful) as occurring in globules in galena at Alstonmoor; in lava in Madeira; at the mines near Carthagena in Spain; in Carboniferous limestone near Bristol, and at Kenmare, Ireland; according to R. P. Greg, Jr., in thin sheets in red oxide of lead near a basaltic dike in Ireland; in an amygdaloid near Weissig; in basaltic tufa, at Rautenberg, in Moravia; in the district of Zomelahuacan, in the State of Vera Cruz, in a granular limestone, containing in some places species of ammonites, in laminæ, in a foliated argentiferous galena; at Huancavelica, Peru.

In the U. S., reported from near Saratoga, N. Y., in crystalline limestone (but doubtful). At Breckinridge and Gunnison, Colorado. Jay Gould mine, Wood River district, Idaho. In the gold placers of Camp Creek, Montana.

**Artif.**—Metallic lead has long been known to crystallize in the isometric system; Lehmann has obtained electrolytically, besides this form, another in plates for which he suggests the monoclinic system[2].

**Ref.**—[1] Öfv. Ak. Stockh., **45**, 483, 1888, Zs. Kr., **17**, 253, 1889. [2] Zs. Kr., **15**, 274, 1889.

---

**19. TIN.** Plumbum candidum *Plin.*, 34, 47 Jupiter *Alchem.* Gediegen Zinn *Germ.* Gediget Tenn *Swed.* Etain natif *Fr.* Stagno nativo *Ital.* Estaño nativo *Span.*

In irregular rounded crystalline grains, or aggregations of grains, from 0·1 to 1 mm. in size; color grayish white. Occurs with platinum, iridosmine, gold, copper, cassiterite, corundum in washings from the Aberfoil and Sam rivers (headwaters of the Clarence river) near Oban, New South Wales. Howell, Genth, Am. Phil. Soc., 23, 30, 1885.

Native tin has also been reported as occurring with the Siberian gold; in the Rio Tipuani valley, Bolivia (probably artificial, Forbes); in Guanajuato, Mexico, under bismutite (Frenzel). All these are doubtful.

Artificial crystals are: (α) tetragonal, and (β) orthorhombic.

(α) Tetragonal. Axis ć = 0·3857, Mlr.[1] In prismatic crystals with *a* (100, *i-i*), *m* (110, *I*), *e* (101, 1-*i*), *t* (301, 3-*i*), *p* (111, 1), *r* (331, 3). Angles *pp'* = 39° 35', *pp''* = 57° 13', *ee'* = 29° 29', *ee''* = 42° 1[illegible]'. Also twins: tw. pl. (1) *p* (111), and (2) *r* (331).

H. = 2. G. = 7·178, after fusion 7·293 Mlr. Somewhat malleable. Luster metallic. Color tin-white. Obtained by the electrolytic decomposition of tin protochloride. Also from fusion in oscillatory pyramidal forms.

(β) Orthorhombic. Axes ă : b̄ : ć = 0·3874 : 1 : 0·3557, 100 ∧ 110 = 21° 10½', 001 ∧ 101 = 42° 33½', 001 ∧ 011 = 19° 34⅚', Trechmann[2]. In thin plates of prismatic crystals with *a* (100, *i*-ī), *b* (010, *i*-ĭ), *m* (110, *I*), *γ* (340, *i*-$\frac{4}{3}$)[3], *e* (120, *i*-2̆), *k* (101, 1-ī), *n* (021, 2-ĭ), *d* (111, 1), *p* (121, 2-2̆)[3]. Angles: *mm'* = 42° 21', *bm* = *68° 49½', *bn* = 54° 34', *dd'* = 81° 43', *dd'''* = 29° 22', *bd* = *75° 19'. The form approximates to that of the tetragonal variety, e.g., in the ratio of ă : ć.

Cleavage: *b*, *k* very imperfect. Brittle to mild. H. = above 2. G. = 6·54. Luster metallic. Color dark gray to bluish gray. Streak iron-gray, shining. Chemically nearly pure tin. Obtained from cavities of an arsenical slag produced in the process of tin-making, Cornwall.

**Ref.**—[1] Min., p. 127; Phil. Mag., **22**, 263, 1843. [2] Min. Mag., **3**, 186, 1879. [3] Foullon, Vh. G. Reichs., 237, 1881; see also Jb. G. Reichs., 367, 1884; he describes both the dimorphous forms.

---

## 5. Platinum-Iron Group.

**20. PLATINUM.** Platina (fr. Choco) *Ulloa*, Relac. Hist. Viage Amer. Merid., lib. 6, c. 10, Madrid 1748. Platina (fr. Carthagena) *W. Brownrigg* (who received it in 1741 from C. Wood), Phil. Trans., 584, 1750. Platina del Pinto *Scheffer*, Ak. H. Stockh., 269, 1752. Polyxen *Hausm.*, Handb., 97, 1813, 20, 1847.

Gediegen Platin *Germ.* Platine natif *Fr.* Platino *Ital.* Platina *Span.*

Isometric. Observed forms[1]:

*a* (100, *i-i*) *d* (110, *i*) *o* (111, 1) *f* (310, *i*-3) *e* (210, *i*-2) *l* (530, *i*-$\frac{5}{3}$) *g* (320, *i*-$\frac{3}{2}$)

Twins: tw. plane *o*. Crystals rare, cubes most common; often distorted. Usually in grains and scales, occasionally in irregular lumps or nuggets up to 20 pounds in weight.

Cleavage none. Fracture hackly. Malleable and ductile. H. = 4–4·5. G. = 14–19 native; 21–22 chem. pure. Luster metallic. Color and streak whitish steel-gray; shining. Sometimes magnetipolar.

**Comp.**—Platinum alloyed with iron, iridium, osmium and other metals.

**Var.**—1. *Ordinary.* *Non-magnetic* or only slightly magnetic. G. = 16·5–18·0 mostly. After washing in acid a distinction can be made between silver-white, gray, and iron-black grains.

2. *Magnetic.* G. about 14. Here is included Breithaupt's *Iron-platinum* (Eisenplatin), described as $PtFe_2$ with H. = 6 and G. = 14·6–15·8. Much platinum is magnetic, and occasionally it has polarity, so that platinum magnets are spoken of, comparable in power to the lodestone. The magnetic property seems to be connected with high percentage of iron, although this distinction does not hold without exception. Cf. Daubrée, C. R., **80**, 526, 1875.

A *nickeliferous* magnetic platinum from Nizhni Tagilsk gave Terreil: 8·18 Fe and 0·75 Ni, C. R., **82**, 1116, 1876.

**Anal.**—1–14, Minchin, Min. Russl., **5**, 184–190, 1866: anal. 3–7 of black grains washed with acid and then distinguished by color as given; anal. 8–12, ditto white grains. 15–17, Berzelius, Ak. [a] Including gangue.

**Pyr., etc.**—B.B. infusible. Not affected by borax or salt of phosphorus, except in the state of fine dust, when reactions for iron and copper may be obtained. Soluble only in heated nitrohydrochloric acid.

**Obs.**—Platinum was first found in pebbles and small grains, associated with iridium, osmium, palladium, gold, copper, and chromite, in the alluvial deposits of the river Pinto, in the district of Choco, near Popayan, in the U. S. of Colombia, South America, where it received its name *platina* (platina del Pinto) from *plata*, silver. In the province of Antioquia, in Brazil, it has been found in auriferous regions in syenite (Boussingault, Ann. Ch. Phys., **32**, 204, 1826).

In Russia, where it was first discovered in 1822, it occurs in alluvial material in the Urals at Nizhni Tagilsk, sometimes in nuggets of considerable size; also at Kushvinsk in the Goroblagodatsk district and at other points; in Nizhni Tagilsk it has been found with chromite in a serpentine probably derived from a peridotyte. In the sand of the Ivalo river, northern Lapland, associated with diamond and probably derived from a serpentine (altered peridotyte) containing chromite and diallage.

Platinum is also found on Borneo; in the sands of the Rhine; at St. Aray, Val du Drac; county of Wicklow, Ireland; on the river Jocky, St. Domingo; according to report, in Choloteca and Gracias, in Honduras. Also from the river Tayaka, in New Zealand, from a region characterized by a chrysolite rock (dunyte) with serpentine; similarly with nickeliferous metallic iron (awaruite) in the drift of the Gorge river; also from quartz lodes in the Thames gold fields (J. A. Pond). In New South Wales, reported as occurring *in situ* in the Broken Hill district, in a feldspathic rock with iridosmine; found in gold washings in small quantities at various points.

In California, in the Klamath region, at Cape Blanco, etc., but not abundant, in the gold washings of Cherokee, Butte Co.; in traces with gold in Rutherford Co., North Carolina; at St. François, Beauce Co., Quebec; at several points in British Columbia, thus on the Fraser river near Lillooet, also on Tranquille river and on Granite Creek, a branch of the Tulameen; further on the tributaries of the Yukon river. A mass weighing 104 grams, with G. = 10·45, and consisting of 46 p. c. platinum (anal. 27) and 54 chromite, was found near Plattsburgh, N. Y.

The metal platinum was brought from Choco, S. A., by Ulloa, a Spanish traveller in America, in the year 1735, and from Carthagena, by Charles Wood, who procured it in Jamaica. Ulloa speaks of specula made by the people of the country, of a peculiar metal, which Brownrigg says was “platina,” and the latter mentions a “pummel of a sword,” and other articles of platinum, received by him from Carthagena.

**Ref.**—[1] Cf. Eremeyev, Vh. Min. Ges., **14**, 155, 1879.

**21. IRIDIUM.** Gediegen Iridium *Breith., Berz.*. JB., **14**, 180, 1835, Ak. H. Stockh., 84, 1834. Platiniridium *Svanberg*, Berz. JB., **15**, 205, 1834.

Isometric. Observed forms[1]:

*a* (100, *i*-*i*) *d* (110, *i*) *o* (111, 1) *f* (310, *i*-3) $\theta$ (430, *i*-$\frac{4}{3}$)

Twins: tw. plane *o*, commonly in polysynthetic groups. Crystals rare, generally cubes. Usually in angular grains.

Cleavage: cubic, indistinct. Fracture hackly. Somewhat malleable. H. = 6–7. G. = 22·65–22·84[2]. Luster metallic. Color silver-white, with tinge of yellow on surface; gray on fracture. Opaque.

**Comp.**—Iridium with platinum and other allied metals.

**Anal.**—Svanberg:

| | Pt | Ir | Pd | Rh | Fe | Cu | Os | |
|---|---|---|---|---|---|---|---|---|
| 1. N. Tagilsk | 19·64 | 76·80 | 0·89 | — | — | 1·78 | — | = 99·11 |
| 2. Brazil | 55·44 | 27·79 | 0·49 | 6·86 | 4·14 | 3·30 | *trace* | = 98·02 |

Prinsep in a specimen from Ava in India found Ir 60, Pt 20; this is called *Avaite* by Heddle, Enc. Brit., **16**, 382, 1883.

**Obs.**—Occurs with the platinum of the Urals and Brazil; perhaps also with the California gold; Ava in Burma.

**Ref.**—[1] Erem., Vh. Min. Ges., **14**, 155, 1879. [2] Of cubic crystals 22·647–22·668, of octahedral 22·770–22·773 from Sukho-Visim, from Nevyansk, 22·805–22·836, Erem. l. c.

**22. IRIDOSMINE.** Ore of Iridium, consisting of Iridium and Osmium, *Wollaston*, Phil. Trans., 316, 1805 (Metals Iridium and Osmium, first announced by *Tennant*, Phil. Trans., 411, 1804). Native Iridium *Jameson*. Osmiure d'Iridium *Berz.*, Nouv. Syst. Min., 195, 1819. Osmium-Iridium *Leonh.*, Handb., 1821. Iridosmium; Osmiridium. Newjanskit, Sisserskit, *Haid.* Handb., 558, 1845.

Rhombohedral. Axis $\dot{c} = 1{\cdot}4105$; $0001 \wedge 10\bar{1}1 = 58° 27'$ Rose.

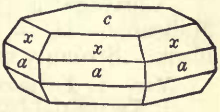
**Forms:** *c* (0001, *O*), *m* ($10\bar{1}0$, *I*), *r* ($10\bar{1}1$, *R*)[2], *z* ($01\bar{1}1$, $-1$)[2], *x* ($22\bar{4}3$, $\frac{4}{3}$-2).
Angles: $cx = {}^{*}62°$, $rr' = 95° 8'$, $xx' = 52° 24'$.

Rarely in hexagonal prisms; usually in irregular flattened grains.

Cleavage: *c* perfect. Slightly malleable to nearly brittle. H. = 6–7. G. = 19·3–21·12. Luster metallic. Color tin-white to light steel-gray. Opaque.

**Comp., Var.**—Iridium and osmium in different proportions. Two varieties depending on these proportions have been named as species, but they are isomorphous, as are also the metals themselves (Rose). Some rhodium, platinum, ruthenium, and other metals are usually present.

1



Ural, Rose.

**Var.**—1. *Nevyanskite.* Newjanskit Haid.; H. = 7; G. = 18·8–19·5. In flat scales; color tin-white. Over 40 p. c. of iridium.

2. *Siserskite.* Sisserskit Haid. In flat scales, often six-sided, color grayish white, steel-gray. G. = 20–21·2. Not over 30 p. c. of iridium. Less common than the light-colored variety.

**Anal.**—Deville and Debray, Ann. Ch. Phys., **56**, 481, 1859.

**Pyr., etc.**—At a high temperature the siserskite gives out osmium, but undergoes no further change. The nevyanskite is not decomposed and does not give an osmium odor. With niter, the characteristic odor of osmium is soon perceived, and a mass obtained soluble in water, from which a green precipitate is thrown down by nitric acid.

**Obs.**—Occurs with platinum in the province of Choco in South America; near Ekaterinburg, Zlatoust, and Kyshtimsk, in the Ural mountains; in auriferous and other drifts at various points as Bingera, Bathurst, etc., in New South Wales, Australia. Rather abundant in the auriferous beach-sands of northern California, occurring in small bright lead-colored scales, sometimes six-sided. Also traces in the gold-washings on the rivers du Loup and des Plantes, Canada.

**Ref.**—[1] Abh. Ak. Berlin, 97, 1849; Pogg., **29**, 452, 1833. [2] Lsx., also a more acute $m$-2 pyramid, Ber. nied. Ges., p. 99, 1882.

**23. PALLADIUM.** *Wollaston*, Phil. Trans. 1808.

Isometric. In minute octahedrons, Haid. Mostly in grains, sometimes composed of diverging fibers.

Ductile and malleable. H. = 4·5–5. G. = 11·3–11·8, Wollaston. Luster metallic. Color whitish steel-gray. Opaque.

**Comp.**—Palladium, alloyed with a little platinum and iridium.

**Pyr., etc.**—The blowpipe reactions of native palladium are undescribed. As prepared by Deville, it is the most fusible of the platinum metals. Oxidizes at a lower temperature than silver, but is not blackened by sulphurous gases.

**Obs.**—Palladium occurs with platinum in Brazil where masses of the metal are sometimes met with; reported from St. Domingo, also from the Urals (Breith., Berz. JB., **14**, 181, 1835).

**24. ALLOPALLADIUM.** Selenpalladium *Zinken*, Pogg., **16**, 496, 1829. Eugenesite *Adam*, Tabl. Min., 82, 1869.

Rhombohedral. In small six-sided tables, Zinken. Cleavage: basal perfect. Luster bright. Color nearly silver-white to pale steel-gray.

**Comp.**—Palladium under the rhombohedral system, if Zinken's early observations can be relied upon.

**Obs.**—From Tilkerode, in the Harz, in small hexagonal tables with gold.

**25. IRON.** Mars *Alchem.* Gediegen Eisen *Germ.* Jern *Swed.* Fer natif *Fr.* Ferro *Ital.* Hierro *Span.*

Isometric. Usually massive, rarely in crystals, $a$ (100), $o$ (111). Artificial crystals usually dendritic, with branches parallel to the cubic axes. Twins: tw. pl. $o$, as penetration-twins often repeated and producing embedded lamellæ parallel the faces of the trisoctahedron $p$ (221).

Cleavage: $a$ perfect; also a lamellar structure ∥ $o$ and ∥ $d$. Fracture hackly. Malleable. H. = 4–5. G. = 7·3–7·8 Luster metallic. Color steel-gray to iron-black. Strongly magnetic.

**Var.**—1. *Terrestrial;* 2. *Meteoric.*

1. **Terrestrial Iron.** Found in masses, occasionally of great size (up to 20 tons), as well as in small embedded particles, in basalt at Blaafjeld, Ovifak (or Uifak), Disco Island; also at Fortune Bay, Mellemfjord, Asuk, and other points on the same island, and at Niakornak, Disco Bay, and elsewhere on the coast of West Greenland.

The Disco iron was discovered in 1870 by A. E. Nordenskiöld, although the fact that native iron was used by the Greenland natives for knives, utensils, etc., was known much earlier (Captain Ross, 1819). It was supposed at first to be meteoric, but its terrestrial nature has since been placed beyond doubt. It is uncertain, however, whether the iron was brought up as such by the basalt or whether it was reduced by the action of the carbonaceous shales through which the basalt passed; the latter seems most probable, and is confirmed by the presence of graphite and graphitic feldspar in the basalt.

The iron varies in character from the exterior or oxidized crust, to that which is compact and malleable; for the most part the iron oxidizes and disintegrates rapidly upon exposure, in part owing to a deliquescent iron chloride. Some of this iron exhibits when etched a crystalline structure which somewhat resembles that common with meteoric iron (see beyond).

Besides the Greenland irons, some other occurrences, usually classed as meteoric, may be in fact terrestrial; *e.g.*, the Santa Catharina iron of Brazil discovered in 1875.

**Analyses** of various Greenland irons, 1–12, Lorenzen[1]:

For other analyses see the authors quoted[1].

A nickeliferous metallic iron, called *awaruite* Skey, (Trans. N. Zeal. Inst., **18**, 401, 1885,) occurs in the drift of the Gorge river, which empties into Awarua Bay on the west coast of the south island of New Zealand. It is associated with gold, platinum, cassiterite, chromite, and magnetite, and has probably been derived from a partially serpentinized peridotyte. It has H. = 5, G. = 8·1. Composition $FeNi_2$ = Iron 32·3, nickel 67·7 = 100. Compare anal. 14, p. 30. Analysis by W. Skey yielded:

G. = 8·1 Fe 31·02 Ni 67·63 Co 0·70 S 0·22 $SiO_2$ 0·43 = 100

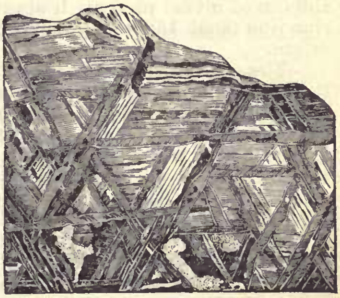
Native iron also occurs sparingly in some basalts (Andrews *et al.*); in pyrite nodules in a Keuper limestone at Mühlhausen in Thuringia; in the Plänerkalk at Chozen in Bohemia (ancient meteorite?) Also reported from gold or platinum washings at various points, but they are not all free from doubt: thus in the Urals, Brazil, Montgomery Co., Va., Burke Co., N. C., Camp Creek, Montana. Reported from shale near New Brunswick, New Jersey. Masses of metallic iron locally reduced from clay ironstone by the burning of a lignite bed have been noted 70 miles above Edmonton on the North Saskatchewan river, Alberta.

Bahr has observed grains of native iron in a fragment of petrified wood. The iron was mixed with limonite and organic matter, and is supposed to have been produced by the deoxidation of a salt of iron by the organic matter of the wood. He calls the iron *sideroferrite*.

SIDERAZOT *O. Silvestri*, Pogg. Ann., **157**, 165, 1876. Silvestrite *A. D'Achiardi*, I Metalli, **2**, 84, 1883. A product of volcanic eruption, observed at Mt. Etna after the eruption of Aug., 1874, as a very thin coating on lava. Non-crystalline. Luster metallic, resembling steel. Slowly attacked by acids. An analysis gave: N 9·14, Fe 90·86 = 100, which corresponds to $Fe_5N_2$ which requires: Nitrogen 9·11, iron 90·89 = 100. This is the composition (Frémy) of the artificial iron nitride.

2. **Meteoric Iron.** Native iron also occurs in most meteorites, forming in some cases (*a*) the entire mass; also (*b*) as a spongy, cellular matrix in which are imbedded grains of chrysolite or other silicates; (*c*) in grains or scales disseminated more or less freely throughout a stony matrix. Rarely a meteorite consists of a single crystalline individual (Braunau) with numerous twinning lamellæ ∥ *o* (cf. above).

1.



Glorieta Mt., New Mexico.

Cubic cleavage sometimes observed; also an octahedral, less often dodecahedral lamellar structure. Etching with dilute nitric acid (or iodine) commonly develops a crystalline structure[2, 3], usually consisting of lines or bands crossing at various angles according to the direction of the section, at 60° if ∥ *o*, 90° ∥ *a*. etc. These figures (f. 1) are called *Widmanstätten figures*, because first described by Widmanstätten in 1808. They are formed by the edges of crystalline plates of the nickeliferous iron in different conditions, as shown by the fact that they are differently attacked by the acid (see also analyses below). These plates are usually parallel to the octahedral faces. Reichenbach named them "Balkeneisen" or *kamacite*, from *κάμαξ*, *pole* or *shaft*. "Bandeisen" or *tænite*, from *ταινία*, *band*, and "Fülleisen" or *plessite*; the first forms the broader plates marking the structure, supposed to be of purer iron and hence more readily attacked; the second forms thin plates bounding the first, rich in nickel, appearing also in thin lamellæ; the third is the ground-mass. Enclosed in the "Balkeneisen" are sometimes areas of a white iron, resisting acids, and having a brilliant luster; this is Reichenbach's "Glanzeisen" or *lamprite*, from *λαμπρός* *lustrous*. Irons with cubic structure and with twinning lamellæ (*e.g.*, Braunau) have a series of fine lines corresponding to these developed by etching (*Neumann lines*). A damascene luster is also produced in some cases, due to quadrilateral depressions. From the distinctly octahe dral iron, showing the figures most perfectly, there are many gradations to the irons which show no distinct crystalline structure at all upon etching.

The exterior of masses of meteoric iron is usually more or less deeply pitted with rounded thumblike depressions, and the surface at the time of fall is covered with a film of iron oxide in fine ridges showing lines of flow due to the melting caused by the heat developed by the resistance of the air; this film disappears when the iron is exposed to the weather.

**Comp.**—Meteoric iron is always alloyed with nickel, which is usually present in amounts varying from 5 to 10 p. c.; small amounts of other metals, as cobalt, manganese, tin, copper, chromium, are also often present. Occluded gases can usually be detected. Wright obtained from the Arva iron 44 volumes of mixed gases by heating up to low redness[4].

X = silicates, insol., etc. Sch. = Schreibersite. Gr. = Graphite.

The Octibbeha iron or *octibbehite* (anal. 14, supposing this correct) is exceptional in the amount of nickel present; it approximates to the terrestrial awaruite (p. 29). The Santa Catharina iron (anal. 15) is also remarkably rich in nickel, but this is regarded by some as of terrestrial origin.

The composition of the portions of the meteoric iron to whose separate formation the structure of the Widmanstätten figures is due has been only partially determined. Meunier assigns to kamacite the formula $Fe_{14}Ni$ with G. = 7·652; to tænite $Fe_6Ni$ with G. = 7·380; and to plessite $Fe_{10}Ni$ with G. = 7·850. Reichenbach assigned to plessite the formula $Fe_{28}Ni_5$. Analyses: 1, 2, 4, Meunier, Météorites, 48–50, 1884. 3, Reichenbach, Jr, Pogg., **114**, 258, 1861. See also p. 1037.

Weinschenk obtained for thin lamellæ from the Arva iron: Fe 71·50, Ni 26·82, Co 1·68 = 100, corresponding to $Fe_5(Ni,Co)_2$ and approximating to the edmonsonite (see below) of Flight. He thinks these tænite lamellæ are really made up of two compounds, $Fe_8Ni$ and $Fe_5Ni_2$. The subject obviously requires much more investigation.

The following are other more or less well defined iron compounds from meteoric irons:

EDMONSONITE *W. Flight*, Phil. Trans., 888, 1882.

An iron-nickel alloy forming fine lines in the Widmanstätten figures of the Cranbourne, Victoria, meteoric iron. Analysis: Fe 70·14, Ni 29·74 = 99·88. Flight identifies this with the *meteorin* of Abel, see Zimmermann, Jb. Min., 557, 1861. Named after George Edmonson, Head Master of Queenwood College, Hampshire.

CHALYPITE *Shepard*, Am. J. Sc., **43**, 28, 1867.—A compound of iron and carbon found by Forchhammer as a leading constituent of the Niakornak iron. The carbon varied from 7–11 p. c. Meunier uses the name (Ann. Ch. Phys., **17**, 36, 1869; cf. also Météorites, p. 52), and introduces another, Campbellite, for a compound with C = 1·50 p. c., assumed by him as present in the Campbell Co., Tenn., meteoric iron, which was analyzed by J. L. Smith, Am. J. Sc., **19**, 159, 1855.

COHENITE *E. Weinschenk*, Ann. Mus. Wien, **4**, 94, 1889.

In crystals, probably isometric but distorted. Brittle. H. = 5·5–6. G. = 6·977. Luster metallic. Color tin-white, becoming bronze-yellow on exposure. Composition $(Fe,Ni,Co)_3C$. Analysis, after deducting a little schreibersite: $\frac{2}{2}$ Fe 89·88, Ni(Co) 3·71, C 6·41, Sn, Cu *tr.*=100. Named after Dr. E. Cohen of Greifswald.

SCHREIBERSITE *Haid.*, Haid. Ber., **3**, 69, 1847. Phosphornickeleisen *Germ.*

Crystallized; also in steel-gray folia and grains. In some cases brittle; again in flexible folia. H. = 6·5. G. = 7·01–7·22, Haid. Magnetic.

A phosphide of iron and nickel, $(Fe,Ni)_3P$, in part $Fe_2NiP$ = Phosphorus 15·4, iron 55·5, nickel 29·1 = 100. Analyses: 1, Patera, Haid. Ber., l. c., and Am. J. Sc., **8**, 439, 1849. 2, Fisher, Am. J. Sc., **19**, 157, 1855. 3–5, J. L. Smith, ib. 6, Meunier, Ann. Ch. Phys., **17**, 43, 1869. 7, W. Flight, Phil. Trans., 892, 1882. 8, Cohen, Jb. Min., **1**, 219, 1889.

Flight gives analyses of other compounds corresponding nearly to $Fe_9Ni_2P_4$ and $(Fe,Ni)_4P$. An iron-nickel phosphide from the Deesa iron gave Meunier: P 10·29, Fe 60·00, Ni 26·75=97·04.

Schreibersite is named after Director Carl Fr. A. von Schreibers of Vienna (1775–1882). On Schreibersite of Shepard, see p. 79.

RHABDITE *Rose.*—A phosphide of iron and nickel, occurring in minute tetragonal prisms distributed parallel to the cubic edges in the meteoric irons of Braunau, Seeläsgen, Misteca. A similar compound occurs in the Cranbourne, Australia, iron, in brittle square prisms, with G. = 6·33–6·78. Analysis, Flight, Phil. Trans., 891, 1882:

$\frac{2}{2}$ P 12·95 Fe 49·34 Ni 38·24 = 100·53

An iron phosphide, formed by combustion in the coal mines of Commentry, France, is referred here by Mallard. Tetragonal. Axis $\dot{c}$ = 0·4880. Forms: *a* (100), *m* (110), *e* (101); 001 ∧ 101 = 26° 1′; *me* = *71° 56′, *ee′* = 36° 8′. Hard. G. = 7·14. Luster metallic. Color steel-gray. Brittle. Magnetic. Analysis, Carnot: P 12·10, Fe 84·28, As 1·65, S 1·75, C *tr.*=99·78. Bull. Soc. Min., **4**, 230, 1881.

APPENDIX.—Meteorites are usually classified according to the amount of iron they contain, as follows:

(*a*) *Meteoric iron* proper, *siderites* or *holosiderites* of Daubrée, consisting of iron alone with only occasional veins, grains or nodules of troilite, carbon as graphite or diamond (cf. cliftonite, p. 6), schreibersite, daubreelite, etc. Iron protochloride, lawrencite, is often present, and exudes forming drops of $FeCl_3$ on the surface and often leading to rapid disintegration of the mass.

Upward of one hundred localities of these have been noted, and in a few instances they have been seen to fall.* Some of the masses are very large; the *Butcher* irons of the Bolson de Mapini in the States of Chihuahua and Coahuila, Mexico, include several masses, one estimated to weigh 5 tons. The Red River, Texas, iron (anal. 7) weighs 1635 pounds.

(*b*) *Siderolites* or *syssiderites* of Daubrée, consisting of a more or less continuous spongy mass of iron with embedded grains chiefly of chrysolite, like the Pallas Iron of Krasnoyarsk, Siberia

---

* The most important cases are Agram, Croatia, May 26, 1751; Charlotte, Tenn., Aug. 1, 1835; Braunau, Bohemia, July 14, 1847; Tabarz, Saxony, Oct. 18, 1854; Rowton, Shropshire, England, April 20, 1876; Mazapil, Mexico, Nov. 27, 1885; Cabin Creek, Johnson county, Arkansas, March 22, 1886.

(hence called by Rose *pallasites*), which was brought to St. Petersburg by Pallas in 1772 and which weighed originally 1600 pounds. Masses of a meteorite, closely resembling the Pallas Iron, were found in Kiowa Co., Kansas, in March, 1890; they aggregated from 1000 to 1200 lbs. The siderolites graduate through the kinds in which the iron is more scattered (*mesosiderites* of Rose), though forming a large part of the whole, to the meteoric stones.

(*c*) *Meteoric stones, sporadosiderites* of Daubrée, in which iron is more or less disseminated through the mass, including as named by Daubrée the *polysiderites*, *oligosiderites* and *cryptosiderites*. Those stones which contain no iron are called by him *asiderites*.

Meteoric stones have also been classified according to the silicates present in largest amount, and a large number of names introduced, chiefly taken from the names of localities, by Rose, Shepard, Tschermak, Meunier, Wadsworth and others. Many stones are characterized by the presence often to large extent of *chondrules*, or small spherical grains from the size of a cherry down, consisting usually of chrysolite or enstatite (cf. these species), the latter often with eccentric radiated structure—these stones are hence called *chondrites*.

Specimens of two hundred and fifty independent occurrences of meteoric stones have been preserved, and for most of them the date and often the circumstances of the fall are known. In some cases large numbers of stones are the result of a single fall, as that of Pultusk, Poland, in Jan. 30, 1868. Of the Estherville, Iowa, meteorite (siderolite) in addition to large masses weighing 450, 200, 95 lbs., and others, about 60 pounds of minute individuals were picked up, mostly weighing less than an ounce and the smallest of the size of shot, these last chiefly iron. Another fall, remarkable for the number of small stones found, was that of Winnebago Co., Iowa, on May 2, 1890.

[2] On the crystalline structure of iron in general, see Tschermak, Ber. Ak. Wien, **70** (1), 449, 1874, who also gives the early literature of the subject. Also, [3] on the Widmanstätten and related figures, see Breithaupt, Schweig. J., **52**, 172, 1828, who gives the history of the name; also Neumann, Nat. Abh. Haid., **3**, pt. 2, 45, 1850; Reichenbach, Pogg., **114**, 99, 250, 264, 477, 1861; Rose, see below; Brezina, Denkschr. Ak. Wien, **43**, 1880, **44**, 1881; Huntington, Proc. Amer. Acad., May 12, 1886, or Am. J. Sc., **32**, 284, 1886.

[4] On the gases occluded in meteorites, see Graham, Proc. Roy. Soc., **15**, 502, 1867; Mallet, ib., **20**, 365, 1872; Wright, Am. J. Sc., **9**, 294, 459, **10**, 44, 1875; Flight, Phil. Trans., 1882; Ansdell and Dewar, Proc. Roy. Soc., **40**, 549, 1886.

[5] On the classification of meteorites and the subject in general: Reichenbach, Pogg., **107**, 155, 1859; Rose, Beschreibung und Eintheilung der Meteoriten, etc., Abh. Ak. Berlin, 23, 1863; Daubrée, C. R., **65**, 60, 1867; Shepard, Am. J. Sc., **43**, 22, 1867 (and others earlier); Tschermak, Ber. Ak. Wien, **71** (1), 1875, **75** (1), 1877, **88** (1), 1883; Brezina (see below). Also Die mikroskopische Beschaffenheit der Meteoriten, 1883 et seq. S. Meunier, Météorites, 532 pp., Paris 1884 (Encycl. Chem., vol. **2**, Frémy); Wadsworth, Lithological Studies, Mem. Mus. Zool., Cambridge **11**, 1884, who gives many observations on microscopic structure, also tables of analyses.

On the spectra of meteorites, discussion of origin, etc., see Lockyer, Nature, 1889; also on the latter subject, Newton, Tschermak and others.

See also Rg., Min. Ch., 901, 952, 1860, and Die chemische Natur der Meteoriten, Abh. Ak. Berlin, 75, 1870, 1, 1879; Buchner. Die Meteoriten, etc., 202 pp., Leipzig, 1863; Daubrée, Études synthétiques de géologie expérimentale, Paris; Early papers of importance include those by Chladni, Howard, Biot, Carl von Schreibers, Haidinger, etc.; also, later, Tschermak, Daubrée, Maskelyne, Brezina, J. Lawrence Smith (collected in Original Researches, etc., 1884); W. Flight (collected in "A Chapter on Meteorites," 1887), and many others.

For a list of meteorites with localities, dates, etc., see the catalogues of the Vienna collection (Brezina, Jb. G. Reichs., 151–276, 1885), of the British Museum (Fletcher, 1888), of the Muséum d'Histoire Naturelle, Paris (Daubrée, 1889), and others. A catalogue of the Yale collection (E. S. D.) is given in Am. J. Sc., **32**, appendix, 1886; one of the Harvard collection by O. W. Huntington in Proc. Am. Acad., **23**, 1887.

## II. SULPHIDES, SELENIDES, TELLURIDES, ARSENIDES, ANTIMONIDES.

The sulphides fall into two Groups according to the character of the positive element.

**I. Sulphides, Selenides, Tellurides of the Semi-Metals.**

**II. Sulphides, Selenides, Tellurides, Arsenides, Antimonides of the Metals.**

---

### I. Sulphides, Selenides, Tellurides of the Semi-Metals, Arsenic, Antimony, Bismuth; also Molybdenum.

Crystals short prismatic. Faces in prismatic zone striated vertically. Also granular, coarse or fine; compact; as an incrustation.

Cleavage: *b*, rather perfect; *c*, *a*, *m*, less so; also *l* (Dx.). Fracture small conchoidal. Sectile. H. = 1·5–2. G. = 3·556. Luster resinous. Color aurora-red or orange-yellow. Streak varying from orange-red to aurora-red. Transparent—translucent. Optically −. Double refraction strong. Ax. plane ∥ *b*. Bx $\wedge \dot{c} = +11°$. Dispersion inclined, strong. $2H_r = 96° 20'$, $2H_y = 92° 58'$, Dx.[8].

**Comp.**—Arsenic monosulphide, AsS = Sulphur 29·9, arsenic 70·1 = 100.

**Pyr., etc.**—In the closed tube melts, volatilizes, and gives a transparent red sublimate; in the open tube (if heated very slowly) sulphurous fumes, and a white crystalline sublimate of arsenic trioxide. B.B. on charcoal burns with a blue flame, emitting arsenical and sulphurous odors. Soluble in caustic alkalies.

**Obs.**—Often associated with orpiment; occurs with ores of silver and lead, at Felsöbánya and Kapnik in Hungary, Nagyág in Transylvania, at Joachimsthal in Bohemia, at Schneeberg in Saxony, at Andreasberg in the Harz; at Tajowa in Hungary, in beds of clay; Binnenthal, Switzerland, in dolomite; at Wiesloch in Baden, in the Muschelkalk; on quartz in phyllyte at Kreševo, Bosnia; near Julamerk in Kurdistan; in Vesuvian lavas, in minute crystals, and the solfataras near Naples; also in the trachytic region of Tolfa near Rome, in the calcite veins of a micaceous sandstone. Strabo speaks of a mine of *sandaraca* (the ancient name of this species) at Pompeiopolis in Paphlagonia.

In the U. S., in seams in a sandy clay beneath the lava in Iron county, Utah; also in California, 40 miles from the Needles, San Bernardino Co., and in Trinity Co., in calcite; Norris Geyser Basin, Yellowstone National Park, where it occurs with orpiment as a deposition from the hot waters.

The name *realgar* is from the Arabic Rahj al ghār, *powder of the mine*.

**Alt.**—Changes on exposure to light to orpiment ($As_2S_3$) and arsenolite ($As_2O_3$).

**Artif.**—Obtained in monoclinic crystals by Sénarmont, C. R., **32**, 411, 1851.

**Ref.**—[1] Quoted by Dx., Ann. Ch. Phys., **10**, 422, 1844; with Naumann the vertical axis has one-half this length. [2] See Hbg., Min. Not., **1**, 14, 1856; **3**, 3, 1860; also Mlr., Min. 177, 1852, and earlier Scc., Mem. G. Camp., 110, 1849; Lévy, Min. Heul., **3**, 277, 1837.

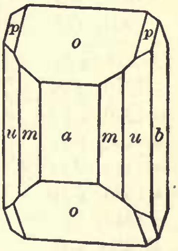
| *oo'* | = | *96° 23′ | | | | | | | | | |

Crystals small and rarely distinct. Usually in foliated or columnar masses; sometimes with reniform surface.

1.



Cleavage: *b* highly perfect, cleavage face vertically striated; *a* in traces; gliding-plane 001 (Mgg., cf. stibnite). Sectile. Cleavage laminæ flexible, inelastic. H. = 1·5–2. G. = 3·4–3·5. 3·480 Mohs. Luster pearly on *b* (cleavage); elsewhere resinous. Color lemon-yellow of several shades; streak the same, but paler. Subtransparent—subtranslucent. Optically +. Ax. pl. ∥ *c*. Bx ⊥ *a*. Ax. angle large, Dx.[5]

**Comp.**—Arsenic trisulphide, $As_2S_3$ = Sulphur 39·0, arsenic 61·0 = 100.

**Pyr., etc.**—In the closed tube, fuses, volatilizes, and gives a dark yellow sublimate; other reactions the same as under realgar. Dissolves in aqua regia and caustic alkalies.

**Obs.**—Orpiment in small crystals is embedded in clay at Tajowa, near Neusohl in Upper Hungary. It is usually in foliated and fibrous masses, and in this form is found at Moldawa in the Banat; at Kapnik and also Felsöbanya in Hungary it exists in metalliferous veins, associated with realgar and native arsenic; at Kreševo, Bosnia, on quartz crystals in a micaceous phyllyte; at Hall in the Tyrol it is found in gypsum; at Wiesloch in Baden in the Muschelkalk; at St. Gothard in dolomite; with calcite in a micaceous sandstone in the trachytic region of Tolfa, near Civita Vecchia, Italy; at the Solfatara near Naples it is the result of volcanic sublimation; in Fohnsdorf, Styria, found in brown coal. Near Julamerk in Kurdistan there is a large Turkish mine. Occurs also at Acobambillo, Peru. Small traces are met with at Edenville, Orange Co., N. Y., on arsenical iron. Occurs with realgar in seams in compact clay beneath lava in Iron county, Utah. Occurs among the deposits of the Steamboat Springs, Nevada (Becker); also with realgar in the Yellowstone Park.

The name orpiment is a corruption of its Latin name auripigmentum, "*golden paint,*" given in allusion to the color, and also because the substance was supposed to contain gold.

**Artif.**—A common artificial product, sometimes called King's yellow (Königsgelb *Germ.*).

**Ref.**—[1] Min., **2**, 613, 1824; some authors make *m* = 120, with Groth *m* = 320. [2] Phillips gives a doubtful prism *g* with *gu* = 2° 6′ (6·13·0?), Min., 277, 1823; for *β* he gives *βo* = 34° 10′. [3] Mlr. Min., 176, 1852. [4] Knr., Földt. Közl., **13**, 381, 1883. [5] Bull. Soc. Min., **5**, 108, 1882.

DIMORPHITE. Dimorfina *A. Scacchi*, Mem. Geol. Campania, Napoli, 116, 1849.

Minute (to ½ mm.) orange-yellow crystals with adamantine luster. H. = 1·5. G. = 3·58. A sulphide of arsenic ($As_4S_3$ suggested). From a fumarole of the Solfatara, Phlegræan fields. Described as occurring in two types. TYPE A with $\breve{a} : \bar{b} : \grave{c} = 0{\cdot}895 : 1 : 0{\cdot}776$, and the forms *C* (100), *B* (010), *A* (001), *o* (110), *o*2 (120), *e* (011), *m* (111). TYPE B with $\breve{a} : \bar{b} : \grave{c} = 0{\cdot}907 : 1 : 0{\cdot}603$, and the forms *C* (100), *B* (010), *o*2 (120), *i* (101), *e* (011), *m* (111). In the positions taken the lateral axes are nearly equal, while the vertical axes are as 9 : 7 (or 5 : 4 or 4 : 3 approx.). Type A, however (see 4th ed. p. 32), is near orpiment in habit and angles and probably identical with it. This is seen when the crystals are placed so that $C$, $B$, $A$, $o$, $o2$, $e$, $m$ correspond to $a$, 001, $b$, $o$, 102, 021, $v$. Then $\breve{a}:\bar{b}:\dot{c} = 0{\cdot}5765 : 1 : 0{\cdot}6441$. The angles for dimorphite (Scc., meas.) and orpiment (calc.) are respectively: $oo'$ = *96° 20′, 96° 33′; $102 \wedge \bar{1}02$ = 58° 19′, 58° 28′; $b \wedge 021$ = 38° 5′, 36° 32′; $av$ = 55° 37′, 56° 19′, $bv$ = *49° 20′, 48° 2′.

The relations of type B are less clear; in the position corresponding to the above, the planes $C$, $B$, $o2$, $i$, $e$, $m$ may perhaps be $a$, $b$, 102, 250, 052, 252. The angles are then for dimorphite (Scc., meas.) and orpiment (calc.) respectively: $102 \wedge \bar{1}02$ = 58° 12′, 58° 28′; $010 \wedge 052$ = 31° 9′, 30° 39′, etc.

Or if placed so that $e$ dimorphite ($ee$ = 62° 18′) corresponds to $m$ orpiment ($mm'''$ = 62° 17′), then, as shown by Kenng. (Jb. Min., 537, 1870), the planes become 001, $b$, 083, 403, $m$, 443. In the latter case the correspondence of angle is closer.

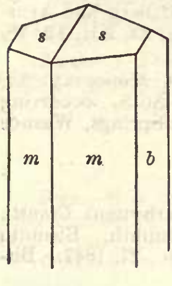
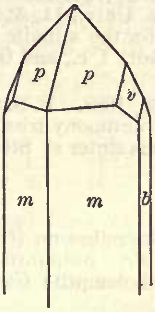
Crystals prismatic, often acutely terminated; vertical planes striated or deeply furrowed longitudinally; crystals often curved, bent in knee-shaped forms or twisted, especially in the axial plane $\bar{b} : \grave{c}$. Common in confused aggregates of acicular crystals, also in radiating groups; massive, coarse or fine columnar, less often granular to impalpable.

1.



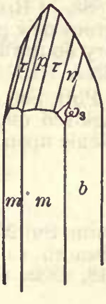
California.

2.



Hungary.

3.

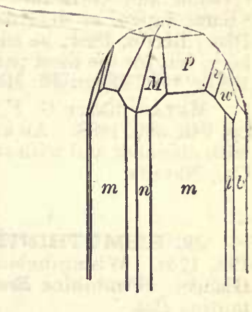


Japan.

4.

Kapnik, Knr.

5.

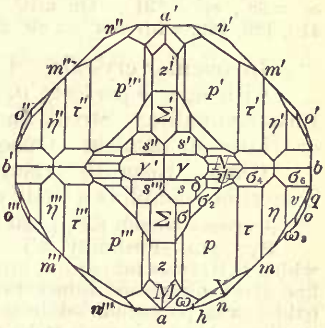


Felsöbánya, Knr.

Cleavage: *b* highly perfect, the face often striated or bent transversely; also *a*, *m* imperfect; *c*, ⊥ to cleavage, a gliding-plane[8]. Crystals flexible under moderate pressure in the plane $\bar{b} : \grave{c}$. Slightly sectile. Fracture small subconchoidal. H. = 2. G. = 4·52–4·62. Luster metallic, highly splendent on cleavage or fresh crystalline surfaces. Color and streak lead-gray, inclining to steel-gray: subject to blackish tarnish, sometimes iridescent.

**Comp.**—Antimony trisulphide, $Sb_2S_3$ = Sulphur 28·6, antimony 71·4 = 100. Sometimes auriferous, also argentiferous.

6.



Japan[4].

**Pyr., etc.**—Fuses very easily (at 1), coloring the flame greenish blue. In the open tube sulphurous ($SO_2$) and antimonial ($Sb_2O_3$) fumes, the latter condensing as a white sublimate which B.B. is non-volatile. On charcoal fuses, spreads out, gives sulphurous fumes, and coats the coal white with antimony trioxide; this coating treated in R.F. volatilizes and tinges the flame greenish blue. When pure perfectly soluble in hydrochloric acid; in nitric acid decomposed with separation of antimony pentoxide.

**Obs.**—Occurs with quartz in beds or veins in granite and gneiss, often accompanied with various other antimony minerals produced by its alteration. Also associated in metalliferous deposits with sphalerite, galena, cinnabar, barite, quartz; sometimes accompanies native gold.

Met with in veins at Wolfsberg, in the Harz; at Bräunsdorf, near Freiberg; at Přibram; at Casparizeche, near Arnsberg, Westphalia; Felsöbánya, Schemnitz, and Kremnitz, in Hungary, where it often occurs in diverging prisms, several inches long, accompanied by crystals of heavy spar and other mineral species; at Pereta, in Tuscany, in crystals; in Ekaterinburg, in the Ural; in Dumfriess-shire, fibrous and laminated; in Cornwall, abundant near Padstow and Tintagel; also crystallized at Wheal Boys; at Hare Hill, in Scotland; in Perthshire. Also found at different Mexican mines. In Algeria. Also abundant in Borneo. In Victoria and New South Wales. Magnificent groups of splendent crystals up to 20 inches in length have been brought from the extensive antimony mines in the Province of Iyo, island of Shikoku, Japan.

In the United States it occurs sparingly at Carmel, Penobscot Co., Me.; at Cornish and Lyme, N. H.; at "Soldier's Delight," Md.; as a vein of considerable extent in Sevier county, Ark.; abundant in California at San Emigdio, Kern county, and near Alta, Benito Co.; also with cinnabar at the Stayton mines, the Knoxville district and elsewhere; in the Humboldt mining region in Nevada, and usually argentiferous; also in the mines of Aurora, Esmeralda Co., Nevada; in Iron county, southern Utah; fine granular and compact in Cœur d'Alene Mts., Shoshone county, Idaho. Also found in New Brunswick in Prince William, York county, 20 m. at Fredericton; in Rawdon township, Hants Co., N. S.; Foster's Bar, Fraser river, B. C.

This ore was employed by the ancients for coloring the hair, eyebrows, etc., to increase the apparent size of the eye; whence they called the ore platyophthalmon (*πλατυόφθαλμον*), from *πλατύς*, *broad*, and *ὀφθαλμός*, *eye*.

**Alt.**—Changes on exposure by partial oxidation to kermesite ($2Sb_2S_3.Sb_2O_3$), and by further oxidation to *valentinite* ($Sb_2O_3$). *Antimony ochre* also results from its alteration.

**Artif.**—Obtained in crystals by several methods, cf. Fouqué-Lévy, Synth. Min., 317, 1882.

**Ref.**—[1] Japan, Am. J. Sc., **26**, 214, 1883. [2] See Krenner for early authorities, etc., and many new planes, Ber. Ak. Wien, **51**, 436, 1865; also Gdt., Index, **1**, 221, 1886, for a careful revision and correction. [3] Slg., Arnsberg, Jb. Min., **1**, 135, 1880. [4] E. S. D., Japan, l. c. [5] Knr., Japan, Földt. METASTIBNITE *G. F. Becker*, Am. Phil. Soc., **25**, 168, 1888. U. S. G. Surv., Monograph 13, pp. 343, 389, 1888. An amorphous brick-red deposit of antimony trisulphide, $Sb_2S_3$, occurring with cinnabar and with sulphide of arsenic upon siliceous sinter at Steamboat Springs, Washoe Co., Nevada.

**29. BISMUTHINITE.** Visimutum Sulphure mineralisatum (fr. Riddarhyttan) *Cronst.*, 193, 1758. Wismuthglanz *Germ.* Bismuth sulphuré *Fr.* Sulphuret of Bismuth. Bismuth Glance. Bismuthine *Beud.*, Tr., **2**, 418, 1832. Bismutholamprite *Glock.*, Syn., 27, 1847. Bismutina *Ital.*

Orthorhombic. Axes $\breve{a} : \bar{b} : \dot{c} = 0{\cdot}9679 : 1 : 0{\cdot}9850$ Groth[1].
$100 \wedge 110 = 44° \; 4'$, $001 \wedge 101 = 45° \; 30'$, $001 \wedge 011 = 44° \; 34'$.

**Forms**[1]: *a* (100, *i*-ī), *b* (010, *i*-ĭ); *m* (110, *I*), *e* (130, *i*-3̆), *r* (101, 1-ī). Angles: $mm''' = {*}88° \; 8'$, $ee' = 38°$, $rr' = {*}91°$. On artif. cryst. see Phillips[2] and Rose[3]; the latter observed *a, b, m*, also 410, 120, 140, with $mm''' = 89° \; 20'$.

In acicular crystals. Usually massive, with a foliated or fibrous structure.

Cleavage: *b* perfect; *a, m* imperfect. Somewhat sectile. H. = 2. G. = 6·4–6·5. Luster metallic. Streak and color lead-gray, inclining to tin-white, with a yellowish or iridescent tarnish. Opaque.

**Comp.**—Bismuth trisulphide, $Bi_2S_3$ = Sulphur 18·8, bismuth 81·2 = 100. Sometimes contains a little copper and iron.

Analyses see 5th Ed., p. 30. Forbes gives for the Bolivia mineral G. = 7·2.

**Pyr., etc.**—Fusibility = 1. In the open tube sulphurous fumes, and a white sublimate which B.B. fuses into drops, brown while hot and opaque yellow on cooling. On charcoal at first gives sulphurous fumes; then fuses with spirting, and coats the coal with yellow bismuth oxide; with potassium iodide a bright red coating of bismuth iodide is obtained. Dissolves readily in hot nitric acid, and a white precipitate falls on diluting with water.

**Obs.**—Accompanies molybdenite and apatite in quartz, at Brandy Gill, Carrock Fells, in Cumberland, having a foliated structure; near Redruth; at Botallack, near Land's End; at Herland Mine, Gwennap; with childrenite, near Callington; at Lanescott mine, near St. Austell. In France at Meymac, Corrèze; at Johanngeorgenstadt, Altenberg, Schneeberg, in limestone; at Wittichen, Baden; with cerium ore at Riddarhyttan, Sweden; at the San Baldomero mine, near Sorata, Bolivia, foliated, massive, and acicular; also from Cerro de Tazna.

Occurs with gold, pyrite, and chalcopyrite in Rowan Co., N. C., at the Barnhardt vein. Reported by Shepard to have been found with chrysoberyl at Haddam, Ct. Sparingly at Willimantic, and Portland, Conn., in part altered to bismuth carbonate. Abundantly with almandine garnet and barite in the Granite mining district, Beaver county, Utah; also at Oasis, Mono Co., and in northeastern Fresno Co., Cal.

**Alt.**—Occurs altered to anhydrous bismuth carbonate, cf. bismutosphærite, 290.

**Artif.**—Obtained in crystals by Sénarmont *et al.*, cf. Fouqué-Lévy, Synth. Min., 318, 1882.

**Ref.**—[1] Tazna, Bolivia, Zs. Kr., **5**, 252, 1880. [2] Phil. Mag., **2**, 181, 1827. [3] Pogg., **91**, 401, 1854.

BOLIVITE *Domeyko*, 6th App. Min. Chili, p. 19, 1878. Described as a bismuth oxysulphide, $Bi_2O_3$ with $Bi_2S_3$. It is derived from the oxidation of the sulphide bismuthinite, and is of very uncertain composition. The description would apply to a mixture of the oxide with the original sulphide, which is enclosed in it. The uncertain character of the mineral seems to have been later accepted by Domeyko, for in the 3d Ed. of his Mineralogy (1879, p. 304) the occurrence is only mentioned briefly, and without any name. Locality, mines of Tazna, in the province of Chorolque, Bolivia.

**30. GUANAJUATITE.** Una nueva especie mineral de bismuto *Castillo*, Naturaleza **2**, 274, 1873; Jb. Min., 225, 1874. Guanajuatite *V. Fernandez*, "La República" of Guanajuato, July 13, 1873. Selenwismuthglanz *Frenzel*, Jb. Min., 679, 1874. Frenzelite 2nd Append. Dana's Min., 22, 1875. Castillite *Domeyko*, Min. Chili, p. 310, 1879.

Orthorhombic, isomorphous with stibnite; $mm''' = 90°$ approx. In acicular prismatic crystals, striated longitudinally, often forming semi-compact masses. Also massive with granular, foliated or fibrous structure.

Cleavage: *b* distinct. Somewhat sectile. H. = 2·5–3·5. G. = 6·25–6·62. Luster metallic. Color bluish gray. Streak gray, shining.

**Comp.**—Bismuth selenide, $Bi_2Se_3$ = Selenium 36·3, bismuth 63·7 = 100; a small part of the selenium is replaced by sulphur.

**Anal.**—1, Frenzel, Jb. Min., 679, 1874. 2, Mallet, Am. J. Sc., **15**, 294, 1878, after deducting 6·72 p. c. halloysite and 0·56 $SiO_2$.

| | Se | S | Bi |

| 2. | 34·33 | 0·66 | 65·01 = 100 |

**Pyr.**—B.B. on charcoal fuses with a blue flame, giving a strong odor of selenium; with potassium iodide on charcoal a red coating of bismuth iodide. Decomposed by aqua regia on slow heating.

**Obs.**—From the Santa Catarina mine, Sierra de Santa Rosa, near Guanajuato, Mexico. Associated with native bismuth and pyrite.

SILAONITE *V. Fernandez* and *S. Navia*, "La República," Guanajuato, Mexico, Dec. 25, 1873. A massive, bluish gray mineral. H. = 2·75. G. = 6·43–6·45. Described as having the composition $Bi_3Se$. Shown subsequently by Fernandez, and also by H. D. Bruns (Chem. News, **38**, 109, 1878), to be a mixture of guanajuatite and native bismuth, and not a homogeneous mineral.

---

**31. TETRADYMITE.** Ore of Tellurium (fr. Tellemark) *Esmark*, Trans. G. Soc., **3**, 413, June 1, 1815. Tellurwismuth (fr. Riddarhyttan) *Berz.*, Ak. H. Stockh., 1823. Telluric Bismuth. Tetradymite, Rhomboëdrische Wismuthglanz (fr. Schubkau) *Haid.*, Baumg. Zs., **9**, 129, 1831. Bismuth telluré, Tellure selenié bismuthifère *Fr.* Bornine *Beud.*, Tr.. **2**, 538, 1832. Bismuthotellurites pt. *Glocker*, Syn., 19, 1847. Tellurbismuth *Balch*, Am. J. Sc., **35**, 99, 1863.

Rhombohedral. Axis $\dot{c} = 1·5871$; $0001 \wedge 10\bar{1}1 = 61° 22\frac{5}{6}'$ Haidinger[1].

**Forms:** *c* (0001, *O*), *e* ($01\bar{1}2$, $-\frac{1}{2}$) as tw. pl., *f* ($20\bar{2}1$, 2), *μ* ($04\bar{4}1$, $-4$). **Angles:** $ce = 42° 30'$, $cf = 74° 44\frac{1}{2}'$, $c\mu = 82° 14'$, $rr' = 98° 58'$, $ff' = 113° 20'$, $\mu\mu' = 118° 12'$.

Twins: tw. pl. *e*; $c\underline{c} = *95°$; in fourlings. Crystals small and rarely distinct; acute rhombohedral, resembling hexagonal prisms; rhombohedral faces horizontally striated. Also in bladed forms and foliated to granular massive.

Cleavage: basal perfect. Laminæ flexible; not very sectile. H. = 1·5–2; soils paper. G. = 7·2–7·6. Luster metallic, splendent. Color pale steel-gray. Thermo-electrically positive in part, also sometimes negative[2].

**Comp., Var.**—Consists of bismuth and tellurium, with sometimes sulphur and a trace of selenium; the analyses for the most part afford the general formula $Bi_2(Te,S)_3$. Some authors regard the species as an isomorphous compound of bismuth and tellurium, and place it in the group of the rhombohedral metals.

**Var.**—1. *Free from sulphur.* $Bi_2Te_3$=Tellurium 48·1, bismuth 51·9; analyses 1–4. G.= 7·868 from Dahlonega, Jackson; 7·642, id., Balch.

2. *Sulphurous.* $2Bi_2Te_3.Bi_2S_3$ = Tellurium 36·4, sulphur 4·6, bismuth 59·0 = 100. This includes *tetradymite* Haid. from Schubkau, whose crystals yielded the above data; also other varieties analyzed by Genth. The name *Bornine*, after von Born, was given by Beudant in 1832, and Wehrle's analysis of the Schubkau ore was the only one cited.

**Anal.**—1, Genth, Am. J. Sc.. **19**, 16, 1855. 2. Id., ibid., **31**, 368, 1861. 3, Balch, ibid., **35**, 99, 1863. 4, Genth, ibid., **45**, 317, 1868. 5, Wehrle, Baumg. [a] S 4·40 after deducting 1·15 pyrite. [b] Deducting 15·6 % quartz, 1·8 $Fe_2O_3$.

**Pyr.**—In the open tube a white sublimate of tellurium dioxide, which B.B. fuses to colorless drops. On charcoal fuses, gives white fumes and entirely volatilizes; tinges the R.F. bluish green; coats the coal at first white ($TeO_2$), and finally orange-yellow ($Bi_2O_3$); some varieties give sulphurous and selenous odors.

**Obs.**—Occurs at Schubkau near Schemnitz; at Rezbanya; at Orawitza in the Banat; at Tellemark in Norway; at Bastnaes mine, near Riddarhyttan, Sweden.

In the United States, in Virginia, at the Whitehall gold mines, Spottsylvania Co., at Monroe mine, Stafford Co., and Tellurium mine, Fluvanna Co., with native gold; in North Carolina, Davidson Co., about 5 m. W. of Washington mine, in foliated scales and lamellar masses with gold, chalcopyrite, magnetite, epidote, limonite, etc.; and at the Phœnix mine, Cabarrus Co., and in gold washings of Burke and McDowell counties; in York district, So. Carolina; in Georgia, Lumpkin Co., 4 m. E. of Dahlonega, and also in Cherokee and Polk and Spaulding counties. In the gold washings of Highland, Montana, and at Uncle Sam's Lode. Rare at the Red Cloud mine, Colorado. In quartz with gold at the Montgomery mine, Hassayampa distr., Arizona also near Bradshaw City, Yavapai Co., in bladed crystals in quartz.

Named from τετράδυμος, *four-fold*, in allusion to the twin crystals.

**Ref.**—[1] Schubkau, Baumg. Zs., **9**, 129, 1831, cf. also Pogg., **21**, 595, 1831. [2] From Schubkau and Orawitza, positive; from Georgia, negative, Schrauf and Dana, Ber. Ak. Wien, **69** (1), 151, 1874, or Am. J. Sc., **8**, 262, 1874.

**32. JOSËITE.** Tellurure de Bismuth *Damour*, Ann. Ch. Phys., **13**, 372, 1845. Borning. Tellure bismuthifère du Brésil, *Dufr.* [not Bornine *Beud.*] Josëit *Kenng.*, Min., 121, 1853.

In laminated masses with perfect cleavage resembling tetradymite. Soft. Fragile. G. = 7·924–7·936. Luster metallic. Color grayish black, steel-gray.

**Comp.**—Bismuth and tellurium with some sulphur and selenium; the formula doubtful.

**Anal.**—1, 2, Damour, l. c. 3, Genth, Am. Phil. Soc. Philad., **23**, 31, 1885.

Rammelsberg obtained from an allied mineral, from Cumberland, England (Min. Ch., 5): Tellurium 6·73, sulphur 6·43, bismuth 84·33 = 97·49.

**Pyr.**—B.B. the Brazil ore acts nearly like tetradymite. In an open tube it gives off some sulphur, then white fumes of tellurium dioxide, and then affords a decided odor of selenium; and in the upper part of the tube a white coating with some brick-red over it, due to the selenium; and a yellowish residue below, due to the bismuth oxide.

**Obs.**—Found in granular limestone at San José, near Mariana, province of Minas Geraes, Brazil, and first brought to France by Mr. Claussen.

**33. WEHRLITE.** Argent molybdique *de Born*, Cat. de Raab., **2**, 419, 1790. Wasserbleisilber, Molybdän-silber, *Wern.*, Letztes Min. Syst., 18, 48, 1817. Molybdic silver. Analysis 2 corresponds to $AgBi_7Te_7$, and 3 to $Bi_8Te_5S$, or $Bi_3Te_2$, excluding $Ag_2S$.

**Pyr., etc.**—Like tetradymite.

**Obs.**—From Deutsch-Pilsen, in Hungary. First reported as an ore of silver and molybdenum. Named after Mining Commissioner Wehrle, of Hungary.

---

## 3. Molybdenite Group.

**34. MOLYBDENITE.** Not Molybdæna [ = product fr. partial reduct. and oxid of Galena] *Dioscor.*, *Plin.*, *Agric.* Blyertz, Molybdena pt. [rest graphite] *Wall.*, 131, 1747, *Linn.*, 1748, 1768. Sulphur ferro et stanno saturatum (fr. Bastnaes, etc.), Wasserbley pt., Molybdena pt., *Cronst.*, 139, 1758. Scheele Opuscula, **1**, 1778. Molybdæna (with discov. of metal) *Hielm*, Ak. H. Stockh., 1782, 1788–1793. Wasserblei *Wern.* Molybdänglanz *Germ.* Molybdena *Kirw.*, Min., 1796 (calls the metal Molybdenite). Sulphuret of Molybdena. Molybdénite *Brongn.*, **2**, 92, 1807, citing Kirwan as authority.

Hexagonal (?). Crystals hexagonal in form, tabular, or short prisms slightly tapering, *cx* = 75° Renfrew, resembling some mica. Prismatic planes horizontally striated; on the base sometimes striæ normal to the edges. Commonly foliated, massive or in scales; also fine granular.

Cleavage: basal eminent. Laminæ very flexible, but not elastic. Sectile. H. = 1–1·5. G. = 4·7–4·8; 4·708 Biellese, Cossa. Luster metallic. Color pure lead-gray; a bluish gray trace on paper, on porcelain slightly greenish. Opaque. Feel greasy.

**Comp.**—Molybdenum disulphide, $MoS_2$=Sulphur 40·0, molybdenum 60·0=100.

**Pyr., etc.**—In the open tube sulphurous fumes and a pale yellow crystalline sublimate of molybdenum trioxide ($MoO_3$). B.B. in the forceps infusible, imparts a yellowish-green color to the flame; on charcoal the pulverized mineral gives in O.F. a strong odor of sulphur, and coats the coal with crystals of molybdic oxide, which appear yellow while hot, and white on cooling; near the assay the coating is copper-red, and if the white coating be touched with an intermittent R.F., it assumes a beautiful azure-blue color. Decomposed by nitric acid, leaving a white or grayish residue (molybdic oxide).

**Obs.**—Generally occurs embedded in, or disseminated through, granite, gneiss, zircon-syenite, granular limestone, and other crystalline rocks. At Numedal in Sweden, Arendal, Selba, and Tellemarken in Norway, Nerchinsk in Eastern Siberia, and Auerbach in Saxony, it has been observed in hexagonal prisms. Found also at Altenberg and Ehrenfriedersdorf in Saxony; Schlackenwald and Zinnwald in Bohemia; Rathausberg in Austria; near Miask, Urals; Bastnaes, etc., Sweden; in Finland; Laurvik in Norway; Chessy in France; in Piedmont, Italy, at Traversella and Biellese; Peru; Brazil; Calbeck Fell, Carrock Fells, and near the source of the Caldew in Cumberland, associated with scheelite and apatite; several of the Cornish mines; in Scotland at East Tulloch; at Mount Coryby on Loch Creran, etc.

In *Maine*, at Blue Hill Bay and Camdage farm, in large crystallizations; also at Brunswick, Bowdoinham, and Sanford, but less interesting. In *Conn.*, at Haddam and the adjoining towns on the Connecticut river, in gneiss in crystals and large plates; also at Saybrook. In *Vermont*, at Newport, with crystals of white apatite. In *N. Hampshire*, at Westmoreland, four miles south of the north village meeting-house, in a vein of mica slate, abundant; at Llandaff in regular tabular crystals; at Franconia. In *Mass.*, at Shutesbury, east of Locke's pond; at Brimfield, with iolite. In *N. York*, two miles southeast of Warwick, in irregular plates associated with rutile, zircon, and pyrite. In *Penn.*, in Chester, on Chester Creek, near Reading; near Concord, Cabarrus Co., N. C., with pyrite in quartz. In *California*, at Excelsior gold mine, in Excelsior district and elsewhere. In *Canada*, at Balsam Lake, Terrace Cove, Lake Superior; north of Balsam Lake, on a small island in Big Turtle Lake, with scapolite, pyroxene, etc., in a vein of quartz intersecting crystalline limestone; at St. Jérôme, Quebec; at Seabeach Bay, near Black River, N. W. of L. Superior (48° 46′ N., 87° 17′ W.). In large crystals (1 to 2 inches across) in Renfrew county, Ontario, also in Aldfield township, Pontiac Co., Quebec.

Named from *μόλυβδος lead;* the name, first given to some substances containing lead, later included graphite and molybdenite, and even some compounds of antimony. The distinction between graphite and molybdenite was established by Scheele in 1778–79.

Artif.—Obtained crystallized by Schulten by melting together potassium carbonate, sulphur and molybdic oxide in a platinum crucible, G. = 5·06, G. För. Förh., **11**, 401, 1889.

## II. Sulphides, Selenides, Tellurides, Arsenides, Antimonides of the Metals.

### A. Basic Division.

### B. Monosulphides.

1. **Galena Group.** Isometric, holohedral.
2. **Chalcocite Group.** Orthorhombic.
3. **Sphalerite Group.** Isometric, tetrahedral.
4. **Cinnabar—Wurtzite—Millerite Group.** Hexagonal and rhombohedral.

### C. Intermediate Division.

Embraces Polydymite $Ni_4S_5$?, Melonite $Te_2S_3$, etc.; also Bornite $3Cu_2S.Fe_2S_3$, Linnæite $CoS.Co_2S_3$, Chalcopyrite $Cu_2S.Fe_2S_3$, etc.

### D. Disulphides, Diarsenides, etc.

1. **Pyrite Group.** Isometric, pyritohedral.
2. **Marcasite Group.** Orthorhombic.
3. **Sylvanite Group.**

## II. Sulphides, Selenides, Tellurides, etc., of the Metals.

### A. Basic Division. Dyscrasite Group.

| | | | | $\breve{a} : \bar{b} : \dot{c}$ |

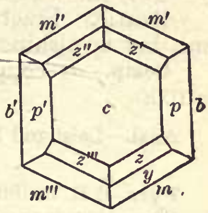
Twins: tw. pl. *m*, producing stellate forms, pseudo-hexagonal. Planes *c* striated ‖ *b*. Also massive, granular fine, or coarse and foliated.

1.



Andreasberg ?, Mlr.

Cleavage: *c*, *e* distinct, *m* imperfect. Fracture uneven. Sectile. H. = 3·5–4. G. = 9·44–9·85. Luster metallic. Color and streak silver-white, inclining to tin-white; somtimes tarnished yellow or blackish. Opaque.

**Comp.**—A silver antimonide, including $Ag_3Sb$ = Antimony 27·1, silver 72·9 = 100, and $Ag_6Sb$ = Antimony 15·7, silver 84·3 = 100, and perhaps other compounds.

Analyses (see 5th Ed., p. 35) vary widely, some conforming also to $Ag_2S$, $Ag_4(Sb,As)_3$, etc. Of the following, 1 and 2 agree with $Ag_3Sb$, 3 with $Ag_6Sb$. 1, Rg., Zs. G. Ges., **16**, 618, 1869. 2, 3, Petersen, Pogg., **137**, 377, 1869.

| | | | | Sb | Ag |
|---|---|---|---|---|---|
| 1. | Andreasberg | *cryst.* | G. = 9·73–9·77 | [27·56] | $\frac{3}{3}$ 72·44 = 100 |
| 2. | Wolfach | *cryst.* | G. = 9·611 | $\frac{3}{3}$ 27·20 | 71·52 = 98·72 |
| 3. | “ | *fine gran.* | G. = 10·027 | 15·81 | 83·85 = 99·66 |

Another fragment of the crystal analyzed by Rammelsberg (1) gave ($\frac{3}{3}$) Ag = 74·79, with G. = 9·851. A coarse granular form from Wolfach gave Petersen Sb 23 06, Ag 76·65, As *tr.* = 99·71, with G. = 9·960. Petersen calls the compound $Ag_3Sb$, *stibio-triargentite*, and $Ag_6Sb$, *stibio-hexargentite.*

Because of the similarity of form with chalcocite, etc., it has been urged that the true composition is $Ag_2Sb$, and that the variation is due to mechanical admixture, cf. Kenngott[2], Groth[3]. The analogy, however, of the copper arsenides and still more of artificial compounds (Cooke[4]) of zinc and antimony ($Zn_nSb$), which latter are near dyscrasite in form, speak against this.

Domeyko mentions silver ores with only 4 to 6 p. c. antimony. A silver-white mineral from Chañarcillo conforming approximately to the formula $Ag_4(Sb,As)_3$ has been called *chañarcillite.* (5th Ed., p. 36, 1868.)

**Pyr., etc.**—B.B. on charcoal fuses to a globule, coating the coal with white antimony trioxide and finally giving a globule of almost pure silver. Soluble in nitric acid, leaving antimony trioxide.

**Obs.**—Occurs in the Wenzelgang near Wolfach, Baden, where it is the chief silver ore (cf. Sandb., l. c.); it is crystalline, and in part fine granular, in part coarsely foliated; the latter forming masses in concentric layers, varying in structure and somewhat in composition; also at Wittichen in Suabia, and at Andreasberg in the Harz, commonly associated with other ores of silver, native arsenic, galena, etc.; also at Allemont, Isère in France, Casalla in Spain, and in Bolivia, S. A. Named from *δυσκρᾶσις, a bad alloy. Chanarcillite*, from Chañarcillo, is a silver-white ore for which Domeyko gives $Ag_2(As,Sb)_3$; 5th Ed., p. 36.

**Alt.**—Occurs at Wolfach, altered to pyrargyrite and native silver, cf. Sandberger, l. c.

**Ref.**—[1] Handb. Min., p. 57. 1847. Sandberger adds a pyramid probably 332, Unt. Erzg., **2**, 293, 1882. [2] Ber. Ak. Wien, **9**, 548, 1852. [3] Tab. Ueb. 20, 1882. [4] Am. J. Sc., **18**, 229, 1854; **20**, 222, 1855; cf. Rg., l. c., p. 623.

ARSENICAL SILVER. *Arseniksilber*, from Andreasberg, analyzed by Klaproth (Beitr., **1**. 183, 1795), and DuMenil (Schweig. J., **34**, 357, 1822), is regarded by Rammelsberg as a mixture perhaps of arsenopyrite, arsenical iron, and dyscrasite (Pogg., **77**, 262, 1849, and Min. Ch., 27, 1875). Called *pyritolamprite* by Adam, Tabl. Min., 39, 1869.

MACFARLANITE, HUNTILITE, ANIMIKITE. The ores from Silver Islet, Lake Superior, apparently contain a silver arsenide (*huntilite*) and perhaps also a silver antimonide (*animikite*), the latter related to or identical with dyscrasite. The name *macfarlanite* was given by Sibley to the complex ore consisting of a reddish-brown sectile metallic mineral mixed with silver and other species; this has been investigated by T. Macfarlane (Can. Nat., Feb. 1, 1870; Trans. Am. Inst. Mng. Eng., **8**, 236, 1880). The name huntilite, after Dr. T. Sterry Hunt, was given by Wurtz (Eng. Mng. J., **27**, 55, 1879) to the supposed silver arsenide, stated to be dark gray to black and massive, G. = 7·47; also slate-color and cleavable. Semi-malleable. G. = 6·27. The analyses were made on too impure material to allow of any decision as to the composition. $Ag_3As$ (= As 18·8, Ag 81·2 = 100) is sugested. Compare Koenig, Proc. Acad. Philad., 276, 1877. *Animikite*, Wurtz, l. c. p. 124, occurs on huntilite. Structure fine granular. Somewhat sectile. G. = 9·45. Color white to grayish white. The formula $Ag_9Sb$ is proposed, but very doubtful. Named from animiké, *thunder*, whence Thunder Bay. For analyses, etc., see further Min. 5th Ed., App. III, 71, 1882.

ARSENARGENTITE *J. B. Hannay*, Min. Mag., **1**, 149, 1877. Stated on the basis of a partial examination of a single specimen of doubtful source (Freiberg ?) to be $Ag_3As$, occurring in orthorhombic acicular crystals in native arsenic. G. = 8·825. Analysis: As [18·43], Ag 81·37 = 100. Needs confirmation.

### 36. HORSFORDITE. *A. Laist* and *T. H. Norton*, Am. Ch. J., **10**, 60, 1888.

Only known massive.

Brittle. Fracture uneven. H. = 4–5. G. = 8·812. Luster metallic; brilliant, but tarnishing easily. Color silver-white. Opaque.

**Comp.**—A copper antimonide, probably $Cu_6Sb$ = Antimony 24·0, copper 76·0 = 100.

**Anal.**—Laist and Norton:

$\frac{3}{3}$ Sb 26·86 Cu 73·37 = 100·23

**Pyr.**—B.B. fusibility 1·5. Reacts for antimony and copper.

**Obs.**—Occurs as a large deposit in Asia Minor not far from Mytilene.

Named for E. N. Horsford, formerly Rumford Professor of Chemistry in Harvard University.

**Artif.**—On octahedral crystals containing $Cu_6Sb$, see Brand, Zs. Kr., **17**, 264, 1889.

### 37. DOMEYKITE. Arsenikkupfer (fr. Copiapo) *Zinken*, Pogg., **41**, 659, 1837. Arseniure de cuivre *Domeyko*, Ann. Mines, **3**, 3, 1843; Cobre Blanco *id.*, Min., 138, 1845. Weisskupfer *Hausm.* Cuivre arsenical *Fr.* Arsenical Copper. Domeykite *Haid.*, Handb., 562, 1845. Condurrite *W. Phillips*, Phil. Mag., **2**, 286, 1827.

Reniform and botryoidal; also massive and disseminated.

Fracture uneven. H. = 3–3·5. G. = 7·2–7·75. Luster metallic, but dull on exposure. Color tin-white to steel-gray, with a yellowish to pinchbeck-brown, and afterward an iridescent tarnish.

**Comp.**—A copper arsenide, $Cu_3As$ = Arsenic 28·3, copper 71·7 = 100.

**Anal.**—1, Domeyko, after deducting 2·55 gangue, Ann. Mines, **3**, 6, 1843. 2. 3, Field, J. Ch. Soc., **10**, 289, 1857. 4, Frenzel, Jb. Min., 26, 1873. 5, Forbes, Q. J. G. Soc., **17**, 44, 1861. 6, Genth, Am. J. Sc., **33**, 193, 1862. 7, 8, Frenzel, l. c. 9, Winkler, Jb. Min., **2**, 255, 1882.

| 9. Zwickau | H. = 5. | G. = 6·84 | 26·45 | 65·08 | Fe 0·64, Ni 0·44, O 2·49, gangue 3 84 = 98 94 |

**Pyr., etc.**—In the open tube fuses and gives a white crystalline sublimate of arsenic trioxide. B.B. on charcoal arsenical fumes and a malleable metallic globule, which, on treatment with soda, gives a globule of pure copper. Not dissolved in hydrochloric acid, but soluble in nitric acid.

**Obs.**—From the Chilian mines of Algodones in Coquimbo, in Illapel, San Antonio in Copiapo, etc. Also from Zwickau, in Saxony, in porphyry.

In N. America, found on the Sheldon location, Portage Lake; and mixed with niccolite at Michipicoten Island, in L. Superior.

Domeykite is named for the Chilian mineralogist, Ignacio Domeyko.

*Condurrite* is a mixture, the result of alteration (of tennantite?, Rg.). It is black and soft, soiling the fingers. It has been investigated by Rammelsberg (Pogg., **71**, 305, 1847) and Winkler (B. H. Ztg., **18**, 383, 1859), also earlier by Faraday, Blyth and Kobell. Cf. 5th Ed., p. 37. From the Condurrow mine, near Helstone, and Wheal Druid mine at Carnbrae, near Redruth, Cornwall.

ORILEYITE *D. Waldie*, Proc. Asiat. Soc., Bengal, p. 279, September, 1870.

Massive. H. = 5·5. G. = 7·343–7·428. Color steel-gray on fresh fracture with purplish tint. Luster metallic. Streak dark gray. Analysis, D. Waldie: As 38·45, Sb 0·54, Cu 12·13, Fe 42·12, X 6·19, Insol. 0·12 = 99·55. X = oxidized matters soluble in dilute hydrochloric acid = CuO 1·21, FeO 1·97, PbO 1·89, $As_2O_3$ 1·12 = 6·19. Soluble in nitric acid. From Burma, but exact locality not known. Named after Mr. O'Riley, Deputy Commissioner of Martaban, Burma.

The analysis corresponds approximately, as shown by Mallet (Min. India, 14, 1887), to $(Cu_2,Fe)_3$ $(As,Sb)_2$, which if confirmed makes the mineral allied to domeykite.

**38. ALGODONITE.** *F. Field,* J. Ch. Soc., **10**, 289, 1857.

In incrustations minutely crystalline. Commonly massive and distinctly granular.

Fracture subconchoidal, affording a granular surface. H. = 4. G. = 7·62, Chili, Genth. Luster metallic and bright, but becoming dull on exposure. Color steel-gray to silver-white, the latter on a polished surface. Opaque.

**Comp.**—$Cu_6As$ = Arsenic 16·5, Copper 83·5 = 100.

**Anal.**—1, F. Field, l. c. 2–4, Genth, Am. J. Sc., **33**, 192, 1862.

| | | | | As | Cu | Ag | |
|---|---|---|---|---|---|---|---|
| 1. | Chili | | $\frac{5}{5}$ | 16·23 | 83·30 | 0·31 | = 99·84 |
| 2. | " | G. = 7·603 | $\frac{8}{8}$ | 16·95 | 82·42 | *tr.* | = 99·37 |
| 3. | L. Superior | | | 15·30 | 84·22 | 0·32 | = 99·84 |
| 4. | " | | | 16·72 | 82·35 | 0·30 | = 99·37 |

In analysis 3, a little whitneyite was mixed with the ore, and hence the higher percentage of copper (Genth).

**Pyr.**—The same as with domeykite, but less fusible.

**Obs.**—In Chili, at the silver mine of Algodones, near Coquimbo, in the Cerro de los Seguas, Department of Rancagua; in the United States, in the Lake Superior region. A transported mass of mixed whitneyite and algodonite, weighing 95–100 lbs., was found on St. Louis R. The color is grayer, and the texture more granular and less malleable, than in whitneyite.

**39. WHITNEYITE.** *Genth,* Am. J. Sc., **27**, 400, 1859, **33**, 191, 1862. Darwinite *D. Forbes,* Phil. Mag., **20**, 423, 1860.

Massive. Crystalline; very fine granular.

Malleable. H. = 3·5. G. = 8·4–8·6. Luster dull and sub-metallic on surface of fresh fracture, but strong metallic where scratched or rubbed, soon tarnishing. Color pale reddish to grayish white, pale reddish white on a rubbed surface; becoming yellowish bronze, brown, and brownish black on exposure. Sometimes iridescent. Opaque.

**Comp.**—$Cu_9As$ = Arsenic 11·6, copper 88·4 = 100.

**Anal.**—1–3, F. A. Genth, l. c. 4, Id., Am. J. Sc. **45**, 306, 1868. 5, D. Forbes, l. c.

| | | | | As | Cu | Ag & insol. | |
|---|---|---|---|---|---|---|---|
| 1. | Michigan | G. = 8·408 | $\frac{2}{2}$ | 11·61 | 88·13 | 0·40 | = 100·14 |
| 2. | " | | | 12·28 | 87·48 | 0·04 | = 99·80 |
| 3. | " | G. = 8·47 | | 12·28 | 87·37 | 0·03 | = 99·68 |
| 4. | Sonora | | | 11·46 | 88·54 | *tr.* | = 100 |
| 5. | Chili | G. = 8·64 | $\frac{4}{4}$ | 11·58 | 88·14 | 0·28 | = 100 |

**Pyr.**—Less fusible than algodonite; otherwise as in domeykite.

**Obs.**—In Houghton Co., Michigan, coated with red copper. A loose mass, weighing about 15 lbs., and consisting partly of algodonite, was found on the Pewabic location, 1 m. from Hancock village, Portage Lake; also found in place on the Sheldon location, near Houghton, Mich.; stated to occur at the Albion location, about a mile from the Cliff mine, in a vein 4 inches wide; also at the Minnesota mine; also in Sonora (Genth), near La Laguna, a ranch on the road to Libertad, Gulf of California, 35 m. fr. Saric; reported also from the Lape and Fuller mine, Austin, Nevada. Darwinite (anal. 5) is stated to occur near Potrero Grande, southeast of Copiapo, Chili.

Named after Prof. J. D. Whitney of Cambridge, Mass., formerly State Geologist of California.

A mineral related to whitneyite, from Fortuna di Paposa, Chili, gave Bertrand 7·5 p. c. As, Ann. Mines, **1**, 413, 1872.

**40. CHILENITE.** Aleacion de plata con bismuto *Domeyko,* Min., 187, 1845. Plata bismutal *Id.*, ib., 185, 1860. Chilenite *Dana,* Min., 1868, 36.

Amorphous; granular.

Soft. Silver-white, but tarnishing easily to yellowish.

**Comp.**—Contains bismuth and silver, perhaps $Ag_6Bi$ = Bismuth 13·8, silver 86·2. Domeyko obtained: Bi 10·1, Ag 60·1, Cu 6·8, As 2·8, gangue 19·0, corresponding to Bi 14·4, silver 85·6. Also (Ann. Mines, **5**, 456, 1864) Bi 15·3, Ag 84·7. For the last the material was separated from a mass containing 8 to 10 p. c. of it disseminated in small points.

**Obs.**—From the mine of San Antonio, Potrero Grande, in Copiapo.

For the bismuth silver of Schapbach, see p. 122.

**41. Stützite.** Tellursilberblende *Schrauf*, Zs. Kr., **2**, 245, 1878.

Hexagonal, or pseudo-hexagonal. If hexagonal, axis $\acute{c}$ = 1·2530; 0001 ∧ 10$\bar{1}$1 = 55° 21′.

**Forms:** *c* (0001, *O*); *a* (11$\bar{2}$0, *i*-2), *m* (10$\bar{1}$0, *I*), *h* (21$\bar{3}$0, *i*-$\frac{3}{2}$), *l* (41$\bar{3}$0, *i*-$\frac{4}{3}$), *d* (10$\bar{1}$4, $\frac{1}{4}$), *f* (10$\bar{1}$2, $\frac{1}{2}$), *g* (10$\bar{1}$1, 1), *s* (30$\bar{3}$2, $\frac{3}{2}$); *μ* (11$\bar{2}$6, $\frac{1}{3}$-2), *z* (11$\bar{2}$4, $\frac{1}{2}$-2), *y* (11$\bar{2}$2, 1-2), *x* (11$\bar{2}$1, 2-2); *i* (21$\bar{3}$2, $\frac{3}{2}$-$\frac{3}{2}$), *o* (31$\bar{4}$2, 2-$\frac{4}{3}$). Angles: *cf* = 35° 53′, *cs* = 65° 16′, *cz* = 32° 4′, *cy* = 51° 24½′, *cx* = 68° 15′.

Schrauf prefers a monoclinic parameter, viz, $\grave{a} : \bar{b} : \acute{c}$ = 1·73205 : 1 : 1·25829, *β* = 89° 33′. A similarity in form to dyscrasite (as also to chalcocite) is apparent, and it may be orthorhombic and pseudo-hexagonal like them.

Crystals highly modified. Faces mostly brilliant; *m* horizontally striated.

Fracture uneven to subconchoidal. Luster metallic. Color lead-gray, with reddish tinge. Streak blackish lead-gray.

**Comp.**—A silver telluride, perhaps $Ag_4Te$ = Tellurium 22·5, silver 77·5 = 100. The silver percentage determined approximately with the blowpipe in two trials 72 p. c. and 77 p. c.

**Pyr.**—Easily fusible to a dark bead, from which a silver globule is obtained by reduction with soda; yields tellurium dioxide in the open tube.

**Obs.**—Identified on a single specimen in the collection of the Vienna University; locality probably Nagyág, Transylvania. Associated with gold and hessite on quartz. Named after Stütz, who, in 1803, described a tellurium mineral from Nagyág, which is regarded by Schrauf as probably identical with this.

---

## B. Monosulphides, Selenides, Tellurides, etc.

### 1. Galena Group. RS. Isometric, holohedral.

Monosulphides, etc., of silver, copper, lead and mercury.

**42. ARGENTITE.** Argentum rude plumbei coloris et Galenæ simile, cultro diffinditur, dentibus compressum dilatatur, *Agric.*, 438, 1529; *Germ.* Glaserz, *Agric.*, Interpr., 463, 1546; *Henckel*, Min., 1734 (proving it a sulphur compound). Silfverglas, Minera argenti vitrea, Argentum sulphure mineralisatum. *Wall.*, 308, 1746; *Sage*, Ann. Ch., 2, 250, 1776 (with earliest anal.). Glanzerz, Silberglas, Silberglanz, Schwefelsilber, Weichgewächs, *Germ.* Vitreous Silver, Sulphuret of Silver, Silver Glance. Argent sulfuré *Fr.* Argyrose *Beud.*, Tr., 2, 392, 1832. Argentit *Haid.*, Handb., 565, 1845. Argyrit *Glock.*, Syn., 23, 1847. Argirose *Ital.* Plata sulfurea *Span.* Petlanque nero *Span.*, *S. A.*

Isometric. Observed planes [1]:

| | | | |
|---|---|---|---|
| *a* (100, *i*-*i*) | *f* (310, *i*-3)[2] | *p* (221, 2) | *z* (322, $\frac{3}{2}$-$\frac{3}{2}$) |
| *d* (110, *i*) | *e* (210, *i*-2) | *m* (311, 3-3) | *x* (433, $\frac{4}{3}$-$\frac{4}{3}$)[2] |
| *o* (111, 1) | *g* (320, *i*-$\frac{3}{2}$) | *n* (211, 2-2) | *σ* (533, $\frac{5}{3}$-$\frac{5}{3}$) |

Penetration-twins: tw. plane *o*. Forms *a*, *d*, *o* most common; crystals often distorted, frequently grouped in parallel position making reticulated, arborescent forms; also filiform. Massive, embedded or as a coating.

Cleavage: *a*, *d* in traces. Fracture small subconchoidal. Perfectly sectile. H. = 2–2·5. G. = 7·20–7·36; 7·296 Freiberg, Dbr. Luster metallic. Color and streak blackish lead-gray; streak shining. Opaque.

**Comp.**—Silver sulphide, $Ag_2S$ = Sulphur 12·9, silver 87·1 = 100.

**Pyr., etc.**—In the open tube gives off sulphurous fumes. B.B. on charcoal fuses with intumescence in O. F., emitting sulphurous fumes, and yielding a globule of silver.

**Obs.**—Found at Freiberg, Annaberg, Joachimsthal of the Erzgebirge; at Schemnitz and Kremnitz in Hungary; in Norway near Kongsberg; in the Altai at the Zmeinogorsk mine; in the Urals at the Blagodatsk mine; in Cornwall; in Bolivia; Peru; Chili; Mexico at Guanajuato, Zacatecas, Catorce, San Pedro del Potosi, etc.

Occurs in Nevada, at the Comstock lode, at different mines, along with stephanite, native gold, etc.; in the vein at Gold Hill; common in the ores of Reese river; probably the chief ore of silver in the Cortez district; in the Kearsarge district, Silver-Sprout vein. At the Silver King mine, in Arizona. At mines near Port Arthur on north shore of Lake Superior. Occurs with native silver and copper in northern Michigan.

Acanthite (p. 58) may be only argentite in distorted crystals with orthorhombic symmetry, Krenner.

**Alt.**—Native silver, at Joachimsthal. Also a mixture called silver-black (Silberschwärze *Germ.*).

**Ref.**—[1] Cf. Schrauf, Ber. Ak. Wien, **63** (1), 165, 1871, and Atlas, Taf. xxiii. [2] Groth, Min. Samml., Strassburg, 50, 1878.

JALPAITE *Breithaupt*, B. H. Ztg., **17**, 85, 1858.—A cupriferous argentite from Jalpa, Mexico. Isometric in cleavage, and malleable like ordinary argentite; color blackish lead-gray; G. = 6·877–6·890. Composition according to T. Richter (l.c.): S 14·36, Ag 71·51, Cu 13·12, Fe 0·79 = 99·78, affording the formula $3Ag_2S.Cu_2S$.

Bertrand obtained for a brittle mineral from Tres Puntas, Chili, associated with argentite: S 14·02, Ag 71·63, Cu 13·06, Fe 0 57 = 99·28; Ann. Mines, **1**, 413, 1872. Cf. stromeyerite.

**43. HESSITE.** Tellursilber *G. Rose*, Pogg., **18**, 64, 1830. Savodinskite *Huot*, Min., **1**, 187, 1841. Telluric Silver. Hessit *Fröbel*, Grundz. Syst. Kryst., 49, 1843. Tellursilberglanz *Germ.*

Isometric. Observed forms[1]:

*a* (100, *i-i*); *d* (110, *i*); *o* (111, 1); *f* (310, *i*-3), *e* (210, *i*-2)[2]; *p* (221, 2), *q* (331, 3)[3]; *m* (311, 3-3)[3], *n* (211, 2-2)[2], *z* (322, $\frac{3}{2}$-$\frac{3}{2}$)[3].

Crystals sometimes highly modified, and often much distorted. Also massive, compact or fine-grained; rarely coarse granular.

Cleavage indistinct Fracture even. Somewhat sectile. H. = 2·5–3. G. = 8·31–8·45; 8·89. Luster metallic. Color between lead-gray and steel-gray.

**Comp.**—Silver telluride, $Ag_2Te$ = Tellurium 36·7, silver 63·3 = 100. Gold is often present, replacing part of the silver; it thus graduates toward petzite.

**Anal.**—1, Rose, l. c. 2, Petz, Pogg., **57**, 467, 1842. 3, Becke, Min. Mitth., **3**, 301, 1880. 4, 5, Genth, Am. J. Sc., **45**, 311, 1868. 6–8, Id., Am. Phil. Soc., **14**, 226, 1874. 9, Raht (blowpipe), quoted by Genth, ib., **17**, 115, 1877.

| 9. Kearsage Mine, Utah | | *undet.* | 58·79 | 0·10 | |

**Pyr.**—In the open tube a faint white sublimate of tellurium dioxide which B.B. fuses to colorless globules. On charcoal fuses to a black globule; this treated in R.F. presents on cooling white dendritic points of silver on its surface; with soda gives a globule of silver.

**Obs.**—Occurs in the Savodinski mine, about 10 versts from the rich silver mine of Zyrianovski, in the Altai, in Siberia, in a talcose rock, with pyrite, black sphalerite, and chalcopyrite. Specimens in the museum of Barnaul, on the Ob, are a cubic foot in size. Also found at Nagyág in Transylvania, and in highly modified crystals at the Jacob and Anna mines, Botés Mt., between Zalathna and Verespatak; also at Rezbanya, Hungary. In Chili, near Arqueros, Coquimbo. A silver telluride (hessite or petzite) has been noted at the Maria mine, Karangahake, New Zealand.

In the U. S., at the Stanislaus mine. Calaveras Co., Cal. Sparingly at the Red Cloud mine, Boulder county, Colorado; also at the Kearsarge mine, Dry Cañon, Utah.

Named after G. H Hess of St. Petersburg (1802–1850).

**Ref.**—[1] Schrauf, Rezbanya, Zs. Kr., **2**, 242, 1878; also [2] Knr., Botés, Transylvania. ibid., **4**, 542, 1880. [3] Becke (l. c.) concludes from irregularity in angles, earlier noted by Schrauf, that the crystals are triclinic. Kenngott referred crystals to the orthorhombic system, Ber. Ak. Wien, **9**, 20, 1853; Hess to the rhombohedral, Pogg., **28**, 407, 1833; cf. Schrauf, l. c.

**44. PETZITE.** Tellursilber Petz, Pogg. **57**, 470, 1842. Tellurgoldsilber *Hausm.* Handb., **2**, 51, 1847. Petzit *Haid.*, Handb., 556, 1845.

Massive; fine granular to compact.

Fracture subconchoidal. Slightly sectile to brittle. H. = 2·5–3. G. = 8·7–9·02. Luster metallic. Color steel- or iron-gray to iron-black; often tarnishing.

**Comp.**—A telluride of silver and gold $(Ag,Au)_2Te$, if Ag : Au = 3 : 1 = Tellurium 32·5, silver 42·0, gold 25·5 = 100.

**Anal.**—1, Petz., l. c. 2, 3, 4, Genth, Am. J. Sc., **45**, 310, 1868. 5, 6, Id., Am. Phil. Soc. **14**, 226, 1874.

**Pyr.**—Like hessite, but yields a globule containing both gold and silver.

**Obs.**—Occurs at Nagyág, Transylvania. In the U. S. at the Red Cloud mine, Boulder Co., Colorado; at the Stanislaus and Golden Rule mines, California.

Named after W. Petz.

Groth suggests that petzite may be orthorhombic and hence belong to the chalcocite group.

**45. GALENA**, or GALENITE. Galena *Plin.*, **33**, 31 [not Galena or Molybdæna (= litharge-like product from the ore), *Plin.*, **34**, 47, 53]. *y* (521, 5-$\frac{5}{2}$)[4]
*s* (321, 3-$\frac{3}{2}$)

Twins: tw. pl. *o*, both contact- and penetration-twins, sometimes repeated; twin crystals often tabular ∥ *o*. Also tw. pl. *ρ* (441)[8], *m* (311)[9], and *q* (331)[10] as seen in polysynthetic tw. lamellæ often giving rise to striations on a cleavage surface; in some cases these are secondary and due to pressure.[12] Commonly in cubes, or cubo-octahedrons, less often habit octahedral. Also in skeleton crystals, reticulated, tabular. Massive cleavable, coarse or fine granular, to impalpable; occasionally fibrous or plumose.

Cleavage: cubic, highly perfect; less often octahedral. Fracture flat subconchoidal or even. H. = 2·5–2·75. G. = 7·4–7·6. Luster metallic. Color and streak pure lead-gray. Opaque. Thermo-electrically" positive, Sardinia, G. = 7·428; also negative, Přibram, G. = 7·575.

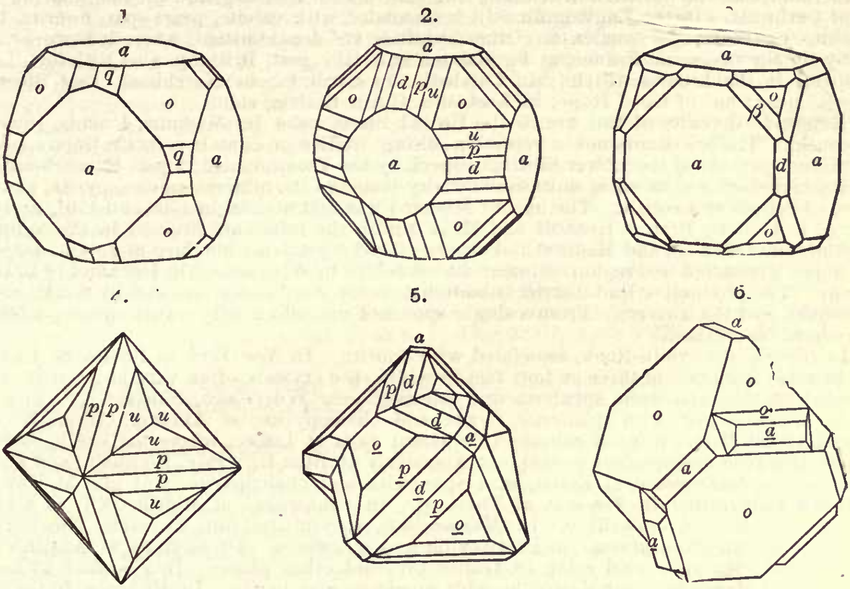

Fig. 1, Freiberg. 2, Neudorf, Schrauf. 3, Rossie, J. D. D. 4, Oberlahr, Schrauf.
5, Neudorf, Sbk. 6, Freiberg, Sbk.

**Comp., Var.**—Lead sulphide, PbS = Sulphur 13·4, lead 86·6 = 100. Contains silver, and occasionally selenium, zinc, cadmium, antimony, bismuth, copper, as sulphides; besides, also, sometimes native silver and gold; and even platinum has been reported as occurring in a galena from the Dept. of Charente, France.

**Var.**—1. *Ordinary.* (*a*) Crystallized; (*b*) somewhat fibrous and plumose; (*c*) cleavable, granular coarse or fine; (*d*) cryptocrystalline.

The variety with octahedral cleavage is rare; the following cases have been noted: Lancaster Co., Penn., with G. = 7·63; Habach, Salzburg, G. = 7·50, $Bi_2S_3$ = 1·97; Glacier Leschant, Mont Blanc, with G. = 7·67 and $Bi_2S_3$ = 1 p. c.; Nordmark, Sweden, G. = 7·508, $Bi_2S_3$ 0·91. In these cases the usual cubic cleavage is obtained readily after heating to 200° or 300° (then G. = 7·475 Nordmark), cf. Cooke, Torrey. Am. J. Sc., **35**, 126, 1863; Zeph, Zs. Kr., **1**, 155, 1877; Brun, Bull. Soc. Min., **4**, 260, 1881; H. Sj., G. För. Förh,, **7**, 124, 1884. It has been suggested that the peculiarity of cleavage may be connected with the bismuth usually present.

2. *Argentiferous.* All galena is more or less argentiferous, and no external characters serve to distinguish the kinds that are much so from those that are not. The silver is detected by cupellation, and may amount from a few thousandths of one per cent to one per cent or more; when mined for silver it ranks as a *silver ore.*

3. Containing arsenic, or antimony, or a compound of these metals, as impurity. Here belong the following, which appear to be merely impure galena. *Bleischweif* from Clausthal with 2·22 Zn, 0·34 Fe, 0·22 Sb (Rg.); *targionite* from Argentiera, Tuscany, with 5·77 Sb, 1·77 Fe, 1·11 Cu, 1·33 Zn, 0·72 Ag (Bechi); and *steinmannite* from Přibram, with both arsenic and antimony. *Supersulphuretted lead* of Johnston and others (or *Johnstonite*) contains an excess of sulphur owing to a decomposition of a portion of the mass, setting part of the sulphur free.

**Pyr.**—In the open tube gives sulphurous fumes. B.B. on charcoal fuses, emits sulphurous fumes, coats the coal yellow near the assay (PbO) and white with a bluish border at a distance ($PbSO_3$), and yields a globule of metallic lead. Decomposed by strong nitric acid with the separation of some sulphur and the formation of lead sulphate.

**Obs.**—One of the most widely distributed of the metallic sulphides. Occurs in beds and veins, both in crystalline and uncrystalline rocks. It is often associated with pyrite, marcasite, sphalerite, chalcopyrite, arsenopyrite, etc., in a gangue of quartz, calcite, barite or fluor, etc.; also with cerussite, anglesite, and other salts of lead, which are frequent results of its alteration It is also common with gold, and in veins of silver ores.

At Freiberg in Saxony it occupies veins in gneiss; in Spain, in granite at Linares [illegible] in Catalonia, Grenada, and elsewhere; at Clausthal and Neudorf in the Harz, and at Přibram in Bohemia, it forms veins in clay slate; in Styria it occurs in the same kind of rock in beds; at Sala in Sweden it forms veins in granular limestone; through the graywacke of Leadhills and the killas of Cornwall, in veins; filling cavities in the Subcarboniferous limestone in Derbyshire, Cumberland, and the northern districts of England; also in Bleiberg, and the neighboring localities of Carinthia. In the English mines it is associated with calcite, pearl spar, fluorite, barite, witherite, calamine, and sphalerite. Other localities are Joachimsthal, where it is worked principally for the silver; in France, at Poullaouen and Huelgoet, Brittany, also Villefort, Lozère; in Spain, in the Linares district; in Catalonia; in Sardinia; in Nerchinsk, East Siberia; in Algeria; near Cape of Good Hope; in Australia; Chili; Bolivia, etc.

Extensive deposits of this ore in the United States exist in Missouri, Illinois, Iowa, and Wisconsin. The ore occurs not in veins but filling cavities or chambers in stratified limestone, of different periods of the Lower Silurian, especially the Trenton, also in part Subcarboniferous. It is associated with sphalerite, smithsonite ("dry-bone" of the miners), calcite, pyrite, and often an ore of copper and cobalt. The lead of Missouri was first noticed in 1700 and 1701, and rediscovered in 1720 by Francis Renault and M. la Motte; the mines are situated in the counties of Washington, Jefferson, and Madison and others. Good crystals are obtained at Joplin, Jasper Co. The upper Mississippi lead region embraces 62 townships in Wisconsin, 8 in Iowa and 10 in Illinois (Owen). The productive lead district is bounded on the west, north, and east by the Mississippi, Wisconsin, and Rock rivers. From a single spot, not exceeding fifty yards square, 1,500 tons of ore have been raised.

In *Illinois*, at Cave-in-Rock, associated with fluorite. In *New York*, at Rossie, St. Lawrence Co., in veins from one to three or four feet in width, the crystals often very large, with calcite, and chalcopyrite, and some sphalerite and celestite; near Wurtzboro, Sullivan Co., in a large vein in millstone grit, with sphalerite, pyrite, and chalcopyrite; at Ancram, Columbia Co.; in Ulster Co. In *Maine*, veins of considerable extent exist at Lubec, where the ore is associated with chalcopyrite and sphalerite; also less extensively at Blue Hill Bay, Bingham, and Parsonsville. In *New Hampshire*, at Eaton, with sphalerite and chalcopyrite; and also at Haverhill, Bath, and Tamworth. In *Vermont*, at Thetford. In *Connecticut*, at Middletown, in a vein in argillyte, massive and crystalline. In *Massachusetts*, at Southampton, Leverett, Newburyport, and Sterling. In *Pennsylvania*, at Phenixville and elsewhere. In *Virginia*, at Austin's mines in Wythe Co., Walton's gold mine in Louisa Co., and other places. In *Tennessee*, at Brown's Creek, and at Haysboro, near Nashville, with sphalerite and barite. In *Michigan*, in the region of Chocolate river and elsewhere, and Lake Superior copper district; on the N. shore of L. Superior, in Neebing on Thunder Bay, and around Black Bay.

In *California*, at many of the gold mines. In *Nevada*, abundant in the Eureka district, and at Steamboat Springs, Washoe Co. In *Arizona*, in the Castle Dome, Eureka, and other districts. In *Colorado*, at Leadville there are productive mines of argentiferous galena, also at Georgetown and in the San Juan district and elsewhere. Mined for silver in the Cœur d'Alene region in Idaho; also at various points in Montana.

The name galena is from the Latin *galena* (γαλήνη), a name given to lead ore or the dros from melted lead. In Spanish South America, galena is called *carne de vaca*, when showin broad crystalline surfaces; when presenting small surfaces, *soroche;* when **granular**, *acerilla;* of a fibrous structure, *frangilla*. Galena, coarse-grained and in lumps large enough to be use to glaze potters' ware, is sometimes called *potters' ore;* also called Glasurerz *Germ.*, alquifoux *Fr.*, archifoglio *Ital.*

**Alt.**—Minium, anglesite, cerussite, pyromorphite, wulfenite, tetrahedrite, chalcocite, rhodochrosite, quartz, limonite, pyrite, pistomesite (pistopyrite Breith.), calamine, occur as pseudomorphs after galena, partly from alteration, and partly through removal and substitution. A change to the carbonate (cerussite), with the setting free of sulphur which is sometimes found in crystals, is the most common.

Galena also occurs as pseudomorph after pyromorphite (Blaubleierz *Germ.*) at Bernkastel on the Mosel and elsewhere. Breithaupt called it *plumbeine*, or one species of his *Sexangulites*, regarding this lead sulphide as crystallized in hexagonal prisms, and not a pseudomorph.

*Fournetite* of Ch. Mène (C. R., **51**, 463, 1860), supposed to be near tetrahedrite, is pronounced by Fournet (C. R., **54**, 1096, 1862) a mixture of galena with copper ore.

**Artif.**—Galena is sometimes a furnace product. It has been made in crystals by heating oxide or silicate of lead with vapor of sulphur (Wurtz); also by suspending lead sulphate in a bag in water saturated with carbon dioxide, and in which putrid fermentation is kept up (as by an oyster in the water), there resulting an incrustation of galena upon the shells (Gages, Brit. Assoc., 206, 1863). Cf. Doelter, Zs. Kr., **11**, 33, 41, 1885, also Fouqué-Lévy, Synth. Min., 308, 1882, and Weinschenk, Zs. Kr., **17**, 497, 1890. Occurs as a recent formation on coins at Bourbonne-les-Bains, Daubrée. It has been deposited as a specular film by means of a thiocarbamide (Reynolds).

[12] On percussion-figures, see Weiss, Zs. G. Ges., **29**, 209, 1877; on gliding-planes, etc., Bauer, Jb. Min., **1**, 138, 1882, **1**, 191, 1886; on etching figures, Becke, Min. Mitth., **6**, 237, 1884, **9**, 16, 1887.

HUASCOLITE *Dana*, Min., 42, 1868. Galena blendosa *Domeyko*, Min., 168, 1860. Sulphide of lead and zinc *D. Forbes*, Phil. Mag., **25**, 110, 1863. The characters are mostly those of galena. It has a granular or saccharoidal structure, a lead-gray color rather paler than ordinary galena, but little luster, and is apparently homogeneous and without any mixture of sphalerite. Domeyko obtained (l. c.) S 19·2, Pb 48·6, Zn 25·6, gangue 3·1; which corresponds nearly to PbS. 1½ ZnS. It comes from Ingahuas, in the province of Huasco, where it forms large aggregated masses or nodules in the lower part of the vein.

A massive mineral having a bluish-gray color is referred to huascolite by *Raimondi* (Min. Pérou, p. 202, 1878). He obtained after deducting 14·50 p. c. gangue: S 27·76, Pb 26·86, Zn 44·50, Fe 0·88 = 100; from the Poderosa mine, Province Dos de Mayo, Peru, where it is called *chumbe blanco* or *pavonado blanco*. *Domeyko* describes a mineral from Morochocha, Peru, corresponding in composition to PbS.(Zn,Fe)S, with Zn = 16·59 p. c.; another from Corocoro, Bolivia, afforded 5 p. c. ZnS (6th App. Min. Chili, p. 17, 1878).

Another similar mineral occurs in the East Ovoca district, county of Wicklow, Ireland, and also in Anglesey; it has been called *kilmacooite*, after the district called Kilmacoo, and is locally known as *bluestone*. It is hard, with fine-grained saccharoidal structure. G. = 4·736. Color steel-gray. According to C. R. C. Tichborne, who characterizes it as an "argentiferous galenitic blende," it consists of ZnS 37·68 p. c., PbS 29·07, $Ag_2S$ 0·275. Sc. Proc. R. Dublin Soc., **4**, 300, 1885.

CUPROPLUMBITE *Breith.*, Pogg., **61**, 672, 1844. Kupferbleiglanz *Germ.* Galena cobriza *Domeyko*, 168, 1860. Alisonite *Field*, Am. J. Sc., **27**, 387, 1859. Plumbocuprite *Adam*, Tabl. Min., 56, 1869.

Cuproplumbite is a massive mineral varying in structure, color, and luster from those of galena to nearly those of chalcocite and covellite; the color a little darker, and passing to iron-gray and indigo-blue; the luster generally feeble and sometimes almost wanting. The specimens contain disseminated ores of copper, and come from a mine in Catemo (Aconcagua), Chili. Plattner's analysis (1 below) corresponds to $Cu_2S.2PbS$.

Alisonite (named after R. E. Alison) is also massive with a deep indigo-blue color quickly tarnishing; the analysis (2) corresponds to $3Cu_2S.PbS$; from Mina Grande, near Coquimbo, Chili. Ulrich mentions a similar mineral from Victoria, Australia.

Analysis 4, corresponding to $2Cu_2S.PbS$, is of a massive, dark bluish gray mineral from an abandoned mine at St. Maurice in the Val Godemas, Hautes Alpes; it is associated with chalcopyrite, sphalerite, galena, and an argentiferous tetrahedrite.

Anal.—1, Plattner, Pogg., **61**, 671, 1844. 2, Field, l. c. 3, Id., J. Ch. Soc., **14**, 160, 1860. 4. Lodin, Bull. Soc. Min., **6**, 178, 1883.

| | | | S | Pb | Cu | Ag | |
|---|---|---|---|---|---|---|---|
| 1. | *Cuproplumbite* | G. = 6·41–6·43 | [15·1 ] | 64·9 | 19·5 | 0·5 | = 100 |
| 2. | *Alisonite* | G. = 6·10 | 17·00 | 28·25 | 53·63 | — | = 98·88 |
| 3. | " | | 17·69 | 28·81 | 53·28 | — | = 99·78 |
| 4. | Val Godemas | G. = 6·17 | 17·54 | 35·87 | 44·52 | 0·11 | Sb 0·62, As *tr.*, Fe 0·79, $SiO_2$ 0·25 = 99·70 |

Whether all the above minerals represent definite homogeneous compounds, or only ill-defined alteration products, is uncertain, and if so it is not clear whether they should be classed with isometric galena or with orthorhombic chalcocite. It may be noted that an artificial compound, crystallizing in the isometric system, consists of $Cu_2S$,PbS and $Fe_2S$ according to Brand, Zs. Kr., **17**, 264, 1889.

**46. ALTAITE.** Tellurblei *G. Rose*, Pogg., **18**, 68, 1830. Elasmose *Huot.*, Min., **1**, 1841; *O. d'Halloy*, Introd. à la Geol., 1833 (not of Beud. Tr., 1832), etc. Altait *Haid.*, Handb., 556, 1845. Plomo telural *Domeyko*.

Isometric. Usually massive; rarely in cubes.

Cleavage: cubic. Fracture subconchoidal. Sectile. H. = 3. G. = 8·16, G. Rose. Luster metallic. Color tin-white, with a yellowish tinge tarnishing to bronze-yellow. Opaque.

**Comp.**—Lead telluride, PbTe = Tellurium 37·7, lead 62·3 = 100.

**Anal.**—1, 2, Genth; 1, Am. J. Sc., **45**, 312, 1868; 2, Am. Phil. Soc. Philad., **14**, 225, 1874.

| | Te | Pb | |
|---|---|---|---|
| 1. Stanislaus Mine, Cal. | 37·31 | 60·71 | Ag 1·17, Au 0·26 = 99·45 |
| 2. Red Cloud Mine, Col. | 38·48 | 61·52 | = 100 |

**Pyr.**—In the open tube fuses, gives fumes of tellurium dioxide, forming a white sublimate, which B.B. fuses into colorless drops. On charcoal in R.F. colors the flame bluish, fuses to a globule, coats the coal near the assay with a lustrous metallic ring of lead telluride, outside of which it is brownish yellow, and in O.F. still more yellow. Entirely volatile, except a trace of silver.

**Obs.**—From the Savodinski mine near Zyrianovski, in the Altai, with hessite. Also in Coquimbo, Chili, at the Condorriaco mine.

In California at the Stanislaus mine, and the Golden Rule mine, Calaveras Co.; in Colorado at the Red Cloud mine, Boulder county, with native tellurium, sylvanite, pyrite, siderite, quartz. North Carolina, at the King's Mountain mine, Gaston Co., in saccharoidal quartz with gold, galena, pyrite, tetrahedrite, and rarely nagyagite.

Named after the original locality.

HENRYITE *Endlich*, Eng. Mng. J., Aug. 29, 1874. An impure altaite, containing admixed pyrite (Genth).

**47. CLAUSTHALITE.** Selenblei *Zinken*, 1823, Pogg., **2**, 415, 1824, 3, 271; *H. Rose*, ib., **2**, 415, 3, 281. Plomb séléniè *Fr.* Clausthalie *Beud.*, Tr., **2**, 531, 1832. Clausthalite. Kobalt-Bleiglanz *Hausm.*, Nordd. Beitr. B. H., 3, 120. Kobaltbleierz *Hausm.*, Handb., 183, 1813; id. *Strom. & Hausm.*, Gött. gel. Anz., 329, 1825. Selenkobaltblei *H. Rose*, Pogg., 3, 288, 290. Tilkerodite *Haid.*, Handb., 566, 1845.

Isometric. Occurs commonly in fine granular masses; some specimens foliated.

Cleavage: cubic. Fracture granular. H. = 2·5–3. G. = 7·6–8·8. Luster metallic. Color lead-gray, somewhat bluish. Streak darker. Opaque.

**Comp., Var.**—Lead selenide, PbSe = Selenium 27·7, lead 72·3 = 100.

*Tilkerodite* Haid., is a cobaltiferous variety; it gave Rose 3·14 p. c. Co. Analyses 5th Ed., p. 43.

**Pyr.**—Decrepitates in the closed tube. In the open tube gives fumes of selenium and a red sublimate. B.B. on charcoal a strong odor of selenium; partially fuses. Coats the coal near the assay at first gray, with a reddish border (selenium), and later yellow (lead oxide); when pure entirely volatile; with soda gives a globule of metallic lead. The *tilkerodite* yields a black residue, and gives a cobalt-blue bead with borax.

**Obs.**—Much resembles a granular galena. Found by Zinken, near Harzgerode, in the Harz with hematite, at Clausthal, Tilkerode, Zorge, and Lehrbach; at Reinsberg, near Freiberg, in Saxony; at the Rio Tinto mines near Seville, Spain; Cacheuta mine, Mendoza, S. A.

**48. NAUMANNITE.** Selensilber *G. Rose*, Pogg., **14**, 471, 1828. Selenbleisilber, Selensilberglanz. Séléniure d'Argent *Fr.* Naumannit *Haid.*, Handb., 565, 1845.

Isometric. In cubes. Also massive, granular, and in thin plates.

Cleavage: cubic, perfect. H. = 2·5. G. = 8·0. Luster metallic, splendent. Color and streak iron-black.

**Comp.**—A selenide of silver, or of silver and lead, $(Ag_2,Pb)Se$. If pure, $Ag_2Se$ = Selenium 26·8, silver 73·2 = 100.

**Anal.**—1, Rose, l. c. 2, Rg., Min. Ch., 34, 1860.

| | | | | | |
|---|---|---|---|---|---|
| 1. Tilkerode | G. = 8·0 | Se [29·53] | Ag 65·56 | Pb 4·91 | = 100 |
| 2. " | | 26·52 | 11·67 | 60·15 | = 98·34 |

No. 2 corresponds nearly to $Ag_2Se.5PbSe$ and approximates to clausthalite. Domeyko (C. R., 63, 1064, 1866) obtained for an ore from Cacheuta: Se 30·0, Ag 21·0, Pb 43·5, Cu 1.8, Co 0·7, Fe 2·2 = 99·2. Adam calls this *cacheutaite*, Tabl. Min., 52, 1869.

**Pyr., etc.**—B.B. on charcoal melts easily in the outer flame; in the inner, with some intumescence. With soda and borax yields a bead of silver.

**Obs.**—Occurs at Tilkerode in the Harz.

Named after the crystallographer and mineralogist, C. F. Naumann (1797–1873).

According to Del Rio, another selenide of silver occurs at Tasco in Mexico, crystallized in hexagonal tables. Beud., Tr., **2**, 535, 1832.

**49. BERZELIANITE.** Selenkupfer *Berz.*, Afh., **6**, 42, 1818. Cuivre séléniè *Fr.* Berzeline *Beud.*, Tr., **2**, 534, 1832. Berzelianite *Dana*, Min., 509, 1850.

In thin dendritic crusts and disseminated.

Soft. G. = 6·71. Luster metallic. Color silver-white, soon tarnishing. Streak shining.

**Comp.**—Copper selenide, $Cu_2Se$ = Selenium 38·4, copper 61·6 = 100.

**Anal.**—Nordenskiöld, Öfv. Ak. Stockh., 23, 364, 1866.

| | Se | Cu | Ag | Fe | Tl |
|---|---|---|---|---|---|
| 1. | 39·85 | 53·14 | 4·73 | 0·54 | 0·38 = 98·64 |
| 2. | 38·74 | 52·15 | 8·50 | 0·35 | *tr.* = 99·74 |

Nordenskiöld remarks that the varying percentage of the silver is possibly due to an admixture of eucairite, and that the amount of thallium in the analyses is probably too low.

**Pyr.**—In the open tube gives a red sublimate of selenium, with white crystals of selenium dioxide. B.B. on charcoal fumes of selenium, and with soda yields a globule of copper.

**Obs.**—Occurs at Skrikerum in Sweden disseminated through calcite as a black or blackish-blue powder, also in crusts; also near Lehrbach in the Harz.

Named after the Swedish chemist, J. J. Berzelius (1779–1848).

**50. LEHRBACHITE.** Selenblei mit Selenquecksilber *H. Rose*, Pogg., **2**, 418, 1824, **3**, **297**, 1825. Selen-Quecksilberblei *Leonh.*, Handb., 592, 1826. Lehrbachite *B. & M.*, Min., 153, 1852. Lerbachite.

Massive, granular.

Brittle. G. = 7·804–7·876. Color lead-gray, steel-gray, iron-black.

**Comp.**—Selenide of lead and mercury, PbSe with HgSe.

**Anal.**—1, Rose, l. c. 2, 3, Schultz, Rg., Min. Ch., 1011, 1860.

| | | Se | Pb | Hg |
|---|---|---|---|---|
| 1. Tilkerode | | 24·97 | 55·84 | 16·94 = 97·75 |
| 2. " | G. = 7·089 | 27·68 | 61·70 | 8·33, S 0·80, $Fe_2O_3$ 0·64 = 99·15 |
| 3. " | G. = 8·104 | 24·41 | 16·93 | 55·52, S 1·10 = 97·96 |

**Pyr.**—In the closed tube gives a lustrous metallic gray sublimate of mercury selenide; with soda, a sublimate consisting of globules of mercury. In the open tube gives reactions for selenium, and a sublimate of selenate of mercury condensing in drops. On charcoal like clausthalite.

**Obs.**—From Tilkerode and Lehrbach, in the Harz.

**51. EUCAIRITE.** Eukairit *Berz.*, Afh. **6**, 42, 1818. Cuivre sélénié argental *H.* Selenkupfersilber *Germ.*

Isometric. Massive and granular; also in black metallic films, staining the calcite in which it is contained.

H. = 2·5. G. = 7·50. Luster metallic. Color between silver-white and lead-gray. Streak shining.

**Comp.**—A selenide of copper and silver, $Cu_2Se.Ag_2Se$ = Selenium 31·6, copper 25·3, silver 43·1 = 100.

Analyses by Berzelius and Nordenskiöld agree rather closely, 5th Ed. pp. 39, 797.

**Pyr., etc.**—B.B. gives copious fumes of selenium, and on charcoal fuses readily to a gray metallic globule, leaving a bead of silver selenide. With borax a copper reaction. Dissolves in boiling nitric acid.

**Obs.**—Occurs in small quantities in the Skrikerum copper mine in Småland, Sweden, in a kind of serpentine rock, embedded in calcite. In Chili at Aguas Blancas, near Copiapo, and at the mines of Flamenco, a few leagues north of Trespuntas, in the desert of Atacama. Also on the east side of the Andes of Chili, in the province of San Juan, where it occurs in a narrow vein (10–12 mm. broad), and has a lead-gray color, tarnishes easily, and is partly granular, and partly very imperfectly lamellar; at the Cacheuta mine, in the province of Mendoza, Argentine Repub., with other selenides. Domeyko has examined the selenides from Cacheuta in the province of Mendoza (C. R., **63**, 1064, 1866), and considers them to consist of mixtures or combinations of three selenides: (A) A compound analogous to eucairite; (B) a selenide of cobalt and iron; and (C) a selenide of lead. See 5th Ed. p. 798, cf. Naumannite.

Named by Berzelius from εὐκαίρως, *opportunely*, because found by him soon after the discovery of the metal selenium.

**52. ZORGITE.** Selenblei mit Selenkupfer *H. Rose*, Pogg., **2**, 415, 1824. Selenkupferblei, Selenbleikupfer, *Rose*, ib., 3, 293, 294, 296. Zorgite *B. & M* 153, 1852. Raphanosmit *Kbl.*, Taf., 6, 1853. Glasbachite *Adam*, Tabl. Min., 52, 1869.

Massive, granular, like clausthalite.

Brittle. H. = 2·5. G. = 7–7·5. Luster metallic. Color dark or light lead-gray, sometimes inclining to reddish, and often with a brass-yellow or blue tarnish. Streak darker.

**Comp.**—A selenide of lead and copper in varying amounts; perhaps only a mixture of clausthalite with other ingredients.

**Anal.**—1, 2, H. Rose, Pogg., **3**, 290, 1825. 3, 4, Kersten, ib., **46**, 265, 1839. 5, Billandot, J. Ch. Soc., **42**, 1269, 1882.

| | Se | Pb | Cu | Ag | |

| 5. Argentine R. | 30·80 | 41·0 | 15·0 | — | Hg 1·66, Fe 6·0, sand 4·6 = 99·06 |

No. 1 is Rose's *Selenbleikupfer*, No. 2 his *Selenkupferblei*.

**Pyr.**—Like clausthalite, but yielding a black residue and a globule of copper, with usually, when cupelled, a trace of silver.

**Obs.**—Occurs under similar circumstances with clausthalite at Tilkerode and Zorge in the Harz; at Glasbach near Gabel in Thuringia, in argillaceous schist with galena, chalcopyrite, malachite, in a gangue of calcite, siderite, fluorite, and quartz. With azurite, malachite, chrysocolla at Cacheuta, Mendoza, Argentine Republic.

Other analyses of the South American selenides by Pisani (C. R., **88**, 391, 1879), and by Heusler, Klinger and Wittkopf (Ber. Ch. Ges., **18**, 2556, 1885), show a varying composition due to admixture. Analyses: 1–4, Pisani. 5–8, H. & K. 9, 10, Wittkopf.

| | Se | Pb | Cu | Ag | |
|---|---|---|---|---|---|
| 1. G. = 5·5 | 48·4 | 30·6 | 20·6 | — | gangue 1·2 = 100·8 |

[a] Incl. Co

Pisani calls the locality the Peruvian Andes, but (as noted by H. & K.) the specimens probably came from Cacheuta, Mendoza, Argentine Republic, like those examined by Domeyko, 5th Ed. p. 798 (cf. also Naumannite). They consist in part of a light-colored nearly silver-white mineral and another dark and lead-colored. *Cacheutaite*, Adam, belongs here.

### 53. CROOKESITE. *A. E. Nordenskiöld*, Öfv. Ak. Stockh., 23, 365, 1866.

Massive, compact; no trace of crystallization.

Brittle. H. = 2·5–3. G. = 6·90. Luster metallic. Color lead-gray.

**Comp.**—A selenide of copper and thallium with a small amount of silver, $(Cu,Tl,Ag)_2Se$.

**Anal.**—Nordenskiöld:

| | Se | Cu | Ag | Fe | Tl |
|---|---|---|---|---|---|
| 1. | [33·27] | 46·11 | 1·44 | 0·63 | 18·55 = 100 |
| 2. | 30·86 | 46·55 | 5·04 | 0·36 | 16·27 = 99·08 |
| 3. | 32·10 | 44·21 | 5·09 | 1·28 | 16·89 = 99·57 |

**Pyr., etc.**—B.B. fuses very easily to a greenish black shining enamel, coloring the flame strongly green. Insoluble in hydrochloric acid; completely soluble in nitric acid.

**Obs.**—From the mine of Skrikerum in Sweden. Formerly regarded as copper selenide or berzelianite. Named after Wm. Crookes, the discoverer of the metal thallium.

The Galena Group also includes the silver sulpho-selenide, *Aguilarite*, $Ag_2S.Ag_2Se$, from Guanajuato, Mexico. See p. 1025.

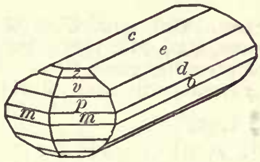
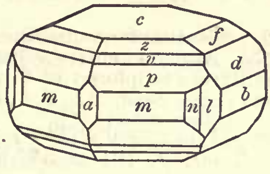
1.



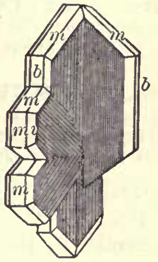
Bristol.

2.



Joachimsthal, Vrba.

3.

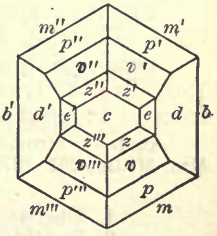


Bristol, J. D. D.

Twins: (1) tw. pl. *m*, producing pseudo-hexagonal stellate forms, sometimes drillings; (2) (032) cruciform twins, crossing at angles of 111° and 69°; (3) *v* (112). Simple crystals often hexagonal in aspect. Faces *c* striated ‖ edge *b*/*c*; also *c*, *d* in oscillatory combination. Also massive, structure granular to compact and impalpable.

Cleavage: *m* indistinct. Fracture conchoidal. Rather brittle. H. = 2·5–3. G. = 5·5–5·8; 5·702 Thomson; 5·648 Ural, Erem. Luster metallic. Color and streak blackish lead-gray, often tarnished blue or green, dull. Opaque.

4.



Bristol.

**Comp.**—Cuprous sulphide, $Cu_2S$ = Sulphur 20·2, copper 79·8 = 100.

Most analyses (5th Ed. pp. 52, 53) agree closely with this formula; sometimes iron in small amount is present, also a little silver.

**Pyr., etc.**—Yields nothing volatile in the closed tube. In the open tube gives off sulphurous fumes. B.B. on charcoal melts to a globule, which boils with spirting; the fine powder roasted at a low temperature on charcoal, then heated in R.F., yields a globule of metallic copper. Soluble in nitric acid.

**Obs.**—Cornwall affords splendid crystals where it occurs in veins and beds with other ores of copper, and especially in the districts of Saint Just, Camborne, and Redruth (*redruthite*). It occurs also at Fassnetburn in Haddingtonshire, in Ayrshire, and in Fair Island, Scotland. In crystals (f. 2) at Joachimsthal, Bohemia. In Tellemarken, Norway. The compact and massive varieties occur in Siberia, Hesse, Saxony, the Banat, etc.; Mt. Catini mines in Tuscany; Mexico, Peru, Bolivia, Chili. Near Angina, Tuscany, a crystal has been obtained, weighing half a pound.

In the United States, compact varieties occur in the red sandstone at Simsbury and Cheshire, Conn.; also at Schuyler's mines, N. J. Bristol, Conn., has afforded large and brilliant crystals. In Virginia, in the United States copper mine district, Blue Ridge, Orange Co. Between Newmarket and Taneytown, Maryland, east of the Monocacey, with chalcopyrite. In Arizona, near La Paz; in N. W. Sonora. In Nevada, in Washoe, Humboldt, Churchill and Nye counties. In Montana, massive at Butte City. In Canada, with chalcopyrite and bornite at the Acton mines and elsewhere in the province of Quebec; at the Canada West mines, L. Huron and Prince's location, L. Superior. In Nova Scotia, in nodules in sandstone.

The *Argent en epis* or *Cuivre spiciforme* of Haüy, which is merely vegetable matter impregnated with this ore, occurs at Frankenberg in Hessia, and also Mahoopeny, Penn.

Under the name *Cupreine* (coperite *Domeyko*), Breithaupt separated the larger part of the specimens, referred to chalcocite, on the ground alleged that they were *hexagonal* instead of orthorhombic, and had a lower specific gravity, but his conclusions were doubtless erroneous.

**Alt.**—Occurs altered to chalcopyrite, bornite, covellite, and melaconite.

Specimens are often penetrated with the covellite, or indigo-copper, resulting from the alteration. *Digenite* of Breithaupt (l. c.) is probably a mineral of this kind. *Carmenite* of Hahn from Carmen island, in the Gulf of California, approaches digenite. It is an impure chalcocite, containing visibly much covelite. Lindström has analyzed a mineral of apparently the same nature from Sunnerskog; G. För. Förh., **7**, 678, 1885

HARRISITE of Shepard from Canton mine, Georgia, and the Polk Co. copper mines in East Tennessee, is chalcocite with the cleavage of galena, and, as Genth has proved, is pseudomorphous after galena. Unaltered galena has been observed within crystals of harrisite both at the Georgia and Tennessee localities. Its color is dark lead-gray and bluish black. Named for W. F. Harris. See further on the above in 5th Ed. p. 53.

**Artif.**—Chalcocite has been formed by Durocher by the action of sulphuretted hydrogen gas on vapors of copper chloride. Cf. Doelter, Zs. Kr., **11**, 34, 1885, also Fouqué-Lévy, Synth. Min., 294, 1882. Formed as a recent product on Roman coins at Bourbonne-les-Bains (Daubrée) and elsewhere.

The artificial $Cu_2S$ belongs in part to the isometric system, Mitsch.

**Ref.**—[1] Min., 159, 1852. [2] J. D. D., Min., 46, 1854. 52, 1868; for the twin (2) the angles given correspond to (032), not (043). On Joachimsthal crystals (f. 2) cf. Vrba, Zs. Kr., **15**, 208, 1888; on those from the Tugrinsk copper mines in the Ural, Erem., Vh. Min. Ges., **25**, 315, 1889.

**55. STROMEYERITE.** Silberkupferglanz *Hausm. & Strom.*, Gel. Anz. Gött., **2**, 1249, 1816; Schw. J., **19**, 325, 1817. Argent et cuivre sulfuré *Bournon*, Cat., 212, 1817. | 4. Zacatecas | | G. = 6·230 | 15·81 | 50·18 | 33·69 | insol. 0·26 = 99·94 |

**Pyr., etc.**—Fuses, but gives no sublimate in the closed tube. In the open tube sulphurous fumes. B.B. on charcoal in O.F. fuses to a semi-malleable globule, which, treated with the fluxes, reacts strongly for copper, and cupelled with lead gives a silver globule. Soluble in nitric acid.

**Obs.**—Found associated with chalcopyrite at the Zmeinogorsk mine, near Kolyvan in Siberia; at Rudelstadt, Silesia; also in Chili; at Combavalla in Peru; on the Hoyada, province of Catamarca, Argentine Republic, with chalcopyrite and galena; Zacatecas, Mexico; at the Heintzelman mine in Arizona. Reported from the Black Prince mine, Summit Co., Colorado, and the Yankee Girl mine, Ouray Co.; cf. also p. 58.

Named after Fr. Stromeyer (1776–1835), Professor of Chemistry at Göttingen, who first analyzed and established the species.

**Ref.**—[1] Pogg., **28**, 427, 1833. [2] Min., p. 158, 1852; Rose says twins as with chalcocite.

**Pyr., etc.**—In the open tube sulphurous fumes. B.B. on charcoal gives off sulphur and fuses to a magnetic globule, the surface of which shows separated metallic silver. The washed mineral, treated with the fluxes, gives reactions for iron; on charcoal yields a globule of metallic silver. Soluble in aqua-regia with separation of sulphur and silver chloride.

**Obs.**—*Sternbergite* occurs with ores of silver, particularly pyrargyrite and stephanite, at Joachimsthal in Bohemia, and Johanngeorgenstadt in Saxony, also at Schneeberg (Breith.). Named after Count Caspar Sternberg of Prague.

The *Flexible silver ore* (*Argent sulfuré flexible* Bourn., *biegsamer Silberglanz* Germ.) from the Himmelsfürst mine, near Freiberg, is referred here.

*Frieseite* occurs with dolomite, proustite, and pseudomorphs of "Silberkies" (see below, Tsch.) on massive marcasite at Joachimsthal; the crystals of frieseite and "Silberkies" sometimes in parallel position.

**Ref.**—[1] Min., p. 180, 1852; see earlier Haid., l. c., or Pogg., **11**, 483, 1827. [2] L. c. and Zs. Kr., **5**, 426, 1881; for *q* the symbol (043) and angle given do not agree, viz., *cq* = 47° 28′ meas.

ARGENTOPYRITE. Silberkies *S. v. Waltershausen*, Nachr. Ges. Gött., **9**, 66, 1866.

Described as monoclinic; in six-sided twin crystals. No cleavage Fracture uneven. Brittle. H. = 3·5–4. G. = 6·47(?). Luster metallic. Color steel-gray to tin-white; tarnishing. Analysis (6) below. From Joachimsthal.

Tschermak[1] later described pseudomorphs in small hexagonal crystals consisting of argentite, marcasite, pyrrhotite and pyrargyrite, which he regarded as being the argentopyrite of v. Waltershausen. Schrauf[2], however, sustained the latter species making it orthorhombic, but pseudo-hexagonal by repeated twinning.

Axes $\breve{a} : \bar{b} : \acute{c}$ = 0·5812 : 1 : 0·2749, or near that of sternbergite if $\acute{c}$ be multiplied by 3. Forms: *b*, *c*, *m*, *n* (130), *y* (011), *x* (021), *p* (111), *π* (421). Angles: *mm‴* = *60° 20′, *cy* = 15° 22′, *bx* = *61° 12′, *cp* = 28° 45′ (= *c* ∧ 113 sternbergite). Silver = 22·3 p. c.

Streng[3] has also described a "SILBERKIES" from Andreasberg, occurring in prismatic crystals, pseudo-hexagonal by twinning, with the planes *m*, *n*, *x* (as above). No cleavage. Fracture uneven. Rather brittle. H. = 3·5–4. G. = 4·18. Luster metallic, brilliant. Color bronze-yellow, tarnishing on surface. Weak magnetic. Analysis (7) below. Weisbach[4] has described a similar mineral from Marienberg, like the above in form. Brittle. G. = 4·06–4·12. Also another from the Himmelsfürst mine, Freiberg, similar in form but with cleavage ∥ *c*; crystals often grouped in hemispherical forms. Not brittle. G. = 4·206. Color on fresh fracture bronze-yellow. Analysis by Winkler (8) below. To these varieties the name ARGYROPYRITE was attached.

**Anal.**—6, Waltershausen, l. c. 7, Streng, l. c. 8, Winkler, Jb. Min., 908, 1877.

| | S | Ag | Fe |
|---|---|---|---|
| 6. Joachimsthal, *Argentopyrite* | [34·2] | 26·5 | 39·3 = 100 |
| 7. Andreasberg, "*Silberkies*" | 30·71 | 32·89 | 35·89 Cu 0·19 = 99·68 |
| 8. Freiberg, *Argyropyrite* | 32·81 | 29·75 | 36·28 = 98·84 |

The relations of the above minerals are yet uncertain. It seems probable that there may be two independent species: 1, *Sternbergite* (including frieseite) usually in tabular crystals, cleavable, soft, flexible; and 2, *Argentopyrite* usually in prismatic, pseudo-hexagonal forms, without cleavage, harder, brittle. The fact that the two forms occur together seems to point to this. The "argyropyrite" from Freiberg seems to be intermediate between them. The variation in composition is probably more apparent than real. Streng suggested the formula $Ag_2S + pFe_nS_{n-1}$ for the group (i.e. acanthite + pyrrhotite), but no simple numerical relation exists and pyrrhotite is yet to be shown to be other than true hexagonal in form.

**Ref.**—[1] Ber. Ak. Wien, **54** (1), 342, 1866. [2] Ib., **64** (1), 192, 1871. [3] Jb. Min., 785, 1878. [4] Ib., 906, 1877.

## 57. ACANTHITE. Akanthit *Kenng.*, Ber. Ak. Wien, **15**, 238, 1855, Pogg., **95**, 462, 1855.

Orthorhombic. Axes $\breve{a} : \bar{b} : \acute{c}$ = 0·6886 : 1 : 0·9944 Dauber[1].

100 ∧ 110 = 34° 33′, 001 ∧ 101 = 55° 17$\frac{5}{6}$′, 001 ∧ 011 = 44° 50$\frac{1}{3}$′.

**Forms:**
*a* (100, *i*-ī)
*b* (010, *i*-ĭ)
*c* (001, *O*)
*τ* (210, *i*-2̄
*m* (110, *I*)
*α* (120, *i*-2̆)
*o* (101, 1-ī)
*γ* (504, $\frac{5}{4}$-ī)
*u* (201, 2-ī)
*e* (301, 3-ī)
*d* (011, 1-ĭ)
*x* (113, $\frac{1}{3}$)
*p* (111, 1)
*z* (554, $\frac{5}{4}$)
*χ* (214, $\frac{1}{2}$-2̄)
*n* (211, 2-2̄)

*s* (131, 3-3̆)
*λ* (143, $\frac{4}{3}$-4̆)
*ω* (141, 4-4̆)[2]
*β* (152, $\frac{5}{2}$-5̆)
*π* (161, 6-6̆)[2]
*θ* (163, 2-6̆)
*ε* (183, $\frac{8}{3}$-8̆)

Also doubtful *φ* (508, $\frac{5}{8}$-ī), *t*(203, $\frac{2}{3}$-ī), *i*(506, $\frac{5}{6}$-ī), *ψ* (801, 8-ī), *y* (518, $\frac{5}{8}$-5), *σ* (14·15·13, $\frac{15}{13}$-$\frac{15}{14}$), *g* (8·20·1, 20-$\frac{5}{2}$).

Krenner shows the close correspondence between the angles of acanthite, as given by Dauber, and those required by the isometric system, and argues from this that the crystals of acanthite are simply distorted forms of argentite. This conclusion seems plausible (cf. gold, silver, also hessite), but cannot be regarded as proved, cf. Zs. Kr., **14**, 388, 1888.

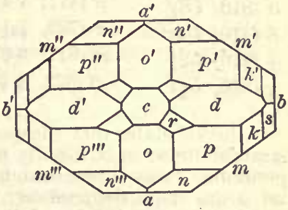
Twins: tw. plane *o*. Habit prismatic, crystals usually slender; sometimes monoclinic, in development of planes.

Cleavage indistinct. Fracture uneven. Sectile. H. = 2–2·5. G. = 7·2–7·3; 7·196, Freiberg, 7·246, Joachimsthal, Dbr. Luster metallic. Color iron-black. Opaque.

**Comp.**—Silver sulphide like argentite, $Ag_2S$ = Sulphur 12·9, silver 87·1 = 100.



Freiberg, Dbr.

**Pyr.**—As for argentite.

**Obs.**—At Joachimsthal, with pyrite, argentite, and calcite, usually on quartz; also at the Himmelsfürst and other mines, near Freiberg in Saxony, along with argentite and stephanite. A specimen found in 1860 shows brilliant crystals 22mm. long. At Schneeberg with native silver and argentite.

Named from ἄκανθα *thorn*, in allusion to the shape of the crystals.

**Ref.**—[1] Crystals from Himmelsfürst mine, Ber. Ak. Wien, **39**, 685, 1857. [2] Groth, Annaberg, crystals with marked monoclinic symmetry, Min. Samml., 51, 1878.

**Artif.**—A silver sulphide, $Ag_2S$, in acicular crystals resembling acanthite has been obtained by Weinschenk, Zs. Kr., **17**, 497, 1890.

DALEMINZITE *Breith.*, B. H. Ztg., **21**, 98, 1862, **22**, 44, 1863. Silver sulphide ($Ag_2S$) in an orthorhombic form regarded as distinct from acanthite; crystals short prisms with 010, 001, 110, 121, with *mm'''* = 64°. G. = 7·049. It may be a pseudomorph after stephanite, cf. Frenzel, Min. Lex. Sachs., 76, 1874. Found in 1858 at the Himmelfahrt mine at Freiberg with argentite.

Becke[1] states that the positive octants are poor in planes, the faces even, or striated with straight lines; $m$ is usually positive. In the negative octants the secondary planes are more common, faces often rounded or with vicinal elevations. The etching figures on $o$ (+ 1) and on $a$ are deep depressions; on $o_{,}$ ($-$ 1) and on $d$ they are acute elevations. In general the etching-figures developed belong to the positive octants. The size and luster of the faces does not serve to distinguish the positive and negative octants. Observations of Krenner do not entirely agree with the above[9].

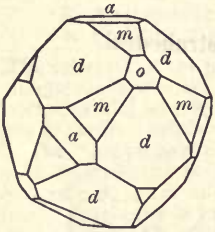
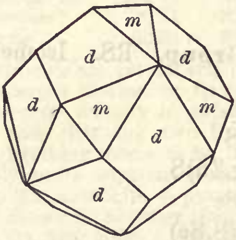
4.



5.



6.

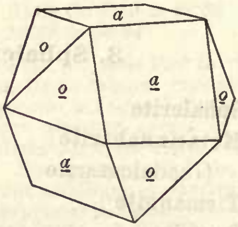


Fig. 1, Bottino, Becke. 2, St. Agnes, Id. 3, Schemnitz, Sbk. 5, Lockport. 6, Freiberg, Sbk.

Twins: tw. pl. $o$, the comp. face usually ∥ $o$, but also ⊥ $o$. Twinning often repeated, and sometimes producing narrow polysynthetic lamellæ. Crystals frequently highly complex and distorted, sometimes resembling rhombohedral forms; the faces $d$, $m$ often rounded together into a low conical form. Commonly massive cleavable, coarse to fine granular and compact; also foliated, sometimes fibrous and radiated or plumose; also botryoidal and other imitative shapes. Cryptocrystalline to amorphous, the latter sometimes as a powder.

Cleavage: dodecahedral, highly perfect. Fracture conchoidal. Brittle. H. = 3·5–4. G. = 3·9–4·1; 4·063 white, N. J. Luster resinous to adamantine. Color commonly yellow, brown, black; also red, green to white, and when pure nearly colorless. Streak brownish to light yellow and white. Transparent to translucent. Refractive indices, Ramsay[10]:

$$n_r = 2{\cdot}34165 \text{ Li} \qquad n_y = 2{\cdot}36923 \text{ Na} \qquad n_{gr} = 2{\cdot}40069 \text{ Tl}$$

Sometimes shows abnormal double refraction. Pyro-electric, polar in the direction of the trigonal axes, Friedel[11].

**Comp.**—Zinc sulphide, ZnS = Sulphur 33, zinc 67 = 100. Often containing iron and manganese, and sometimes cadmium, mercury and rarely lead and tin. Also sometimes contains traces of indium, gallium and thallium; may be argentiferous and auriferous.

**Var.**—1. *Ordinary.* Containing little or no iron; colors white to yellowish brown, sometimes black; G. = 4·0–4·1. The pure white blende of Franklin, N. J., is the *cleiophane* (anal. 1). A kind occurring at Nordmark, Sweden, in snow-white crystals, consists of pure ZnS with neither Fe nor Mn. The red or reddish brown transparent crystallized kinds are sometimes called *ruby blende* or *ruby zinc.*

The massive cleavable forms are the most common, varying from coarse to fine granular; also cryptocrystalline. *Schalenblende* (Germ., also *Leberblende*) is a closely compact variety, of a pale liver-brown color, occurring in concentric layers with reniform surface; galena and marcasite are often interstratified. The fibrous forms (*faserige Zinkblende* Germ.) are chiefly wurtzite (p 70). Rarely occurs as a soft white amorphous deposit, resembling the zinc sulphide precipitated by hydrogen sulphide in the laboratory, cf. below.

2. *Ferriferous; Marmatite.* Containing 10 p. c. or more of iron; dark-brown to black; G. = 3·9–4·05. The proportion of FeS to ZnS varies from 1 : 5 to 1 : 2, and the last ratio is that of the *christophite* of Breithaupt, a brilliant black sphalerite (anal. 11) from St. Christophe mine, at Breitenbrunn, near Johanngeorgenstadt, having G. = 3·91–3·923. A similar variety from St. Agnes, Cornwall, gave Collins 26 p. c. Fe, Min. Mag., **3**, 91, 1879.

3. *Cadmiferous; Přibramite, Przibramite.* The amount of cadmium present in any sphalerite thus far analyzed is less than 5 per cent.

4. *Mercurial.* A specimen from Aviles, Asturia, yielded Soltsien, 0·135 p. c. Hg, Jb. Min., **2**, 272 ref., 1887; other sphalerites (Sweden, Rhine) have given 0·02 p. c.

5. *Stanniferous.* Specimens of the black sphalerite from Freiberg, with 12–13·4 p. c. Fe and G. = 3·95–3·99, yielded 0 06–0·55 p. c, Sn, present as sulphide, also some cassiterite as impurity. Cf. Stelzner and Schertel, Zs. Kr., **14**, 398, 1888.

On the sulphides of lead and zinc which are probably to be regarded as mixtures of galena and sphalerite, see huascolite, kilmacooite, p. 51. The *brass-ore*, Messingerz *Germ.*, of early mineralogists is a mixture of sphalerite and chalcopyrite. Shepard's *marasmolite* is a partially decomposed sphalerite containing some free sulphur.

**Pyr., etc.**—In the open tube sulphurous fumes, and generally changes color. B.B. on charcoal, in R.F., some varieties give at first a reddish brown coating of cadmium oxide, and later a coating of zinc oxide, which is yellow while hot and white after cooling. With cobalt solution the zinc coating gives a green color when heated in O.F. Most varieties, after roasting, give with borax a reaction for iron. With soda on charcoal in R.F. a strong green zinc flame. Difficultly fusible.

Dissolves in hydrochloric acid with evolution of hydrogen sulphide. Some specimens phosphoresce when struck with a steel or by friction.

**Obs.**—Occurs very commonly in both crystalline and sedimentary rocks, and as a frequent associate of galena; also associated with chalcopyrite, barite, fluorite, siderite; common in silver mines. It often forms beds of considerable magnitude filling cavities in limestone. Crystals of sphalerite have been observed associated in parallel position with tetrahedrite, also with chalcopyrite (cf. Becke, Min. Mitth., **5**, 331, 1883).

Some of the chief localities for crystallized sphalerite are: Alston Moor in Cumberland, black variety; Derbyshire, St. Agnes and elsewhere in Cornwall; Oberlahnstein in Nassau, Ems, red; Andreasberg, yellow and brown; Neudorf in the Harz, Freiberg, Breitenbrunn and other localities in Saxony, black and brown; Přibram, green or yellow, and Schlackenwald in Bohemia, black; Kapnik in Hungary, green or yellow; Nagyág in Transylvania, brown; Rodna, black; the Binnenthal in Switzerland, isolated crystals of great beauty, yellow to brown in color, in cavities of dolomite; Sala in Sweden; Nordmark, black, brown and also snow-white. A beautiful transparent variety yielding large cleavage masses is brought from Picos de Europa, Province of Santander, Spain, where it occurs in a brown limestone. Fibrous varieties (see wurtzite) are obtained at Přibram, Geroldseck in Baden, Raibel; also in Cornwall. The original *Marmatite* is from Marmato near Popayan, Italy. Large beds occur at Åmmeberg on Lake Wetter in Sweden. The new element gallium was first identified in the sphalerite of the Pierrefitte mine, Vallée d'Argelès, Pyrenees, L. de Boisbandran, C. R., **81**, 493, 1875.

Abounds with the lead ore of Missouri, Wisconsin, Iowa, and Illinois. In *N. York*, Sullivan Co., near Wurtzboro', it constitutes a large part of a lead vein in millstone grit, and is occasionally in octahedrons; in St. Lawrence Co., occurs at Cooper's falls; at Mineral Point with galena, and in Fowler, on the farm of Mr. Belmont, in a vein with iron and copper pyrites traversing serpentine; at the Ancram lead mine in Columbia Co., of yellow and brown colors; in limestone at Lockport and other places, in honey and wax-yellow crystals often transparent; with galena on Flat Creek, two miles south-west of Spraker's Basin. In *Mass.*, at Sterling, of a cherry-red color, with galena; also yellowish brown at the Southampton lead mines; at Hatfield, with galena. In *N. Hamp.*, at the Eaton lead mine; at Warren, a large vein of black blende. In *Maine*, at the Lubec lead mines; also at Bingham, Dexter, and Parsonsfield. In *Conn.*, yellowish-green at Brookfield; at Berlin, of a yellow color; brownish black, sometimes finely crystallized at Roxbury, and yellowish brown at Lane's mine, Monroe. In *N. Jersey*, a *white* variety (*cleiophane* of Nuttall) at Franklin Furnace. In *Penn.*, at the Wheatley and Perkiomen lead mines, in handsome crystallizations; near Friedensville, Lehigh Co., a *white* waxy var. In *Virginia*, at Walton's gold mine, Louisa Co., and more abundantly at Austin's lead mines, Wythe Co., where it occurs crystallized, or in radiated crystallizations. In *Michigan*, at Prince vein, Lake Superior, abundant. In *Illinois*, near Rosiclare, with galena and calcite; at Marsden's diggings, near Galena, in stalactites, some 6 in. or more through, and covered with cryst. marcasite, and galena. In *Wisconsin*, at Mineral Point, in fine crystals, and many of large size (3 in. through, or so), altered to smithsonite. In *Tennessee*, at Haysboro', near Nashville. In *Missouri*, in beautiful crystallizations with galena, marcasite and calcite at Joplin and other points in the southwestern part of the state; the deposits here occur in limestone and are of great extent and value. The original sphalerite in places has been removed and redeposited as calamine or smithsonite, or again as sphalerite, usually in crystals. A variety, formed by reprecipitation, occurs as a soft white powdery mass in Galena, Cherokee Co., southeastern Kansas, adjoining the zinc region of Missouri; the deposit as first exposed extended for 30 feet with a thickness of at least 4 feet. (Am. J. Sc., **40**, 160, 1890.)

Named *blende* because, while often resembling galena, it yielded no lead, the word in German meaning *blind* or *deceiving*. *Sphalerite* is from *σφαλερός*, *treacherous*.

**Alt.**—Sphalerite by oxidation changes to the zinc sulphate, goslarite. Calamine, smithsonite, and limonite occur as pseudomorphs.

**Artif.**—Made in crystals from a solution of sulphate containing some putrifying animal matter; in an experiment by Gages, using oysters for the animal matter, the shells were turned partly into carbonate of zinc and selenite, and some sphalerite incrusted them. Also may be made by subjecting heated oxide or silicate of zinc to vapors of sulphur. Cf. further Fouqué-Lévy, Synth. Min., 297, 1882.

*Rahtite* Shepard is an impure uncrystalline sphalerite, with G. = 4·128, containing iron and copper, see 5th Ed., p. 50.

**Ref.**—[1] See Sbk., Zs. G. Ges., **21**, 620, 1869; **24**, 180, 1872; **30**, 573, 1878; also earlier Hbg., Min. Not., **1**, 28, 1856, Kapnik with *h* and *μ*; **6**, 7, 1864, Cumberland and Schemnitz; Rath, Binnenthal, with *u*, Pogg., **122**, 396, 1864. Later Becke, Min. Mitth., **5**, 457, 1883. The distinction between the planes of the + and − octants was made out by Sbk., and revised and extended by Becke on the basis of etching experiments; the results of the latter (see above) are followed here. Some planes are in doubt as between the + and − position.

[2] Klein, Kapnik, Jb. Min., 492, 1871. [3] Id. Binnenthal, ibid., 897, 1872; Klein called it 722, but Becke's etching makes the prominent tetrahedron for this locality ($1\bar{1}1$) and reverses the position taken by other authors. [4] Sbk., l. c. [5] Groth, Min. Samml., 23, 1878. [6] Becke, l. c. [7] Hintze, Striegau, Zs. Kr., **13**, 161, 1887. [8] Flink, Nordmark, Bihang, Ak. H. Stockh., **13**, (2), No. 7, 15, 1885. **59. METACINNABARITE.** *G. E. Moore* J. pr. Ch., **2**, 319, 1870; Am. J. Sc., **3**, **36**, 1872. Metazinnober *Germ.*

Isometric; tetrahedral. Observed forms[1]:

$o$ (111, + 1) $o_{,}$ ($1\bar{1}1$, − 1) $n$ (211, 2-2) $\beta$ (322, $\frac{3}{2}$-$\frac{3}{2}$) $v$ (975, $\frac{9}{5}$-$\frac{9}{7}$)

Twins: tw. plane *o*, common. Habit tetrahedral, faces rough and unpolished. Also massive; amorphous.

Fracture subconchoidal to uneven. Brittle. H. = 3. G. = 7·81, Pfd., cryst.; 7·701–7·748, Moore, amorphous. Luster metallic. Color grayish black. Streak black. Opaque.

**Comp.**—Mercuric sulphide, like cinnabar, $HgS$ = Sulphur 13·8, mercury 86·2 = 100.

**Anal.**—Moore, l. c.

| | S | Hg | Fe | Quartz | |
|---|---|---|---|---|---|
| 1. | 13·79 | 85·69 | 0·33 | 0·26 | = 100·07 |
| 2. | 13·84 | 85.89 | 0·45 | 0·24 | = 100·42 |

**Pyr.**—See cinnabar.

**Obs.**—From the Reddington mine, Lake county, California, with cinnabar in acicular crystals, quartz and marcasite. Also at the Baker mine near Knoxville; some tons have been found at New Idria, Fresno Co. (Becker). At Huitzuco, Mexico, in pseudomorphs of cinnabar after stibnite (Sandb.). At the mercury mines in the Palatinate. Also reported from Hermsdorf near Waldenburg, Silesia (Traube). Probably at Pakaraka, Bay of Islands, New Zealand, where Hutton in 1870 noted the occurrence of native mercury and a "black ore of mercury . . . . . a sulphide containing some iron." H. = 5, G. = 9·224(?) Trans. N. Z. Inst., **3**, 252, 1870.

Metacinnabarite is the equivalent of the black mercuric sulphide of the laboratory, also called *Æthiops mineral* (Quecksilber-Mohr *Germ.*).

**Ref.**—[1] Pfd., Am. J. Sc., **29**, 452, 1885. Melville has described crystals from New Almaden, Cal., which he regards as rhombohedral and hemimorphic, with $0001 \wedge 10\bar{1}1 = 15° 19'$, Am. J. Sc., **40**, 291 1890, and p. 1041.

GUADALCAZARITE. Schwefelselenquecksilber *Castillo* and *Burkhart*, Jb. Min., 414, 1866. Guadalcazite *Adam*, Tabl. Min., p. 59, 1869. Guadalcazarite *Petersen*, Min. Mitth., 69, 1872; *Burkhart*, ibid., 243.

Near metacinnabarite, but contains a little zinc. Occurs massive, with cinnabar, barite, quartz at Guadalcazar, Mexico. H. = 2. G. = 7·15. Castillo mentions rhombohedral forms.

**Anal.**—1, Petersen, l. c. 2, Rg., Min. Ch. p. 79, 1875.

| | | S | Se | Hg | Zn | Cd | Fe | |
|---|---|---|---|---|---|---|---|---|

| 2. | | 14·01 | *tr.* | 83·90 | 2·09 | — | — | = 100 |

The ratio of Hg : Zn = 6 : 1 in anal. (1), and 12 : 1 in (2).

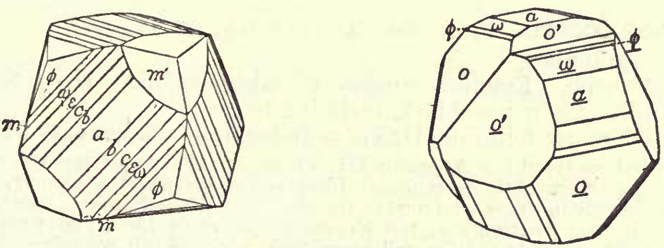
LEVIGLIANITE *D'Achiardi*, Att. Soc. Tosc., **2**, 112, 1876. Stated to be a ferriferous variety of guadalcazarite (metacinnabarite); but not fully examined. From the mercury mines of Levigliani, near Seravezza in the Apuan Alps, Italy.

**60. TIEMANNITE.** Selenquecksilber *Marx*, Schw. J. **54**, 223, 1828. Selenmercur, Tiemannit, *Naumann*, Min., 425, 1855.

Isometric; tetrahedral. Observed forms[1]:

*a* (100, *i-i*); *o* (111, 1), $o_{,}$ ($1\bar{1}1$, – 1); *ω* (511, 5·5), *m* (311, 3·3), *φ* (733, $\frac{7}{8}$-$\frac{7}{8}$); $m_{,}$ ($3\bar{1}1$, – 3-3). Also doubtful *b* (13·1·1), *c* (17·2·2), *ε* (13·2·2).

1. 2.



Utah, Penfield.

Twins: tw. pl. *o*. Crystals tetrahedral in habit, *o* usually dull, $o_{,}$ bright; zone *a b c ε ω φ* striated ‖ intersection-edges; also $m_{,}$ striated ‖ edge $m_{,}/a$. Commonly massive; compact granular.

Cleavage none. Fracture uneven to conchoidal. Brittle. H. = 2·5. G. = 8·19 Utah, cryst.; 8·30–8·47 Clausthal[2]. Luster metallic. Color steel-gray to blackish lead-gray. Streak nearly black. Opaque.

**Comp.**—Mercuric selenide, HgSe = Selenium 28·3, mercury 71·7 = 100.

**Anal.**—1, Penfield, l. c. 2, Petersen, JB. Ch., 919, 1866.

| | | Se | S | Hg | Cd | |
|---|---|---|---|---|---|---|
| 1. | Utah | 29·19 | 0·37 | 69·84 | 0·34 | insol. 0·06 = 99·80 |
| 2. | Clausthal | 24·88 | 0·20 | 75·15 | — | Pb 0·12 = 100·35 |

Earlier analyses (5th Ed., p. 56) were made on more or less impure material.

**Pyr.**—Decrepitates in the closed tube, and, when pure, entirely sublimes, giving a black sublimate, with the upper edge reddish brown; with soda a sublimate of metallic mercury. In the open tube emits the odor of selenium, and forms a black to reddish brown sublimate, with a border of white selenate of mercury, the latter sometimes fusing into drops. On charcoal volatilizes, coloring the outer flame azure-blue, and giving a lustrous metallic coating.

**Obs.**—Occurs with chalcopyrite near Zorge in the Harz; at Tilkerode; near Clausthal. In California, in the vicinity of Clear lake. Near Marysvale, Piute Co., in southern Utah, with barite, manganese oxide and calcite in a vein in limestone, the ore in part 4 feet in thickness. Cf. Becker, U. S. G. Surv., Mon. **13**, 1888. Named after the discoverer, Tiemann.

**Ref.**—[1] Pfd., Am. J. Sc., **29**, 449, 1885. [2] Ibid., p. 453; earlier determinations with G. = 7·1–7·37 were probably made on impure material.

**61. ONOFRITE.** Selenschwefelquecksilber *H. Rose*, Pogg., **46**, 315, 1839. Merkur-Glanz *Breith.*, Char., 316, 1832. Onofrite *Haid.*, Handb., 565, 1845.

Massive; fine granular.

Cleavage none. Fracture conchoidal. Brittle. H. = 2·5. G. = 7·98–8·09, Pfd.[1] Luster metallic. Color and streak blackish gray. Opaque.

**Comp.**—Sulpho-selenide of mercury, Hg(S,Se), with S : Se = 6 : 1, Brush, or 4 : 1, Rose. The first requires: Sulphur 11·5, selenium 4·7, mercury 83·8 = 100; the second: Sulphur 10·6, selenium 6·6, mercury 82·8 = 100.

**Anal.**—1, H. Rose, l. c. 2, Comstock, Am. J. Sc., **21**, 314, 1881.

| | | S | Se | Hg | Zn | Mn | |
|---|---|---|---|---|---|---|---|
| 1. | Mexico | 10·30 | 6·49 | 81·33 | — | — | = 98·12 |
| 2. | Utah | $\frac{2}{2}$ 11·68 | 4·58 | 81·93 | 0·54 | 0·69 | = 99·42 |

**Pyr.**—In the closed tube decrepitates and then gives reactions for sulphur and mercury, coating the tube grayish black and leaving a slight non-volatile residue. In the open tube gives sulphurous fumes and sublimates of mercury and sulpho-selenide of mercury. On charcoal gives copious fumes with selenium odor and a sublimate with metallic luster which touched by R.F. disappears, tingeing the flame azure-blue. Gives faint zinc and manganese reactions.

**Obs.**—Occurs with calcite and barite at San Onofre, Mexico. With the pure mercuric selenide, tiemannite, forming a seam 4 inches wide in limestone near Marysvale, southern Utah.

**Ref.**—[1] Am. J. Sc., **29**, 453, 1885.

Del Rio early called attention to a sulpho-selenide of mercury. He mentions two ores occurring in limestone at Culebras, Mexico (Phil. Mag., 4, 113, 1828), one red, the other gray. These were called *culebrite* and *riolite* (also *rionite* other authors) by Brooke, ib., 8, 261, 1836. No confidence can be placed in Del Rio's chemical determinations. Cf. native selenium, p. 10.

**62. COLORADOITE.** *F. A. Genth*, Am. Phil. Soc., **17**, 115, 1877.

Massive; granular.

Cleavage none. Fracture uneven to subconchoidal. H. = 3. G. = 8·627. Luster metallic. Color iron-black, inclining to gray.

**Comp.**—Mercuric telluride, HgTe = Tellurium 38·5, mercury 61·5 = 100.

The material analyzed (see Appendix III, 5th Ed., p. 29 for analyses) was very impure.

**Pyr.**—In the tube slightly decrepitates, fuses and yields metallic mercury as a sublimate, also tellurium dioxide in drops, and next to the assay metallic tellurium. Soluble in nitric acid.

**Obs.**—Occurs very sparingly at the Keystone, Mountain Lion, and Smuggler mines, in Colorado, with quartz, gold, native tellurium and sylvanite; it sometimes has a columnar structure due to alteration from sylvanite.

**63. ALABANDITE.** Schwarze Blende (fr. Transylvania) *Müller v. Reichenstein*, Phys. Arb. Fr. in Wien, **1**, 2nd Quart., 86, 1784; *Bindheim*, Schrift. Ges. Nat. Fr. Berl., **5**, 452, 1784 (making it comp. of Mn, S, Fe, Ag). Schwarzerz *Klapr.*, Beitr., **3**, 35, 1802. Braunsteinkies *Leonh.*, Tab., 70, 1806 Braunsteinblende [= Manganblende] *Blumenbach*, Handb., **1**, 707, 1807. Manganglanz *Karst.*, Tab., 72, 1808. Manganèse sulfuré *H.*, Tab., **3**, 1809. Schwefel-

Mangan *Germ.* Alabandine *Beud.*, Tr. **2**, 399, 1832. Blumenbachit *Breith.*, B. H. Ztg., **22**, 193, 1866.

Isometric; tetrahedral[1]. In cubes or dodecahedrons with tetrahedral planes; also *n* (211, 2-2). Twins[2]: tw. pl. *o;* sometimes repeated, consisting of five octahedrons. Usually granular massive.

Cleavage: cubic, perfect. Fracture uneven. Brittle. H.=3·5–4. G.=3·95–4·04; 4·036, Mexico. Luster submetallic. Color iron-black, tarnished brown on exposure. Streak green.

**Comp.**—Manganese sulphide, $MnS$ = Sulphur 36·9, manganese 63·1 = 100.

**Pyr.**—Unchanged in the closed tube. In the open tube sulphurous fumes. Roasted on charcoal, the assay is converted into the oxide, which, with the fluxes, gives the reactions of manganese. Soluble in dilute hydrochloric acid, with evolution of hydrogen sulphide.

**Obs.**—Occurs in veins in the gold mines of Nagyág, in Transylvania; also Kapnik and Offenbanya in Hungary, associated with tellurium, rhodochrosite, and quartz; at Gersdorf, near Freiberg, a variety containing a trace of arsenic; in Mexico, at the mine Preciosa in Puebla, with tetrahedrite. From the Morococha mines, Peru. Crystallized and massive on Snake River, Summit county, Colorado, with rhodochrosite, galena, argentite, pyrite.

Named from Alabanda in Caria, Asia Minor.

**Artif.**—Cf. Doelter, Zs. Kr., **11**, 32, 1885, and C. R., **105**, 1372, 1887; also Weinschenk, Zs. Kr., **17**, 500, 1890.

**Ref.**—[1] Peters, Jb. Min., 365, 1861. [2] Schrauf, Nagyág, Pogg., **127**, 348, 1866.

### 64. OLDHAMITE. *Maskelyne*, 1862; Phil. Trans., London, 195, 1870.

Isometric. In small, nearly round spherules, generally coated by calcium sulphate as result of alteration.

Cleavage: cubic. H. = 4. G. = 2·58. Color pale chestnut-brown, transparent when pure. Isotropic.

**Comp.**—Calcium sulphide, $CaS$ = Sulphur 44·5, Calcium 55·5 = 100.

**Anal.**—After deducting foreign matter (enstatite, etc.):

| | Oldhamite. | | Incrustation. | | | | |
|---|---|---|---|---|---|---|---|
| | $CaS$ | $MgS$ | $CaSO_4$ | $CaCO_3$ | troilite | | |
| 1. | 89·37 | 3·25 | 3·95 | 3·43 | — | = | 100 |
| 2. | 90·25 | 3·26 | 4·19 | — | 2·30 | = | 100 |

Maskelyne suggests that the $MgS$ may be considered either as a mechanically mixed ingredient, or as a constituent of the mineral.

**Pyr.**—Readily dissolved in acid with the evolution of hydrogen sulphide and deposition of sulphur.

**Obs.**—Found embedded in enstatite or augite in the Busti meteorite, and apparently also in that of Bishopville, South Carolina. Named after Dr. Oldham, Director (1862) of the Indian Geological Survey.

OSBORNITE *Maskelyne*, Phil. Trans., 198, 1870. Small golden yellow regular octahedrons occurring in oldhamite and in augite in the meteorite from Busti, India. It is supposed to be a sulphide, or an oxysulphide, of calcium and probably titanium. Named after Mr. George Osborne

### 65. PENTLANDITE. Eisen-Nickelkies *Scheerer*, Pogg., **58**, 315, 1843. Pentlandite *Dufr*, Min., **2**, 549, 1856. Nicopyrite *Shep.*, Min., 307, 1857. Lillhammerit *Weisbach*, Synops. Min., 57, 1875.

Isometric. Massive, in granular aggregates.

Cleavage octahedral. Fracture uneven. Brittle. H. = 3·5–4. G. = 4·60. Luster metallic. Color light bronze-yellow. Streak light bronze-brown. Opaque. Not magnetic.

**Comp.**—A sulphide of iron and nickel, $(Fe,Ni)S$. In part, $2FeS.NiS$ = Sulphur 36·0, iron 42·0, nickel 22·0 = 100.

**Anal.**—1, 2, Scheerer, l. c. 3, J. K. Mackenzie, priv. contr.

| | S | Fe | Ni | Cu | |
|---|---|---|---|---|---|
| 1. Lillehammer | 36·45 | 42·70 | 18·35 | 1·16 = | 98·66 |
| 2. " | 36·64 | 40·21 | 21·07 | 1·78 = | 99·70 |
| 3. Sudbury | 34·25 | 25·81 | 39·85* | 0·24 = | 100·15 |

* With Co tr

An analysis of the Sudbury nickel ore by Clarke and Catlett gave: S 40·80, Fe 15·57, Ni 41·96, Cu 0·62, $SiO_2$ 1·02 = 99·97, G. = 4·541; this corresponds to $Ni_3FeS_5$, or the general formula of polydymite (p. 75), Am. J. Sc., **37**, 372, 1889. Cf. also pyrrhotite.

**Pyr.**—In the open tube sulphurous fumes. The powdered mineral roasted on charcoal gives with the fluxes reactions for nickel and iron.

**Obs.**—Occurs with chalcopyrite in a hornblende rock near Lillehammer in southern Norway. The mineral from Sudbury, Ontario, (anal. 3) is mined extensively for nickel; it carries a little platinum (0·006 to 0·024 p. c.) probably as sperrylite, Clarke and Catlett. Pentlandite was named after Mr. Pentland.

The Sudbury mineral, examined by Penfield (priv. contr.), shows distinct octahedral cleavage (or parting) which identifies it with the original pentlandite.

---

### 4. Cinnabar-Wurtzite-Millerite Group. Rhombohedral or Hexagonal.

| | | | | | |
|---|---|---|---|---|---|
| | | | | $\dot{c}$ | |
| 66. | **Cinnabar** | HgS | Trapezohedral | 1·1453 | |
| 67. | **Covellite** | CuS | | 1·1466 | |
| | | | | $\dot{c}$ | $\dot{c}$ |
| 68. | **Greenockite** | CdS | Hemimorphic | 0·8109 | or 0·9364 |
| 69. | **Wurtzite** | ZnS | " | 0·8175 | 0·9440 |
| 70. | **Millerite** | NiS | | | 0·9883 |
| 71. | **Niccolite** | NiAs | | 0·8194 | 0·9462 |
| 72. | **Breithauptite** | NiSb | | 0·8586 | 0·9915 |
| | Arite | Ni(Sb,As) | | | |
| 73. | **Troilite** | FeS | | | |
| 74. | **Pyrrhotite** | $Fe_{11}S_{12}$, etc. | | 0·8701 | 1·0047 |

If, as suggested by Groth, the prominent pyramids of wurtzite, greenockite, etc., be made pyramids of the second series (e.g., $x = 11\bar{2}2$, instead of $10\bar{1}1$), then the values of $\dot{c}$ in the second column are obtained, which correspond to millerite. The form of several of these species, however, is only imperfectly known. A rhombohedral form for greenockite has been suggested but not proved.

**66. CINNABAR.** Κιννάβαρις (fr. Spain) *Theophr.* Ἄμμιον *Dioscor.* Minium *Vitruv.*, *Plin.* Minium nativum, *Germ.* Bergzinober, *Agric.*, Interpr., 466, 1546. Cinnabarite. Zinnober, Schwefelquecksilber, Merkur-Blende *Germ.* Cinnober *Swed.* Cinabre *Fr.* Cinabro *Ital.* Cinabrio *Span.*

Rhombohedral; trapezohedral like quartz. Axis $\dot{c} = 1\cdot14526$; $0001 \wedge 10\bar{1}1 = {}^{*}52° 54' 15''$ Schabus[1].

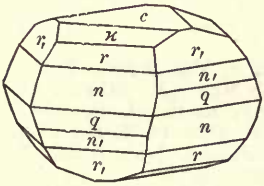
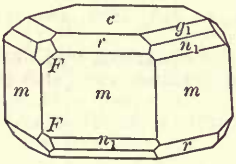
Twins: tw. axis ċ, often penetration-twins[5]; with also tw. pl. *a*, sometimes like the "Brazil twins" of quartz[6]. Crystals usually rhombohedral or thick tabular in habit, rarely showing trapezohedral planes; also acicular prismatic. In crystalline incrustations, granular, massive; sometimes as an earthy coating.

1.



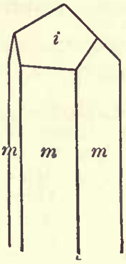
Almaden ?, Sbs.

2.



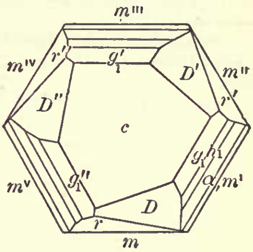
Mt. Avala, Schmidt.

3.



California.

4.



Mt. Avala, Schmidt.

Cleavage: *m* perfect. Fracture subconchoidal, uneven. Somewhat sectile. H. = 2–2·5. G. = 8·0–8·2; 8·090 G. E. Moore. Luster adamantine, inclining to metallic when dark colored, and to dull in friable varieties. Color cochineal-red, often inclining to brownish red and lead-gray. Streak scarlet. Transparent to opaque. Optically +. Indices: $\omega_r = 2{\cdot}854$, $\epsilon_r = 3{\cdot}201$, Dx[8]. Polarization circular, chiefly left handed; twins sometimes showing Airy's spirals[5].

**Var.**—1. *Ordinary:* either (*a*) *crystallized;* (*b*) *massive*, granular embedded or compact; bright red to reddish brown in color; (*c*) *earthy* and bright red.

2. *Hepatic.* Quecksilberlebererz and Quecksilberbranderz, *Germ.* Inflammable cinnabar. Of a liver-brown color, with sometimes a brownish streak, occasionally slaty in structure, though commonly granular or compact. Cinnabar mixed with an organic substance called *idrialine* (q.v.) occurs at Idria. The *corallinerz* of Idria is a curved lamellar variety of hepatic cinnabar.

**Comp.**—Mercuric sulphide, HgS = Sulphur 13·8, mercury 86·2 = 100. Usually impure from the admixture of clay, iron oxide, bitumen.

**Pyr.**—In the closed tube alone a black sublimate of mercuric sulphide, but with sodium carbonate one of metallic mercury. Carefully heated in the open tube gives sulphurous fumes and metallic mercury, which condenses in minute globules on the cold walls of the tube. B.B. on charcoal wholly volatile, but only when quite free from gangue.

**Obs.**—Occurs chiefly in veins in slate rocks and shales, and rarely in granite or porphyry[9]. It has been observed in veins, with ores of iron. The Idria mines are in the Carboniferous formation; those of New Almaden, California, in partially altered Cretaceous or Tertiary beds. It sometimes occurs in connection with hot springs as the result of solfataric action. Pyrite and marcasite, sulphides of copper, stibnite, realgar, gold, etc., are associated minerals; calcite quartz or opal, also barite, fluorite, are gangue minerals; a bituminous mineral (cf. napalite) is common.

The most important European deposits are at Almaden in Spain, and at Idria in Carniola, where it is usually massive. Considerable amounts are now obtained at Bakhmut in southern Russia, where it occurs as an impregnation of a bed of Carboniferous sandstone from 14 to 17 feet in thickness. Good crystals occur in the coal formations of Moschellandsberg and Wolfstein in the Palatinate. Also found at Reichenau in Upper Carinthia; in graywacke at Windisch Kappel; in beds traversing gneiss at Dunbrawa in Transylvania; in fine crystals at the recently reopened mines of Mt. Avala, near Belgrade, Servia; at Neumarktel in Carniola; at Ripa in Tuscany; at Schemnitz in Hungary. In the Urals and the Nerchinsk region in Transbaikal. At the mines of Kwei Chaw in China abundantly, and in Japan. In Guadalcazar, Huitzuco, San

Onofre and elsewhere in Mexico; at Huancavelica in southern Peru, abundant; in the provinces of Coquimbo and Copiapo in Chili. Also in New South Wales, New Zealand, and Transvaal, S. Africa.

In the U. S. forms extensive mines in California, in the Coast Ranges at many different points from Clear Lake in the north (near which there is a vein in a bed of sulphur) to Santa Barbara Co. in the south; important mines are at New Almaden and the vicinity, in Santa Clara Co., about 60 m. S.S.E. of San Francisco. It is now forming by solfataric action at Sulphur Bank, Cal., and Steamboat Springs, Nevada. Also occurs in southern Utah; in Idaho, but only as rolled masses. In Douglas Co., Oregon. In British Columbia, sparsely disseminated through a crystalline limestone at the Ebenezer Mine, Hector (Kicking Horse) Pass, Rocky Mts.

The name cinnabar is supposed to come from India, where it is applied to the red resin, dragon's blood. The native cinnabar of Theophrastus is true cinnabar; he speaks of its affording quicksilver. The Latin name of cinnabar, *minium*, is now given to *red lead*, a substance which was early used for adulterating cinnabar, and so got at last the name. It has been said (King on Precious Stones) that the word *mine* (miniera, *Ital.*) and *mineral* come from the Latin for quicksilver mine, *miniaria* (Fodina miniaria).

**Alt.**—Pseudomorphs after pyrite, tetrahedrite, dolomite have been described (Blum, Pseud., Nachtr., **2**, 123, 124, **3**, 262); also after stibnite (Sandb.). Heated nearly to the point of sublimation and suddenly cooled cinnabar is changed to the black sulphide, HgS; cf. metacinnabarite.

**Art.**—St. Claire Deville and Debray have obtained rhombohedral crystals of cinnabar by sublimation, see Fouqué-Lévy, Synth. Min., p. 313, 1882; also Weinschenk, Zs. Kr., **17**, 498, 1890.

**Ref.**—[1] Ber. Ak. Wien, **6**, 63, 1851; angles confirmed by Koksharov, Min. Russl., **6**, 257, 1870. [2] See Sbs., l. c. for early literature, new planes, etc.; also later Mgg., Jb. Min., **2**, 29, 1882. The distinction between + and − forms is not always surely made, cf. Schmidt[6]. [3] D'Achiardi, as a trigonal prism, tetartohedral, Ripa, Tuscany, Boll. Com. G., **2**, 163, 1871. Min. Tosc., **2**, 282, 1873. [4] Mgg., Almaden, Spain, l. c. [5] Tsch., Nikitovka, Min. Mitth., **7**, 361, 1886. [6] A. Schmidt, Mt. Avala, Servia, Földt. Közl., **17**, 555, 1887, and Zs. Kr., **13**, 433, 1887; no attempt is made to distinguish between + and − rhombohedrons, nor between *r* and *l* trapezohedrons. [7] Traube, Mt. Avala, Zs. Kr., **14**, 563, 1888. [8] Propr. Opt., **1**, 77, 1857.

[9] On the genesis of cinnabar deposits, see Phillips, Q. J. G. Soc., 1879; Christy, Am. J. Sc., **17**, 453, 1879; also LeConte, ib., **24**, 23, 1882; **25**, 424, **26**, 1, 1883; Becker., ib., **33**, 199, 1887, and Mon., **13**, U. S. G. Surv., 1888. In the latter there is given a full description of the occurrence of cinnabar, especially in California and also throughout the world. Becker concludes that the cinnabar, pyrite and gold of the quicksilver mines of the Pacific Slope reached their present position in hot solutions of double sulphides leached from the adjacent granite or the masses underlying it (p. 449).

ETHIOPSITE *Adam*, Tabl. Min., 59, 1869. Black mercurous sulphide, $Hg_2S$; it is an unstable compound, not known to occur in nature.

**67. COVELLITE.** *Freiesleben*, Geogn. Arb., **3**, 129 (fr. Sangerhausen); Kupferindig *Breith.*, in Hoffm. Min., **4**, 2, 178, 1817. A.*

Hexagonal or rhombohedral. Axis $\dot{c} = 1·1466$; $0001 \wedge 10\bar{1}1 = 52° 56\frac{1}{6}'$ Kenngott[1].

**Forms:** *c* (0001, *O*), *a* ($11\bar{2}0$, *i*-2), *x* ($11\bar{2}2$, 1-2), *y* ($22\bar{4}1$, 4-2).

Angles: $cx = 48° 54'$, $cy = 77° 42'$, $xx' = 44° 16\frac{1}{2}'$, $yy' = 58° 29'$, $yy^{vi} = {}^*24° 36'$.

Rarely in hexagonal crystals with faces *m* and *x* horizontally striated. Commonly massive or spheroidal; surface, sometimes crystalline.

Cleavage: basal, perfect. Flexible in thin leaves. H. = 1·5–2. G. = 4·590, 4·636 crystals, Zeph. Luster of crystals submetallic, inclining to resinous, a little pearly on cleavage-face; subresinous or dull when massive. Color indigo-blue or darker. Streak lead-gray to black, shining. Opaque.

**Comp.**—Cupric sulphide, CuS = Sulphur 33·6, copper 66·4 = 100. Analyses, 5th Ed., p. 84.

**Pyr.**—In the closed tube gives a sublimate of sulphur; in the open tube sulphurous fumes. B.B. on charcoal burns with a blue flame, emitting the odor of sulphur, and fuses to a globule, which reacts like chalcocite.

**Obs.**—With other copper ores near Badenweiler in Baden; at Leogang in Salzburg with chalcopyrite, sometimes in small crystals; at Kielce in Poland; Sangerhausen in Saxony; Mansfeld, Thuringia; Vesuvius, on lava; common in Chili.

Named after N. Covelli (1790–1829), the discoverer of the Vesuvian covellite.

Covellite is a result of the alteration of other ores of copper, and is often mixed with chalcocite, from which it has been derived. (See *Digenite* and *Carmenite*, p. 56.)

**Artif.**—Formed at low temperatures (to 200° C.) from CuO, while at higher temperatures, as too from $Cu_2O$, chalcocite ($Cu_2S$) results, Doelter, Zs. Kr., **11**, 34, 1885; also Weinschenk, in crystals, ib., **17**, 497, 1890.

**Ref.**—[1] Leogang, Ber. Ak. Wien, **12**, 22, 1854; the suggestion of Groth as to position is here followed, since it shows the probable relation to cinnabar.

CANTONITE is covellite from the Canton mine, Georgia, occurring in cubes, with a cubical cleavage. It is associated with *harrisite* (pseudomorphs of chalcocite after galena, see p. 56), and is regarded by Genth as a pseudomorph of covellite after the harrisite.

**68. GREENOCKITE.** Greenockite *Jameson*, Ed. N. Phil. J., 28, 390, 1840. Sulphuret of Cadmium *Connel*, ib., 392. Cadmium-Blende. Cadmium sulfuré *Fr.*

Hexagonal; hemimorphic. Axis $\dot{c}$ = 0·81091; 0001 ∧ $10\bar{1}1$ = 43° 7′ 3″ Mügge[1].

**Forms**[1]:

*c* (0001, *O*)
*m* ($10\bar{1}0$, *I*)
*a* ($11\bar{2}0$, *i*-2)
*k* ($21\bar{3}0$, *i*-$\frac{3}{2}$)

*n* ($10\bar{1}7$, $\frac{1}{7}$)
*γ* ($3{\cdot}0{\cdot}\bar{3}{\cdot}20$, $\frac{3}{20}$)
*π* ($10\bar{1}5$, $\frac{1}{5}$)
*i* ($10\bar{1}2$, $\frac{1}{2}$)
*ρ* ($20\bar{2}3$, $\frac{2}{3}$)

*l* ($30\bar{3}4$, $\frac{3}{4}$)
*x* ($10\bar{1}1$, 1)
*p* ($40\bar{4}3$, $\frac{4}{3}$)
*q* ($80\bar{8}5$, $\frac{8}{5}$)
*o* ($50\bar{5}3$, $\frac{5}{3}$)

*y* ($70\bar{7}4$, $\frac{7}{4}$)
*z* ($20\bar{2}1$, 2)
*u* ($30\bar{3}1$, 3)
*w* ($10{\cdot}0{\cdot}\bar{10}{\cdot}3$, $\frac{10}{3}$)
*v* ($40\bar{4}1$, 4)

*r* ($50\bar{5}1$, 5)
*t* (6061, 6)
*s* ($11\bar{2}1$, 2-2)

Of the above forms *γ*, *π*, *ρ* have been observed only at the lower extremity of the crystals. The form of greenockite is near that of the other hemimorphic species, iodyrite and zincite.

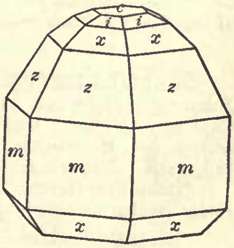
*cn* = 7° 37′
*cγ* = 8° 0′
*cπ* = 10° 36½′
*ci* = 25° 5′
*cρ* = 31° 58½′
*cl* = 35° 5′

*cp* = 51° 18′
*cq* = 56° 17′
*co* = 57° 21′
*cy* = 58° 36′
*cz* = *61° 53′ 55″
*cu* = 70° 24′

*cw* = 72° 14′
*cv* = 75° 3′
*cr* = 77° 56½′
*ct* = 79° 54½′
*cs* = 58° 20½′
*ii*′ = 24° 29′

*xx*′ = 39° 58′
*zz*′ = 52° 20½′
*vv*′ = 57° 46½′
*ss*′ = 50° 23′
*ms* = 42° 30½′
*mx*′ = 70° 1′

Crystals hemimorphic, terminated by *c*, *cx*, or *cγπρx* below, above more complex; the pyramidal faces often striated horizontally, and in oscillatory combination.



Cleavage: *a* distinct, Fdl.; *c* imperfect. Fracture conchoidal. Brittle. H. = 3–3·5. G. = 4·9–5·0. Luster adamantine to resinous. Color honey-, citron- or orange-yellow; also bronze-yellow. Streak-powder between orange-yellow and brick-red. Nearly transparent. Optically +. Double refraction weak. ω = 2·688 Mlr.

**Comp.**—Cadmium sulphide, CdS = Sulphur 22·3, cadmium 77·7 = 100.

**Pyr., etc.**—In the closed tube assumes a carmine-red color while hot, fading to the original yellow on cooling. In the open tube gives sulphurous fumes. B.B. on charcoal, either alone or with soda, gives in R.F. a reddish-brown coating. Soluble in hydrochloric acid, affording hydrogen sulphide.

**Obs.**—Occurs in short hexagonal crystals at Bishopton, in Renfrewshire, Scotland, in a porphyritic trap and amygdaloid, associated with prehnite; also at Bowling near Old Kilpatrick, and at the Boylestone quarry, Barrhead near Glasgow. At Přibram in Bohemia, as a coating especially on sphalerite; similarly elsewhere not uncommon, as at Bleiberg, Carinthia, Pierrefitte, Basses Pyrénées, Laurium, Greece; so too in the U. S. at the Ueberoth zinc mine, near Friedensville, Lehigh Co., Pa., and in the zinc region of southwestern Missouri; in Marion Co., Ark., occurs coloring smithsonite bright yellow.

Named after Lord Greenock (later Earl Cathcart). The first crystal was found about 1810 by Mr. Brown of Lanfyne, and was taken by him for sphalerite. It was over half an inch across.

**Artif.**—Obtained by Hautefeuille in hemimorphic crystals resembling the natural ones, C. R., **93**, 824, 1881. Not an uncommon furnace product.

**Ref.**—[1] Jb. Min., **2**, 18, 1882; for first description of crystals see Breith., Pogg., **51**, 507, 1840: he calls attention to the relations of the group of hexagonal (and rhombohedral) sulphides. Greg and Lettsom, and Mlr. give only *c a m i x z v*. Kk. gave in 1871, $\dot{c}$ = 0·81257, Bull. Acad. St. Pet., **15**, 219; later also $\dot{c}$ = 0·817247, Min. **8**, 125, 1881. Schüler regarded artif. cryst. examined by him as rhombohedral, Lieb. Ann., **87**, 40, 1853.

**69. WURTZITE.** *C. Friedel*, C. R., **52**, 983, 1861. Spiauterit *Breith.*, B. H. Ztg., **21**, 98, 1862, **25**, 193. Faserige Blende, Schalenblende *pt.*

Hexagonal; hemimorphic. Axis $\dot{c} = 0{\cdot}81747$; $0001 \wedge 10\bar{1}1 = 43° \ 20\frac{5}{6}'$ Friedel[1].

**Forms**[1]: *c* (0001, *O*); *m* ($10\bar{1}0$, *I*), *a* ($11\bar{2}0$, *i*-2); *x* ($40\bar{4}5$, $\frac{4}{5}$), *p* ($10\bar{1}1$, 1), *o* (2021, 2).

Angles: *cx* = 37° $3\frac{1}{2}'$, *co* = *62° 5′·4, *xx′* = 35° 4′, *pp′* = 40° 9′, *oo′* = 52° 27′.

Natural crystals quartzoids (*p*) with also *m*, both planes horizontally striated. Also fine fibrous or columnar, massive.

Cleavage: *a* easy; *c* difficult. H. = 3·5–4. G. = 3·98. Luster resinous. Color brownish black. Streak brown. Optically +. Double refraction weak.

**Var.**—1. Crystals, hemimorphic like greenockite. 2. Massive, fibrous, including the varieties of "Schalenblende" having a fine columnar structure (Noelting).

**Comp.**—Zinc sulphide, $ZnS$ = Sulphur 33, zinc 67 = 100.

**Pyr.**—Same as for sphalerite.

**Obs.**—From a silver-mine near Oruro in Bolivia. Also from Albergaria Velha in Portugal; from Quesbesita, Peru, in tabular crystals grouped and forming a crust, some of the crystals $\frac{1}{8}$ inch across. In fine pyramidal crystals with sphalerite and quartz at the "Original Butte" mine, Butte City, Montana.

The massive fibrous forms of "Schalenblende" occur at Přibram, Liskeard, etc. Other forms, from Stolberg, Wiesloch, Altenberg, are in part wurtzite, in part sphalerite.

Named after the French chemist, Adolphe Wurtz.

**Artif.**—First made by St. Claire Deville and Troost by fusing zinc sulphate with $CaF_2$ and BaS in equal parts (C. R., **52**, 920, 1861); also in crystals by a long and high heating of amorphous sphalerite (Sidot, C. R., **62**, 999, 1866); or by subliming the sphalerite in a current of sulphurous oxide, long, transparent, colorless hexagonal prisms have been formed (ib., **63**, 188, 1866). Cf. also Hautefeuille; also Noelting (Inaug. Diss., Kiel, 1887), who traces out the relations of sphalerite and wurtzite, and shows that the latter has often been produced in nature from the former.

**Ref.**—[1] On artif. cryst., C. R., **62**, 1002, 1866; Foerstner obtained $\dot{c} = 0{\cdot}8002$, Zs. Kr., **5**, 363, 1881. [2] On nat. cryst., Bolivia, only *c*, *m*, *a*, *o*, l. c.

Erythrozincite *Damour*, Bull. Soc. Min., **3**, 156, 1880. Probably a manganesian variety of wurtzite. Occurs in thin plates. Optically uniaxial, positive (Dx., ib. **4**, 40, 1881). Soft. Color red. Streak pale yellow. Translucent. Contains sulphur, zinc, manganese. In veins of lapis lazuli from Siberia.

**70. MILLERITE.** Haarkies (as a var. of Schwefelkies) *Wern.*, Bergm. J., 383, 1789 (fr. Johanng.); *Hofmann*, id., 175, 1791. Fer sulfuré capillaire (as a var. of Pyrite) *H.*, Tr., **4**, 1801. Capillary Pyrites. Gediegen Nickel *Klapr.*, Beitr., **5**, 231, 1810. Schwefelnickel *Berz.*; *Arfvedson*, Ak. H. Stockh., 427, 1822. Harkise *Beud.*, Tr., **2**, 400, 1832. Capillose *Chapman*, Min., 135, 1843. Millerit *Haid.*, Handb., 561, 1845. Trichopyrit *Glock.*, Syn., 43, 1847.

Nickelkies *Germ.* Sulphuret of Nickel. Nickel sulfuré *Fr.* Sulfuro di Nickel, Archise *Ital.* Sulfuro de niquel *Span.*

Rhombohedral. Axis $\dot{c} = 0{\cdot}9883$; $0001 \wedge 10\bar{1}1 = 48° \ 46\frac{1}{3}'$ Miller[1].

**Forms**[1]: *m* ($10\bar{1}0$, *I*), *a* ($11\bar{2}0$, *i*-2), *k* ($21\bar{3}0$, *i*-$\frac{3}{2}$); *r* ($10\bar{1}1$, *R*); also as cleavage-faces: *e* ($10\bar{1}6$, $\frac{1}{6}$), *d* ($10\bar{1}3$, $\frac{1}{3}$); *e*, ($01\bar{1}6$, $-\frac{1}{6}$), *d*, ($01\bar{1}3$, $-\frac{1}{3}$).

Angles: *ee′* = 18° $37\frac{1}{2}'$, *dd′* = *35° 52′, *rr′* = 81° 17′, *dd*, = 20° 29′.

Usually in very slender to capillary crystals, often in delicate radiating groups; sometimes interwoven like a wad of hair. Also in columnar tufted coatings, partly semi-globular and radiated.

Cleavage: *e*, *e*,, *d*, *d*,, all perfect, Mlr. Fracture uneven. Brittle; capillary crystals elastic. H. = 3–3·5. G. = 5·3–5·65; 5·65 fr. Saalfeld, Rg. Luster metallic. Color brass-yellow, inclining to bronze-yellow, with often a gray iridescent tarnish. Streak greenish black.

**Comp.**—Nickel sulphide, $NiS$ = Sulphur 35·3, nickel 64·7 = 100.

**Pyr., etc.**—In the open tube sulphurous fumes. B.B. on charcoal fuses to a globule. When roasted, gives with borax and salt of phosphorus a violet bead in O.F., becoming gray in R.F. from reduced metallic nickel. On charcoal in R.F. the roasted mineral gives a coherent metallic mass, attractable by the magnet. Most varieties also show traces of copper, cobalt, and iron with the fluxes.

**Obs.**—Occurs commonly in capillary crystals, in the cavities and among crystals of other minerals. Found at Joachimsthal in Bohemia; Johanngeorgenstadt; Přibram; Riechelsdorf;

Andreasberg; Himmelfahrt mine near Freiberg and Marienberg in Saxony; at Micheroux, Belgium; Cornwall; near Merthyr Tydvil, at Dowlais, occupies cavities in nodules of siderite.

Occurs at the Sterling mine, Antwerp, N. Y., in radiating groups of capillary crystals with ankerite in cavities in hematite; in Lancaster Co., Pa., at Gap mine, with pyrrhotite, in thin coatings of a radiated fibrous structure, often with a velvety surface of crystals, or tufts of radiated needles. With calcite, dolomite and fluorite, forming delicate tangled hair-like tufts, in geodes in limestone, often penetrating the calcite crystals, at St. Louis, Mo.; similarly near Milwaukee, Wis.

Stated to occur in considerable deposits in quartz near Benton in Saline Co., Arkansas (Min. Res. U. S , 128. 1887). Sparingly present with pyrite and marcasite at one of the cinnabar mines in Pope Valley, Mayacmas distr., Cal. With a green chromiferous garnet in Orford Township, Quebec, disseminated in grains in calcite.

Identified in the nickeliferous metallic iron of Santa Catarina, Brazil (Meunier).

**Artif.**—Obtained in groups of acicular crystals by Weinschenk, Zs. Kr , **17**, 500, 1890; also earlier by Baubigny, Fouqué-Lévy, Synth. Min., 306, 1882.

The *capillary pyrites, Haarkies,* of Werner was true millerite, from Johanngeorgenstadt, according to Hofmann, Min., **4**, 168, 1817. But capillary pyrite and marcasite have sometimes gone by the same name.

**Ref.**—[1] Phil. Mag , **6**, 104, 1835, or Pogg., **36**, 476, 1835, and Min., p. 163, 1852. Cf. Breith., Pogg., **51**, 511, 1840.

JAIPURITE. Sulphuret of Cobalt *Middleton,* Phil. Mag., **28**, 352, 1846. Syepoorite *J. Nicoll,* Min., 458, 1849. Jeypoorite *Ross,* Proc. Roy. Soc., **21**, 292, 1873. Jaipurite *F R. Mallet,* Records Geol. Surv. India, **14**, pt. 2, 190, 1880, and Min. India, 16, 1887. Ruténite *Adam,* Tabl. Min., 55, 1869. Kobaltsulfuret pt., Schwefelkobalt pt., Kobaltkies pt., Graukobalterz, Kobaltblende *Germ.*

Described as a simple cobalt sulphide (CoS), occurring massive, with G. = 5·45, and of a steel-gray color, stated to have been found at the Khetri mines, Jaipur (Syepoore, Jeypoor), Rájputána, India, and to be "used by Indian jewelers for staining gold of a delicate rose color." Mallet (l. c.) questions the existence of the mineral, he having found only cobaltite and danaite at the locality. Moreover the cobalt ore from the Khetri mines, sold to Indian enamelers under the name of "sehta," is used in enameling in different shades of blue (not red) on gold and silver.

It is to be noted here that Weinschenk describes an artificial cobalt monosulphide, CoS, in tin-white crystals resembling those obtained of the nickel sulphide, millerite. See Zs. Kr., **17**, 500, 1890.

**71. NICCOLITE.** Kupfernickel *Hiärne,* Anledn. Malm og Berg., 76, 1694. Cuprum Nicolai [mistaken trl.] *J. Woodward,* Foss., 1728. Kupfernickel, Arsenicum sulphure et cupro mineralisatum, aeris modo rubente, *Wall.*, 228, 1747. Niccolum ferro et cobalto arsenicatis et sulphuratis min. (fr. Saxony) *Cronst.* Ak. H. Hexagonal. Axis $\dot{c} = 0{\cdot}8194$; $0001 \wedge 10\bar{1}1 = {}^*43° 25'$ Breithaupt[1].

**Forms:** $c$ (0001, $O$), $m$ ($10\bar{1}0$, $I$); $x$ ($10\bar{1}1$, 1). Angle: $xx' = 40° 12'$.

Crystals rare. Usually massive, structure nearly impalpable; also reniform with a columnar structure; also reticulated and arborescent.

Fracture uneven. Brittle. H. = 5–5·5. G. = 7·33–7·67. Luster metallic. Color pale copper-red, with a gray to blackish tarnish. Streak pale brownish black. Opaque.

**Comp.**—Nickel arsenide, NiAs = Arsenic 56·1, nickel 43·9 = 100. Usually contains a little iron and cobalt, also sulphur; sometimes part of the arsenic is replaced by antimony, and then it graduates toward breithauptite. The intermediate varieties have been called *arite.*

**Anal.**—1, Petersen, Pogg., **134**, 82, 1868. 2, Winkler, Jb. Min., 818, 1872. 3, L. Sipöcz, Zs. Kr., **11**, 215, 1885. 4, Genth, Am Phil. Soc., **20**, 403, 1882. 5–7, Berthier, Ann. Mines, **4**, 467, 1819; ibid., **7**, 537, 1835. 8, Petersen, Pogg., **137**, 396, 1869. 9, Pisani, l. c.

**Pyr., etc.**—In the closed tube a faint white crystalline sublimate of arsenic trioxide. In the open tube a sublimate of arsenic trioxide, with a trace of sulphurous fumes, the assay becoming yellowish green. On charcoal gives arsenical fumes and fuses to a globule, which, treated with borax glass, affords, by successive oxidation, reactions for iron, cobalt, and nickel; the antimonial varieties give also reactions for antimony. Soluble in aqua regia.

**Obs.**—Accompanies cobalt, silver, and copper in the Saxon mines of Annaberg, Schneeberg, etc.; also in Thuringia, Hesse, and Styria, and at Allemont in Dauphiné; at the Ko mines in Nordmark, Sweden; at Balen in the Basses Pyrénées (*arite*); occasionally in Cornwall, as at Pengelly and Wheal Chance; formerly at the Hilderstone Hills, Scotland; at Chañarcillo, near Copiapo, and at Huasco, Chili; abundant at Mina de la Rioja, Oriocha, in the Argentine Republic.

Found at Chatham, Conn., in gneiss, associated with smaltite; sparingly at Franklin Furnace, N. J. (Koenig); Silver Cliff, Colorado; Tilt Cove, Newfoundland.

Named from the contained metal. The name of the species should be formed from the Latin word for nickel, *niccolum*, proposed by Cronstedt, and hence should be written *niccoline*, or better *niccolite*, in place of Beudant's *nickeline*.

**Ref.**—[1] L. c., Pogg., **51**, 515, 1840.

**72. BREITHAUPTITE.** Antimonnickel *Stromeyer & Hausm.*, Gel. Anz. Gött., 2001, 1833. Antimonial Nickel. Hartmannite *Chapman*, Min., 1843. Breithauptit *Haid.*, Handb., 559, 1845.

Hexagonal: Axis $\dot{c} = 0{\cdot}8586$; $0001 \wedge 10\bar{1}1 = 44° 45\frac{1}{6}'$ Breithaupt[1].

**Forms:** *c* (0001, *O*), *m* ($10\bar{1}0$, *I*); *i* ($10\bar{1}2$, $\frac{1}{2}$), *w* ($30\bar{3}2$, $\frac{3}{2}$), *v* ($20\bar{2}1$, 2)[2].

Angles: *ci* = 26° 22′, *cw* = *56° 5′, *cv* = 63° 14′, *ii′* = 25° 40′, *ww′* = 49° 2′.

Crystals thin tabular, rare; also hexagonal prisms (artif.[2]). Arborescent and disseminated, massive.

Fracture uneven to small subconchoidal. Brittle. H. = 5·5. G. = 7·541 Breith. Luster metallic, splendent. Color on the fresh fracture light copper-red, inclining strongly to violet. Streak reddish brown. Opaque.

**Comp.**—Nickel antimonide, NiSb = Antimony 67·2, nickel 32·8 = 100. Arsenic is sometimes present; compare analyses 5–9 under niccolite.

**Pyr.**—In the open tube white antimonial fumes. On charcoal fuses in R.F.; gives off antimonial fumes, and coats the coal white; if lead is present, a yellow coating near the assay; treated with soda the odor of arsenic may be distinguished in most specimens.

**Obs.**—Found in the Harz at Andreasberg, with calcite, galena, and smaltite. Has been observed as a furnace product, crystallized, cf. ref.[2] below.

Named after the Saxon mineralogist, J. F. A. Breithaupt (1791–1873).

**Ref.**—[1] Pogg., **51**, 512, 1840. [2] Brand, on artif. cryst., Zs. Kr., **12**, 234, 1886.

**73. TROILITE.** Pyrrhotite pt. Troilit *Haid.*, Ber. Ak. Wien, **47** (2), 283, 1863.

Usually massive.

H. = 4·0. G. = 4·75–4·82. Color tomback-brown. Streak black.

**Comp.**—Iron sulphide, usually accepted as FeS = Sulphur 36·4, iron 63·6 = 100; it may, however, be identical with pyrrhotite, as urged by Meunier.

**Anal.**—1, J. L. Smith, Am. J. Sc., **19**, 156, 1855. 2, Id., C. R., **81**, 976, 1875, also Rg., l. c. 3, Rg., Min. Ch., 53, 1875, cf. also Pogg., **74**, 443, 1848, **122**, 365, 1864. 4, E. Geinitz, Jb. Min., 608, 1876. 5, 6, Meunier, Ann. Ch. Phys., **17**, 36, 1869.

**Pyr.**, etc.—Same as for pyrrhotite.

**Obs.**—Common in iron meteorites in nodules disseminated more or less sparingly through the mass, also in narrow veins usually separated from the iron by a thin layer of graphite.

It is assumed by Rose that the iron sulphide of meteoric iron is troilite, that of meteoric stones (sometimes crystallized) is pyrrhotite, but as remarked above, they may be both pyrrhotite.

Named after Dominico Troili, who, in 1766, described a meteorite that fell that year at Albareto in Modena, which contains this species.

**Artif.**—The simple iron monosulphide is a common laboratory product. Weinschenk has obtained it in crystals, small hexagonal tables, showing the basal plane and pyramids (or rhombohedrons), Zs. Kr., **17**, 499, 1890.

**74. PYRRHOTITE.** Vattenkies, Pyrites fusca, Minera hepatica, pt., *Wall.*, Min., 209, 212, 1747. Pyrites en prismes hexagonales *Forst.*, Cat., 1772; *Bourn.*, de Lisle's Crist., **3**, 243, 1783. Hexagonal. Axis $\dot{c} = 0·8701$; $0001 \wedge 10\bar{1}1 = 45° \ 7\tfrac{5}{6}'$ Rose[1].

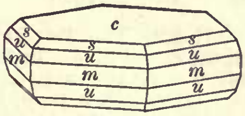
**Forms**[2]: *c* (0001, *O*), *m* ($10\bar{1}0$, *I*), *a* ($11\bar{2}0$, *i*-2), *s* ($10\bar{1}1$, 1), *z* ($20\bar{2}1$, 2), *u* ($40\bar{4}1$, 4), *w* ($60\bar{6}1$, 6)[3]? *y* ($20·0·\overline{20}·3$, $\tfrac{20}{3}$)[4]; *v* ($11\bar{2}1$, 2-2).

*cs* = 45° 8′ *cw* = 80° 35′ *ss′* = 41° 30½′ *vv′* = 51° 22′
*cz* = 63° 32′ *cy* = 81° 30½′ *zz′* = *53° 11′ *av* = 41° 20′
*cu* = 76° 0′ *cv* = 60° 7′ *uu′* = 58° 3′ *ms′* = 69° 15′

Twins: tw. pl. *s*, with vertical axes nearly at right angles (f. 2). Distinct crystals rare, commonly tabular; also acute pyramidal with faces striated horizontally. Usually massive, with granular structure.

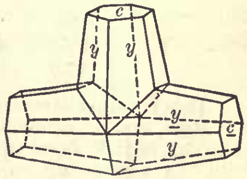
Parting: *c* sometimes distinct; *a* less so. Fracture uneven to subconchoidal. Brittle. H. = 3·5–4·5. G. = 4·58–4·64. Luster metallic. Color between bronze-yellow and copper-red, and subject to speedy tarnish. Streak dark grayish black. Magnetic, but varying much in intensity; sometimes possessing polarity.

1.



Cyclopean Is., Slg.

2.



Elizabethtown[4].

**Comp.**—A sulphide of iron, often containing also nickel; formula chiefly $Fe_{11}S_{12}$, which is also the composition of the artificial compound (Doelter). Analyses, however, vary from $Fe_5S_6$ up to $Fe_{16}S_{17}$, while conforming to the general formula $Fe_nS_{n+1}$. Percentage composition $Fe_{11}S_{12}$ = Sulphur 38·4, iron 61·6 = 100; $Fe_7S_8$ = Sulphur 39·6, iron 60·4 = 100; $Fe_8S_9$ = Sulphur 39·2, iron 60·8 = 100.

The analyses collected and tabulated by Lindström, and later with additions by Habermehl, show a variation from Fe : S = 1 : 1·1902, corresponding to $Fe_5S_6$, to 1 : 1·0610 or $Fe_{16}S_{17}$. The material may not in all cases have been homogeneous. Habermehl obtained from the Bodenmais pyrrhotite, Fe = 60·57, as the mean of 14 determinations, ten of them essentially identical, on portions separated successively from the fine powder suspended in water by a strong magnet; the material was thus proved to be homogeneous and to conform closely to $Fe_7S_8$. On the other hand Bodewig and also Doelter have obtained $Fe_{11}S_{12}$. The FeS of anal. 4 needs confirmation.

For a discussion of the composition see Rg., Pogg., **121**, 337, 1864; Lindström, Öfv. Ak. Stockh., **32**, No. 2, 25, 1875; Habermehl, Ber. Oberhess. Ges., **18**, 83, 1879; Bodewig, Zs. Kr., **7**, 174, 1882; Doelter, Min. Mitth., **7**, 535, 1886.

Forbes (Phil. Mag., **35**, 174, 180, 1868) has described a sulphide of iron and nickel from Scotland, which seems to lie between pyrrhotite and pentlandite. Massive, strongly magnetic. Occurs near Inverary Castle, Argyleshire, anal. 1, after deducting impurities; also from the Craigmuir mine, eight miles below Inverary, anal. 2. In both the ratio of Fe : Ni = 5 : 1 nearly.

| | G. | S | Fe | Ni | |
|---|---|---|---|---|---|
| 1. | 4·50 | 38·01 | 50·66 | 11·33 | Co, Cu *tr.* = 100 |
| 2. | 4·60 | 37·99 | 50·87 | 10·01 | Co 1·02, As 0·04, Cu *tr.* = 99·93 |

This is called *inverarite* by Heddle, Enc. Brit., **16**, 392, 1883.

**Pyr., etc.**—Unchanged in the closed tube. In the open tube gives sulphurous fumes. On charcoal in R.F. fuses to a black magnetic mass; in O.F. is converted into red oxide, which with fluxes gives only an iron reaction when pure, but many varieties yield small amounts of nickel and cobalt. Decomposed by hydrochloric acid, with evolution of hydrogen sulphide.

**Obs.**—Occurs at Kongsberg, Modum, Snarum, Hilsen, in Norway; Klefva and Fahlun in Sweden; Andreasberg and Treseburg, Harz; Bodenmais in Bavaria; Breitenbrunn, Saxony; Joachimsthal, Bohemia; Nizhni Tagilsk; Minas Geraes in Brazil, in large tabular crystals; the lavas of Vesuvius; Cornwall; Appin in Argyleshire.

In N. America in *Maine*, at Standish in crystals with andalusite; in *Vermont*, at Stafford, Corinth, and Shrewsbury. In many parts of *Massachusetts*. In *Connecticut*, at Trumbull with topaz, in Monroe, and elsewhere. In *N. York*, 1½ m. N. of Port Henry, Essex Co.; near Natural Bridge in Diana, Lewis Co.; at O'Neil mine and elsewhere in Orange Co. In *N. Jersey*, Morris Co., at Hurdstown, cleavable massive. In *Pennsylvania*, at the Gap mine, Lancaster Co., niccoliferous. In *Tennessee*, at Ducktown mines, abundant. In Canada, in large veins at St. Jérôme, Elizabethtown, Ontario; at Sudbury (anal. 17), etc.

Pyrrhotite is often present in disseminated particles or crystals in meteoric stones; the iron sulphide of meteoric irons (p. 29) is generally referred to troilite (Rose, l. c., cf. troilite).

Named from *πυῤῥότης, reddish.*

**Alt.**—Occurs altered to pyrite (G. Rose, ZS. G. Ges., **10**, 98, 1858); also to limonite and siderite.

**Ref.**—[1] Crystals from the Juvinas meteorite, which fell June 15, 1821, Pogg., **4**, 180, 1825. Other determinations: Kenng., Kongsberg, $zz' = 53° 22'$, Ber. Ak. Wien, **9**, 1852; Slg., Cyclopean Is. on analcite, $cu = 75° 18'$ and $uu' = 57° 51'$, whence $\dot{c} = 1·6502$, Zs. Kr., **11**, 343, 1886 An orthorhombic form for pyrrhotite has been suggested but not confirmed, cf. Streng. Jb. Min., 799, 1878, **1**, 183, 1882.

[2] Rose observed *c, a, m, s, z, v*; Bournon early gave figures and measurements from which Rose deduces 2021 and 1122 (cf. Ph., Min., 213, 1837). Slg. gives *c, m, s, u.* [3] D'Achiardi, Bottino, Att. Soc. Tosc., **2**, 114, 1876. [4] E. S. D., Elizabethtown, Ontario, Am. J. Sc., **11**, 386, 1876; *w* and *y* may be identical, the measured angles given are 80½° and 81½° respectively.

KRŒBERITE *D. Forbes*, Phil. Mag., **29**, 9, 1865. Krœberite is a strongly magnetic mineral, in copper-colored crystals, not yet analyzed, which Forbes says "appears to be principally a subsulphide of iron." The reasons for this opinion are not stated. Named after P. Krœber. It is from between La Paz and Yungas, on the eastern slope of the Andes.

HORBACHITE, *Knop*, Jb. Min., 521, 1873. In crystalline masses, showing an imperfect cleavage direction. H. = 4·5. G. = 4·43. Color resembling pyrrhotite but darker, pinchbeck-brown to steel-gray. Streak black. Analysis, Wagner, l. c.

S $\frac{4}{4}$ 45·87 Fe 41·96 Ni 11·98 = 99·81

This corresponds pretty nearly to $4Fe_2S_3.Ni_2S_3$. If confirmed, it would belong in the following section. An earlier analysis by Rg. gave different results, viz.: S 40·03, Fe 55·96, Ni 3·86 = 99·85, G. = 4·7; the latter called it simply pyrrhotite. Pogg., **121**, 361, 1864.

Decomposed rather easily under the influence of air and water, forming iron and nickel vitriol. Occurs with chalcopyrite in irregular masses in the serpentinized gneiss at Horbach near St. Blasien, in the Black Forest.

---

## C. Intermediate Division.

### Group 1.

75. **Polydymite** $Ni_4S_5$ Isometric
76. **Beyrichite** $Ni_3S_4$

Polydymite and Beyrichite may prove to be the same species.

77. **Melonite** $Ni_2Te_3$

**75. POLYDYMITE** *H. Laspeyres*, J. pr. Ch., **14**, 397, 1876.

Isometric. In octahedrons; frequently in polysynthetic twins with tw. pl. *o*; often tabular.

Cleavage: cubic, imperfect. H. = 4·5. G. = 4·54–4·81. Luster metallic, brilliant on the fresh fracture. Color light gray to steel-gray; easily tarnished. Opaque.

**Comp.**—A nickel sulphide, perhaps $Ni_4S_5$ = Sulphur 40·6, nickel 59·4 = 100.

**Anal.**—1, 2, Laspeyres, on 0·28 and 0·2 gr.

| | | S | Ni | Co | Fe | Sb | As | | |
|---|---|---|---|---|---|---|---|---|---|
| 1. Grünau | G. = 4·81 | 40·27 | 53·51 | 0·61 | 3·84 | 0·51 | 1·04 | = | 99·78 |
| 2. " | | 39·20 | 53·13 | | 4·12 | 1·15 | 2·30 | = | 99·90 |

After deducting impurities (gersdorffite, ullmannite 5 p. c.), anal. 1 becomes: S 41·09, Ni 54·30, Co 0·63, Fe 3·98 = 100.

**Pyr., etc.**—Insoluble in hydrochloric, soluble in nitric, acid, with separation of sulphur. B.B. decrepitates, in the closed tube gives a sulphur sublimate and fuses to a dark-green magnetic bead.

**Obs.**—Occurs intimately mixed with gersdorffite, ullmannite, millerite, siderite, quartz, sphalerite, galena, bismuthinite, and other minerals, at Grünau, in Sayn-Altenkirchen, Westphalia.

A nickel ore from Sudbury, Ontario, analyzed by Clarke and Catlett (Am. J. Sc., **37**, 372, 1889, cf. p. 65) corresponds to $Ni_3FeS_5$, conforming to the general formula of polydymite; another Sudbury ore agrees with pentlandite (cf. p. 65), and still another is a nickeliferous pyrrhotite (p. 74).

Named from πολύς *many*, δίδυμος *twin*, because observed in polysynthetic twinned forms.

GRÜNAUITE. Nickelwismuthglanz *Kbl*, J. pr. Ch., **6**, 332, 1835. Bismuth Nickel. Grünauite *Nicol.*, Min., 458, 1849. Saynit *Kbl.*, Taf., 13, 1853. Wismuthnickelkies, Wismuthnickelkobaltkies *Germ.*

Described as isometric, with octahedral cleavage. H. = 4·5. G. = 5·13. Luster metallic. Color light steel-gray to silver-white, often tarnished. Streak dark gray. Analyses: 1, Kobell, l. c. 2, 3, Schnabel, Rg., Min. Ch., 108, 1860.

| | S | Bi | Ni | Fe | Co | Cu | Pb | | |
|---|---|---|---|---|---|---|---|---|---|
| 1. | 38·46 | 14·11 | 40·65 | 3·48 | 0·28 | 1·68 | 1·58 | = | 100·24 |
| 2. | 31·99 | 10·49 | 22·03 | 5·55 | 11·24 | 11·59 | 7·11 | = | 100 |
| 3. | 33·10 | 10·41 | 22·78 | 6·06 | 11·73 | 11·56 | 4·36 | = | 100 |

Found at Grünau, in Sayn-Altenkirchen, with quartz and chalcopyrite. According to Laspeyres this supposed species is a polydymite, impure through the admixture of bismuthinite, also chalcopyrite, and galena.

**76. BEYRICHITE.** *Ferber; K. Th. Liebe*, Jb. Min., 840, 1871.

In complex prismatic crystals longitudinally striated, grouped radially or twisted screw-like. Terminated by a single plane (cleavage) with another plane inclined 81° to vertical axis, and a third 36° to this.

H. = 3–3·5. G. = 4·7. Luster metallic. Color lead-gray.

**Comp.**—Perhaps $Ni_3S_4$ or $2NiS.NiS_2$ = Sulphur 42·1, nickel 57·9 = 100.

**Analysis.**—Liebe, l. c.

S 42·86 Fe 2·79 Ni 54·23 = 99·88

**Pyr., etc.**—B.B. in the closed tube decrepitates and gives a sublimate of sulphur, on charcoal fuses to a brass-yellow magnetic globule. Soluble in aqua regia, yielding an emerald-green solution.

**Obs.**—From Lommerichskaul mine in Westerwald, where it is associated with millerite, and into which it is believed to change readily.

**Artif.**—An artificial nickel sulphide, having the composition $Ni_3S_4$, has been obtained by Sénarmont, Ann. Ch. Phys., **32**, 165, 1851.

**77. MELONITE.** *Genth*, Am. J. Sc., **45**, 313, 1868. Tellurnickel *Rg.*, Min. Ch., 17, 1875.

Hexagonal, with eminent basal cleavage. Generally in indistinct granular and foliated particles.

Luster metallic. Color reddish white, rarely tarnished brown. Streak dark gray.

**Comp.**—A nickel telluride, perhaps $Ni_2Te_3$ = Tellurium 76·2, nickel 23·8 = 100.

**Anal.**—Genth, l. c., after deducting 22·2 p. c. quartz and 3·26 gold:

Te 73·43 Ni 20·98 (Co *tr.*) Ag 4·08 Pb 0·72 = 99·21

Genth considers the analysis to correspond to 6·60 p. c. hessite, 1·17 altaite, 2·29 native tellurium, and 89·25 melonite.

**Pyr., etc.**—B.B. in the open tube gives a sublimate fusing to colorless drops, leaving a gray mass; on charcoal burns with a bluish flame, giving a white volatile coating, and a greenish gray residue; in R.F. with soda a gray powder of magnetic metallic nickel. Soluble in nitric acid, giving a green color, and on evaporation yielding a white crystalline powder of tellurium dioxide.

**Obs.**—Found with other tellurium minerals at the Stanislaus mine, California. Probably also at the Forlorn Hope mine, Boulder Co., Colorado (Hillebrand).

### Group 2.

The species here included are sometimes regarded as Sulpho-salts: Sulphoferrites, etc. Cf. Groth, Tab. Ueb., 25, 1889.

Miners.* Brokig koppar-malm *Swed.* Chalcomiklit *Blomstrand*, Öfv. Ak. Stockh., **27**, 24, 1870.

Isometric. Observed forms:

*a* (100, *i-i*) *d* (110, *i*) *o* (111, 1) *n* (211, 2-2)

Twins: tw. pl. *o*, often penetration-twins, hexagonal in form. Habit cubic, faces often rough or curved. Massive, structure granular or compact.

Cleavage: *o* in traces. Fracture small conchoidal, uneven. Brittle. H. = 3. G. = 4·9–5·4. Luster metallic. Color between copper-red and pinchbeck-brown on fresh fracture, speedily iridescent from tarnish. Streak pale grayish black. Opaque.

**Comp., Var.**—A sulphide of copper and iron, but varying in the proportions of these metals. The crystallized mineral agrees with $Cu_3FeS_3$ = Sulphur 28·1, copper 55·5, iron 16·4 = 100; this may be written $3Cu_2S.Fe_2S_3$ (Groth) or $Cu_2S.CuS.FeS$ (Rg.).

Analyses of massive varieties give from 50 to 70 p. c. of copper and 15 to 6·5 p. c. of iron. The variation is due, in part at least, to mechanical admixture, chiefly of chalcocite; this commonly accepted view has been confirmed by Baumhauer by microscopic examination. Zs. Kr., **10**, 447. 1885.

| 17. Eisleben | | 22·65 | 69·72 | 7·54 | = 99·91 |

Many analyses of the massive mineral, as urged by Cleve, agree closely with $Cu_5FeS_4$ or $5Cu_2S.Fe_2S_3$ = Sulphur 25·5, copper 63·3, iron 11·2. Other analyses deviate more widely from the above formula, cf. 5th Ed., p. 45.

**Pyr., etc.**—In the closed tube gives a faint sublimate of sulphur. In the open tube yields sulphurous fumes, but no sublimate. B.B. on charcoal fuses in R.F. to a brittle magnetic globule. The roasted mineral gives with the fluxes the reactions of iron and copper, and with soda a metallic globule. Soluble in nitric acid with separation of sulphur.

**Obs.**—Occurs with other copper ores, and is a valuable ore of copper. Crystalline varieties are found in Cornwall, and mostly in the mines of Tincroft and Dolcoath near Redruth, where it is called by the miners "horse-flesh ore." Other foreign localities of massive varieties are at Ross Island, Killarney. in Ireland; at Monte Catini, Tuscany; in cupriferous shale in the Mansfeld district, Germany; in the Ardennes; in Norway, Sweden (see above anal. 5 to 15), Siberia, Silesia, and Hungary. It is the principal copper ore at some Chilian mines, especially those of Tamaya and Sapos; also common in Peru, Bolivia, and Mexico.

At the copper mine in Bristol, Conn., abundant, and often in fine crystallizations. At Cheshire, sparingly in cubes, with barite, malachite, and chalcocite. Massive at Mahoopeny, near Wilkesbarre, Penn., and in other parts of the same State, in cupriferous shale, associated in small quantities with chalcocite; also in granite at Chesterfield, Mass.; in New Jersey. A common ore in Canada, at the Acton and other mines, along a belt of 15–20 m., between L. Memphremagog and Quebec. Howe Inlet, Br. Columbia.

Named after Ignatius von Born, a distinguished mineralogist of the last century (1742–1791). The name phillipsite has a prior use for another species.

**Artif.**—Cf. Doelter, Zs. Kr., **11**, 36, 1885.

CASTILLITE *Rg.*, Zs. G. Ges., **18**, 23, 1866. A massive mineral from Guanasevi, Mexico, resembling bornite in color and tarnish. H. = 3. G. = 5·19–5·24. Analysis, Rg.:

S 25·65  Cu 41·11  Zn 12·09  Pb 10·04  Ag 4·64  Fe 6·49 = 100·02

Rammelsberg writes the formula $(Cu,Ag)^2S.2(Cu,Pb,Zn,Fe)S$, but it can hardly be regarded as other than a mixture, probably an impure bornite.

---

**79. LINNÆITE.** Kobolt med Jern och Svafelsyra (fr. Bastnaes) *G. Brandt*, Ak. H. Stockh., 119, 1746. Kobolt med förvswafladt Järn, Cobaltum Ferro Sulphurato mineralisatum, *Cronst.*, 213, 1758. Cobaltum pyriticosum *Linn.*, 1768; *de Born*, Lithoph., **1**, 144, 1772. Mine de Cobalt sulfureuse *de Lisle*, **3**, 134, 1783. Kobalt-Glanz pt. *Wern.*, *Kirwan*, *etc.* Svafelbunden Kobolt *Hisinger*, Afh., **3**, 316, 1810. Kobaltkies *Hausm.*, Handb., 158, 1813. Schwefelkobalt. Sulphuret of Cobalt; Cobalt Pyrites. Cobalt sulfuré *Fr.* Koboldine *Beud.*, Tr., **2**, 417, 1832. Linneit *Haid.*, Handb., 560, 1845. Kobaltnickelkies [not Kobaltkies] *Rg.* Siegenite (fr. Müsen) *Dana*, Min., 687, 1850. Koboltkis *Swed.*

Isometric. Commonly in octahedrons. Twins: tw. pl. octahedral. Also massive, granular to compact.

Cleavage: cubic, imperfect. Fracture uneven to subconchoidal. Brittle. Etching figures similar to those of magnetite[1]. H. = 5·5. G. = 4·8–5. Luster metallic. Color pale steel-gray, tarnishing copper-red. Streak blackish gray.

**Comp., Var.**—A sulphide of cobalt, $Co_3S_4 = CoS.Co_2S_3$ analogous to the spinel group. This requires: Sulphur 42·1, cobalt 57·9 = 100. The cobalt is replaced by nickel and to some extent by iron and copper in very varying proportions.

The niccoliferous variety has been called *siegenite*, Dana, Min., p. 687, 1850. The name *linnæite*, after Linnæus, was given by Haidinger to the Bastnaes mineral.

[a] A portion lost.

Hisinger obtained 14·4 p. c. Cu in the Bastnaes mineral, but it is not certain that it all belonged to the pure linnæite.

**Pyr., etc.**—The variety from Müsen gives, in the closed tube, a sulphur sublimate; in the open tube, sulphurous fumes, with a faint sublimate of arsenic trioxide. B.B. on charcoal gives sulphurous (and arsenical) odors, and fuses to a magnetic globule. The roasted mineral gives with the fluxes reactions for nickel, cobalt, and iron. Soluble in nitric acid, with separation of sulphur.

**Obs.**—In gneiss, with chalcopyrite, at Bastnaes, near Riddarhyttan, Sweden, also at Gladhammar; at Müsen, near Siegen, in Prussia, with barite and siderite; at Siegen (*siegenite*), in octahedrons; at Mine la Motte, in Missouri, mostly massive, sometimes octahedral and cubo-octahedral crystals; and at Mineral Hill, in Maryland, in a vein in chlorite slate, with chalcopyrite, bornite, sphalerite, pyrite, etc.

**Alt.**—Occurs altered to yellow earthy cobalt so-called (*gelb Erdkobalt*), which is a mixture of erythrite and pitticite.

**Ref.**—[1] Becke, Min. Mitth., **7**, 225, 1885.

**80. DAUBREELITE** *J. L. Smith*, Am. J. Sc., **12**, 109, 1876; **16**, 270, 1878.

Massive; somewhat scaly, structure crystalline.

Cleavage in one direction. Brittle. Fracture uneven. G. = 5·01. Luster metallic, brilliant. Color black. Streak black. Not magnetic.

**Comp.**—$FeS.Cr_2S_3$ = Sulphur 44·3, chromium 36·3, iron 19·4 = 100.

**Anal.**—Smith, l. c. $\frac{3}{3}$ S 42·69 Cr 35·91 Fe 20·10 = 98·70

**Pyr.**—B.B. infusible, loses luster and (R.F.) becomes magnetic. With borax reacts for chromium. Not attacked by cold nor by hot hydrochloric acid, but completely dissolved in nitric acid, without the liberation of free sulphur.

**Obs.**—Occurs associated with troilite, on the borders of troilite nodules, or as minute veins running across them, in the meteoric irons from Cohahuila, Mexico. Also identified in the irons of Toluca, Mexico, of Sevier, Tenn., and of Cranbourne, Australia. Named after M. Daubrée, of Paris

The name *schreibersite* was given by Shepard to a supposed chromium sesquisulphide, occurring in the Bishopville meteorite (Am. J. Sc., **2**, 383, 1846). It is not contained in Shepard's list of meteoric minerals (ibid., **43**, 28), published in 1867.

**81. CUBANITE** Weisskupfererz *pt.* Cuban *Breith.*, Pogg., **59**, 325, 1843. Cubanite *Chapman.*

Isometric. Massive.

Cleavage: cubic, and rather more distinct than in ordinary pyrite, Breith. Color between bronze- and brass-yellow. Streak dark reddish bronze, black. H. = 4. G. = 4·026–4·042 Br.; 4·169 Booth.

**Comp.**—$CuFe_2S_4$ = $CuS.Fe_2S_3$ = Sulphur 35·4, copper 23·3, iron 41·3 = 100.

**Anal.**—1, Eastwick, Dana, Min., p. 68, 1854. 2, Magee, ib. 3, Stevens, ib. 4, Scheidhauer, Pogg., **64**, 280, 1845. 5, J. L. Smith, Am. J. Sc., **18**, 381, 1854. 6, 7, 8, Carlin, Brodin, Lindström, G. För. Förh., **1**, 105, 1873.

| 8. Kafveltorp | | 34·62 | 22·69 | 40·71 | Zn 1·11, insol. 0·38 = 99·51 |

**Pyr.**—In the closed tube a sulphur sublimate; in the open tube sulphur dioxide. B.B. on charcoal gives sulphur fumes and fuses to a magnetic globule. The roasted ore reacts for copper and iron with the fluxes; with soda on charcoal gives a globule of metallic iron with copper.

**Obs.**—From Barracanao, Cuba; Tunaberg and Kafveltorp, Sweden.

CHALCOPYRRHOTITE. Chalkopyrrhotin *Blomstrand*, Öfv. Ak. Stockh., **27**, 23, 1870. Massive. Color like that of pyrite with a tinge of brown. H. = 3·5–4. G. = 4·28. Analysis: $\frac{2}{2}$ S 38·16, Fe 48·22, Cu 12·98, residue 0·74 = 100·10, which gives the formula $Fe_4CuS_6$. Occurs at Nya Kopparberg, Sweden, in small imbedded portions with magnetite, sphalerite, calcite, and chondrodite.

A "Weisskupfererz" (cf. p. 96) from Halzbrücke, near Freiberg, gave Frenzel: S 44·83, Fe 40·47, Cu 10·75, Co 2·61 = 98·66. Jb. Min., 785, 1873.

**82. CARROLLITE.** *Faber*, Am. J. Sc., **13**, 418, 1852.

Isometric. Rarely in octahedrons. Massive.

Fracture subconchoidal or uneven. H. = 5·5. G. = 4·85. Luster metallic. Color light steel-gray, with a faint reddish hue.

**Comp.**—A sulphide of copper and cobalt, $CuCo_2S_4$ or $CuS.Co_2S_3$ = Sulphur 41·5, cobalt 38·0, copper 20·5 = 100.

**Anal.**—1–3, Smith and Brush, Am. J. Sc., **16**, 367, 1853. 4, Genth, ib., **23**, 418, 1857.

Twins[8]: (1) tw. pl. *p* (111), comp.-face usually *p*, f. 6, and f. 15 a penetration-twin, also $\perp$ *p*; sometimes repeated as a fiveling, f. 7. (2) Tw. pl. and comp.-face *e*, f. 5, often in repeated twins. (3) Tw. pl. *m*, tw. axis *c*, complementary penetration-twins. Rarely by twinning (f. 13) pseudo-rhombohedral in symmetry.

Crystals commonly tetrahedral in aspect, the sphenoidal faces *p* large, dull in luster or oxidized, and diagonally striated; while *p*, are small, brilliant, not oxidized, not striated; scalenohedral faces often prominent and often striated ‖ intersection with *p*. Sphenoidal and other faces also striated as in figs 8–15 Often massive, compact.

Cleavage: *z*, sometimes distinct; *c*, indistinct. Fracture uneven. Brittle. H. = 3·5–4. G. = 4·1–4·3. Luster metallic. Color brass-yellow; often tarnished or iridescent. Streak greenish black. Opaque.

**Comp.**—A sulphide of copper and iron, $CuFeS_2$ or $Cu_2S.Fe_2S_3$ = Sulphur 35·0, copper 34·5, iron 30·5 = 100. Analyses often show variation from this formula due in most cases certainly to mechanical admixture of pyrite.

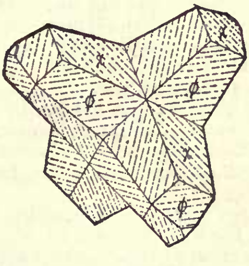
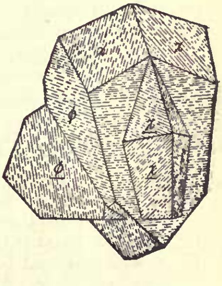
14.



15.



Figs. 8–15, French Creek, Penn., Penfield.

Sometimes auriferous and argentiferous (*Gualda* Span. S. A.). Traces of selenium have been noticed by Kersten in an ore from Reinsberg near Freiberg; and that from Rammelsberg near Goslar must contain the same, it being one of the furnace products (Rg., Min. Ch., 120, 1860). Thallium is also present in some kinds, and more frequently present in this ore than in pyrite.

**Pyr., etc.**—In the closed tube decrepitates, and gives a sulphur sublimate, in the open tube sulphurous fumes. On charcoal fuses to a magnetic globule; with soda the roasted mineral gives a globule of copper containing iron. The roasted mineral reacts for copper and iron with the fluxes. Dissolves in nitric acid, excepting the sulphur, and forms a green solution; ammonia in excess changes the green color to a deep blue, and precipitates red ferric hydroxide.

**Obs.**—A widely disseminated mineral in metallic veins and nests in gneiss and crystalline schists, also in serpentine rocks; often intimately associated with pyrite, also with siderite, tetrahedrite, etc., sometimes with nickel and cobalt sulphides, pyrrhotite, etc. Observed coated with tetrahedrite crystals in parallel position, also as a coating over the latter.

Chalcopyrite is the principal ore of copper at the Cornwall mines; it is there associated with cassiterite, galena, bornite, chalcocite, tetrahedrite, sphalerite. The copper beds of Falun in Sweden are composed principally of this ore, which occurs in large masses surrounded by a coating of serpentine, and embedded in gneiss. At Rammelsberg, near Goslar in the Harz, it forms a bed in argillaceous schist, and is associated with pyrite, galena, sphalerite, and minute portions of silver and gold; associated with nickel and cobalt ores in the Kupferschiefer of Mansfeld. The Kurprinz mine at Freiberg affords well-defined crystals; also Horhausen, Dillenburg, Neudorf, Müsen; Schlackenwald in Bohemia. It occurs also in the Banat, Hungary, and Thuringia; in Scotland in Kirkcudbrightshire, Perthshire and elsewhere; at Mte. Catini in Tuscany: at New South Wales; in South Australia. Extensively worked in Namaqualand, S. Africa; in fine crystals at Cerro Blanco, near Copiapo, Chili, and elsewhere in large deposits.

In *Maine*, at the Lubec lead mines; at Dexter. In *N. Hamp.*, at Franconia, in gneiss; at Unity, on the estate of Jas. Neal; Warren, on Davis's farm; at Eaton, 2 m. N.E. of Atkins's tavern; Lyme, E. of E. Village; Haverhill, etc. In *Vermont*, at Stafford, Corinth, Waterbury. Shrewsbury. In *Mass.*, at the Southampton lead mines; at Turner's falls on the Connecticut, near Deerfield, and at Hatfield and Sterling. In *Connecticut*, at Bristol and Middletown, sometimes in crystals. In *New York*, at the Ancram lead mine; five miles from Rossie, beyond De Long's mills at the Rossie lead mines, in crystals; in crystals and massive near Wurtzboro', Sullivan Co.; very large crystals (f. 4) and massive at Ellenville, Ulster Co. In *Pennsylvania*, at Phenixville; at the French Creek mines, Chester Co., with pyrite, magnetite, byssolite, calcite, etc., sometimes in large skeleton sphenoidal crystals formed by parallel grouping; also in small isolated crystals embedded in chlorite (figs. 8–15). In *Maryland*, in the Catoctin Mts.; between Newmarket and Taneytown; near Finksbury, Carroll Co., abundant (Patapsco and other mines), with bornite, carrollite, and malachite. In *Virginia*, at the Phenix copper mines, Fauquier Co., and the Walton gold mine, Louisa Co. In *N. Carolina*, near Greensboro', abundant massive (Fenress or North Carolina, and Macculloch mines), along with siderite in a quartz gangue. In *Tennessee*, 30 miles from Cleveland, in Polk Co. (Hiwassee mines). In *Missouri*, with sphalerite at Joplin, Jasper Co.

In *Cal.*, in different mines along a belt between Mariposa Co. and Del Norte Co., on west side of, and parallel to, the chief gold belt; occurring massive in Calaveras Co., at Union, Keystone, Empire, Napoleon, Campo Seco, and Lancha Plana mines, and in crystals on Domingo Creek; in Mariposa Co., at the La Victoire and Haskell claims, and on the Chowchillas river; in Amador Co., at the Newton mine; in El Dorado Co., at the Cosumnes, Hope Valley, Bunker Hill, El Dorado, Excelsior mines; in Plumas Co., at the Genesee and Cosmopolitan mines. Abundant in *Montana*, near Butte, with bornite, pyrite, etc., also at other points, and often argentiferous and auriferous. In *Colorado* abundant in Gilpin, Boulder, Chaffee, Gunnison Counties, etc.; commonly associated with pyrite, tetrahedrite, sphalerite, and often highly argentiferous; well crystallized and sometimes coated with tetrahedrite in the mines near Central City. Also mined in Arizona, Utah, but in most cases chiefly for silver and gold. Grant Co., New Mexico.

In *Canada*, in Perth and near Sherbrooke and at many points in the eastern part of the province of Quebec; in the Nipissing distr., Ontario, at various points; extensively mined at Sudbury; at the Bruce mines, on Lake Huron; at Point-au-Mines and elsewhere on Lake Superior.

**Alt.**—Changes on exposure with moisture, especially if heated, to a sulphate. Malachite, covellite, chrysocolla, melaconite, chalcocite, and iron oxide are other forms into which it is sometimes altered; also to tetrahedrite.

Named from *χαλκός*, *brass*, and *pyrites*, by Henckel, who observes in his Pyritology (1725) that chalcopyrite is a good distinctive name for the ore. Aristotle calls the copper ore of Cyprus *chalcitis;* and Dioscorides uses the same word; but what ore was intended is doubtful. There is no question that copper-pyrites was included by Greek and Latin authors under the name *pyrites* (q.v., p. 86).

**Artif.**—Obtained in crystals by the action of $H_2S$ upon a mixture of $2CuO,Fe_2O_3$ slightly heated in a glass tube, Doelter, Zs. Kr., **13**, 35, 1885. Has been observed as a furnace-product. Occurs as a recent formation at Bourbonne-les-Bains (Daubrée).

**Ref.**—[1] Mem. Wern. Soc., **4**, 1, 1822, also Ed. J. Sc., **3**, 66, 1825. Haidinger first correctly determined the system to which the crystals belong, gave accurate measurements (confirmed by Sbk., and Kk., Min. Russl., **6**, 277), and described the three twinning laws.

[2] Mlr. Min., p. 182, 1852; Sbk., monograph, Zs. G. Ges., **20**, 595, 1868. [3] Sbk., l. c. [4] Schimper, Min.-Samml. Strassburg, 53, 1878. [5] Rath, Anxbach, Ber. nied. Ges., Jan. 9, 1882. [6] Mayer, Holzheim, Zs Kr., **13**, 47, 1887. [7] Pfd., Am. J. Sc., **40**, 207, 1890. [8] Cf. Fletcher, Phil. Mag., **14**, 276, 1882; Zs. Kr., **7**, 321, 1882.

**BARNHARDTITE** *Genth*, Am. J. Sc., **19**, 17, 1855; **28**, 247, 1859. Compact massive. Fracture conchoidal, uneven. Brittle. H. = 3·5. G. = 4·521. Luster metallic. Color bronze-yellow. Streak grayish black, slightly shining. Tarnishes easily, giving pavonine tints, or becoming pinchbeck-brown.

**Anal.**—1, W. J. Taylor, Am. J. Sc., **19**, 18, 1855. 2, F. A. Genth, ibid. 3, P. Keyser, ibid. 4, Higgins, ibid., **45**, 319, 1868.

| | S | Fe | Cu | |
|---|---|---|---|---|
| 1. Barnhardt's Land | 29·40 | 22·23 | 47·61 | Ag *tr.* = 99·24 |
| 2. Pioneer Mills | 29·76 | 22·41 | 46·69 | = 98·86 |
| 3. " " | 30·50 | 21·08 | 48·40 | = 99·98 |
| 4. Bill Williams' Fork | 28·96 | 20·44 | 50·41 | = 99·81 |

Occurs in N. Carolina with other copper ores, on Dan Barnhardt's land, Pioneer Mills, Phenix mine, and Vanderburg mine, in Cabarrus Co.; also near Charlotte, Mecklenburg Co.;

at Bill Williams' Fork, in California, with chalcopyrite, etc. It may be a chalcopyrite, partly altered to chalcocite, as would be inferred from Genth's later observations.

HOMICHLIN *Breithaupt*, B. H. Ztg., **17**, 385, 424, 1858; **18**, 65, 321, 1859. Closely related to the preceding, and may be chalcopyrite partly altered to bornite. Occurs in tetragonal octahedral crystals, but mostly massive; H. = 4–5; G. = 4·472–4·480; color more bronze-like than in chalcopyrite; streak black. Analysis by Richter, ibid., **18**, 321:

S 30·21 Fe 25·81 Cu 43·76 = 99·78

Occurs with malachite and other copper ores at Plauen in Voigtland; also said to occur, by Breithaupt, in Bavaria, Hesse and Nassau, Silesia, the Harz, at Rheinbreitbach on the Rhine, in Algeria, in Chili at Remolinos and Tocopilla, and in Japan.

DUCKTOWNITE *Shepard*. A blackish copper ore from Ducktown, Tenn. G. J. Brush has shown that it is not homogeneous, and only a mixture, grains of pyrite being visible through the mass, and also a softer gray mineral, which is probably chalcocite. See Rep. on Mt. Pisgah Copper Mine, N. Haven, 1859, and Am. J. Sc., **28**, 129, 1859.

**84. STANNITE.** Geschwefeltes Zinn (fr. Cornwall) *Klapr.*, Schriften Nat. Fr. Berlin, **7**, 169, 1787, Beitr., **2**, 257, 1797, **5**, 228, 1810. Zinnkies *Wern.*, Bergm. J., 1789. 385, 397. Tin Pyrites *Kirw.*, **2**, 300, 1796. Bell Metal Ore. Etain sulfuré *Fr.* Stannine *Beud.*, Tr., **2**, 416, 1832.

Massive, granular, and disseminated[1].

Cleavage: cubic, indistinct. Fracture uneven. Brittle. H. = 4. G. = 4·3–4·522; 4·506, Zinnwald, Rg. Luster metallic. Streak blackish. Color steel-gray to iron-black, the former when pure; sometimes a bluish tarnish; often yellowish from the presence of chalcopyrite. Opaque.

**Comp.**—A sulphide of tin, copper, iron and sometimes zinc, perhaps $Cu_2S.FeS.SnS_2$ = Sulphur 29·9, tin 27·5, copper 29·5, iron 13·1 = 100.

**Pyr., etc.**—In the closed tube decrepitates, and gives a faint sublimate; in the open tube sulphurous fumes. B.B. on charcoal fuses to a globule, which in O.F. gives off sulphur, and coats the coal with tin dioxide; the roasted mineral treated with borax gives reactions for iron and copper.

Decomposed by nitric acid, affording a blue solution, with separation of sulphur and tin dioxide.

**Obs.**—Formerly found at Wheal Rock, Cornwall, and at Carn Brea, where it constituted a considerable vein, and was accompanied by pyrite, sphalerite, and other minerals; more recently in considerable quantity in granite at St. Michael's Mount; also at Stenna Gwynn, St. Stevens, and at Wheal Primrose, Wheal Scorrier, and occasionally at Botallack mine, St. Just; also at the Cronebane mine, Co. Wicklow, in Ireland; Zinnwald, in the Erzgebirge, with sphalerite and galena. It frequently has the appearance of bronze or bell metal, and hence the name *bell-metal ore*.

**Ref.**—[1] Usually accepted as tetrahedral upon the authority of Breithaupt; this, however, is stated by Weisbach (priv. contrib.) to be a mistake, the observations having been made upon a specimen of tetrahedrite from South America, not upon stannite.

Twins: tw. ax *a*, usually penetration-twins (f. 11) with parallel axes; rarely contact-twins. Cube and the pyritohedron *e* (210) most common forms, the faces of both often striated in one direction ‖ edge *a*/*e*, the striation due to oscillatory combination of these forms and tending to produce rounded faces (f. 5); pyritohedral faces also striated ⊥ to this edge; octahedron also common. Crystals sometimes acicular by elongation in direction of a cubic axis; also abnormally developed with tetragonal or orthorhombic symmetry (f. 7, 8).[14] Also frequently massive, fine granular; sometimes subfibrous radiated; reniform, globular, stalactitic.

Cleavage: *a*, *o* indistinct. Fracture conchoidal to uneven. Brittle. H. = 6–6·5.

G. = 4·95–5·10; 4·967 Traversella, 5·027 Elba, Rg. Luster metallic, splendent to glistening. Color a pale brass-yellow, nearly uniform. Streak greenish black or brownish black. Opaque. Shows both + and − varieties thermo-electrically[15]. Paramagnetic.

**Comp., Var.**—Iron disulphide, $FeS_2$ = Sulphur 53·4, iron 46·6 = 100.

Nickel, cobalt, and thallium, and also copper in very small quantities, sometimes replace part of the iron, or else occur as mixtures. Gold is sometimes present, distributed invisibly through it, auriferous pyrite being an important source of gold. Thallium occurs in traces in much pyrite, showing its presence often in the chimneys of furnaces where pyrite, or ores containing it, are roasted. A variety from near Ribadeo in Galicia, from which tin and zinc were obtained, has been called *ballesterosite*, after Lopez Ballesteros, Schulz and Paillette, Bull. G. Fr. **7**, 16, 1849. Pyrite sometimes contains traces of selenium.

Arsenic is rarely present, a variety in octahedral crystals from French Creek, Penn., gave Hamburger (cf. Genth, Am. J. Sc., **40**, 114, 1890):

S 54·08 As 0·20 Fe 44·24 Co 1·75 Ni 0·18 Cu 0·05 = 100·50

For analyses of pyrite, see Mène, C. R., **64**, 867, 1867, also Girard and Morin, Ann. Ch. Phys., **7**, 229, 1876.

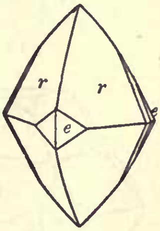
8.



Figs. 1–6, Simple forms. 7, 8, French Creek, Pfd.[14]

**Pyr., etc.**—In the closed tube a sublimate of sulphur and a magnetic residue. B.B. on charcoal gives off sulphur, burning with a blue flame, leaving a residue which reacts like pyrrhotite. Insoluble in hydrochloric, but decomposed by nitric acid.

**Obs.**—Pyrite occurs abundantly in rocks of all ages, from the oldest crystalline to the most recent alluvial deposits. It usually occurs in small cubes, pyritohedrons, or in more highly modified forms; also in irregular spheroidal nodules and in veins, in clay slate, argillaceous sandstones, the coal formation, etc.

Crystals have been observed associated in parallel position with those of marcasite, also with arsenopyrite.

Cubes of gigantic dimensions have been found in some of the Cornish mines; pyritohedrons and other forms in great variety occur with hematite on the island of Elba, sometimes five to six inches in diameter; also with magnetite at Traversella in Piedmont, and at Brosso in fine crystals. Other localities for crystals are Müsen near Siegen; Freiberg, Saxony; Schneeberg; Waldenstein in Carinthia; Příbram, Bohemia; Schemnitz, Hungary; large octahedral crystals are found at Persberg in Sweden. Magnificent crystals come from Peru. Alston-Moor, Derbyshire, Falun and Långban in Sweden, Kongsberg in Norway, are well-known localities The clay at Vlotho near Minden, Westphalia, and the chalk at Lewes in Surrey, have afforded some remarkable compound crystals. It has also been met with in the Vesuvian lavas.

In *Maine*, at Corinna, Peru, Waterville, and Farmington, in crystals; at Bingham (sawmills), Brooksville, and Jewell's Id., massive. In *N. Hampshire*, at Unity, massive. In *Mass.*, at Heath, in cryst.; at Rowe, Hawley and Hubbardston, massive. In *Vermont*, at Shoreham, in limestone, crystals abundant; Hartford, in cubes 2–4 in. In *Conn.*, at Lane's mine, Monroe, in octahedrons; Orange and Milford, in cubes in chlorite slate; Middletown lead mine, sometimes acicular; Roxbury, finely crystallized; at Stafford, in mica slate; massive at Colchester, Ashford, Tolland, Stafford, and Union. In *N. York*, at Rossie, fine crystals (dodecahedral, f. 14) occur at the lead mine in green shale; at Schoharie, a mile west of the court-house, in single and compound crystals, often highly polished and abundant; in interesting crystals at Johnsburgh and Chester, Warren Co.; in gneiss near Yonkers; in Orange Co., at Warwick and Deerpark; in Jefferson Co., in Champion and near Oxbow on the banks of Vrooman's lake, in modified octahedrons; massive in Franklin, Putnam, and Orange Cos., etc. In *Pennsylvania*, in crystals at Little Britain, Lancaster Co.; at Chester, Delaware Co.; in Carbon and York Cos.; at Knauertown, Chester Co.; at French Creek mines, octahedrons and other forms, sometimes tetragonal or orthorhombic in symmetry. In Cornwall, Lebanon Co., in lustrous cubo-octahedrons. with a steel tarnish; in *N. Car.*, near Greensboro', Guilford Co., in crystals. In *Colorado* in fine complex crystals in mines near Central City, Gilpin Co., and elsewhere. Auriferous pyrite is common at the mines of Colorado, and many of those of California, as well as in Virginia and the States south.

In *Canada*, 2 miles N. W. of Brockville, Ontario, a cobaltiferous var., in the Laurentian; on the river Assumption, seignory of Daillebout, and at Escott, a niccoliferous var., containing also some cobalt.

Large quantities of massive pyrite are mined at the Rio Tinto and other mines in Spain, also in Portugal. Among important deposits in the U. S. are those at Rowe, Mass.; Herman, St. Lawrence Co., and Ellenville, Ulster Co., N. Y.; Tolersville, Louisa Co., Va.; Dallas, Paulding Co., Ga.

), 13, Gilpin Co., Col , Ayres. 10, Elba. 11, Vlotho. Westphalia, Sbk. 12. Elba, Svr. 14, Rossie.

The name *pyrite* is derived from πῦρ, *fire*, and alludes to the sparks from friction. Pliny nentions several things as included under the name (36, 30): (1) a stone used for grindstones; (2) a kind which so readily fires punk or sulphur that he distinguishes it as *pyrites vivus*, and which may have been flint or a related variety of quartz, as has been supposed, but more probably was *emery*, since he describes it as the heaviest of all; (3) a kind resembling brass or copper; (4) a porous stone, perhaps a sandstone or buhrstone. The brassy kind was in all probability our pyrite. But with it were confounded copper pyrites (chalcopyrite), besides marcasite and pyrrhotite, although these three kinds of pyrites fail of the scintillations. In fact, Dioscorides calls pyrite an ore of copper, yet in the next sentence admits that some kinds contain no copper; and, moreover, he states that the mineral gives sparks. This confounding of iron and copper pyrites is apparent also in the descriptions of the vitriols (sulphates of iron and copper) by Pliny and other ancient writers, and equally so in the mineralogy of the world for more than fifteen centuries after Pliny, as is even now apparent in the principal languages of Europe; *Kupferwasser* (copper-water) of the Germans being the copperas of the English and couperose of the French. It is quite probable that *copperas* and *couperose* are in fact corruptions of the German word, instead of derivatives from *cuprosa* or *cuprirosa*, as usually stated, for the Latin *u* would not have become *ou* in French.

Under the name *marcasite* or *marchasite*, of Spanish or Arabic origin, the older mineralogists Henckel, Wallerius, Linnæus, etc., included distinctively crystallized pyrite, the cubic preëminently; the nodular and other varieties being called *pyrites*, and the less yellow or brownish and softer kinds, *wasserkies*, this last including our *marcasite* and *pyrrhotite*, and some *true pyrite*. Werner first made *pyrrhotite* a distinct species. The "marcasite" used for personal ornaments in the last century was pyrite.

**Alt.**—Pyrite readily changes to an iron sulphate by oxidation, some sulphur being set free. Also to limonite on its surface, and afterward throughout, by the action of a solution of bicarbonate of lime carrying off the sulphuric acid as change proceeds, and from limonite to red iron oxide. Green vitriol, limonite, göthite, hematite, quartz, graphite, ochreous clay, occur as pseudomorphs after pyrite. Cf. also marcasite on the relative stability of the two compounds.

**Artif.**—May be made by the slow reduction of ferric sulphate in presence of some carbonate. Also by heating together iron sesquioxide, sulphur, and sal ammoniac (Wöhler), the crystals obtained seemed to have a *tetrahedral* form; cf. Weinschenk, Zs. Kr., **17**, 487, 1890. See further Fouqué-Lévy, Synth. Min., 321, 1882, and Doelter, Zs. Kr., **11**, 30, 1885.

Pyrite has been observed as a recent formation at Bourbonne-les-Bains, Daubrée, C. R., **80**, 605, 1875.

**Ref.**—[1] See Strüver, Mem. Acc. Torino, **26**, 1869, and Att. Acc. Torino, **6**, 374, 1871, for list of planes with early authorities, and many new forms; also Helmhacker, Min. Mitth., 13, 1876. Koksharov adds (962) from A. Nordenskiöld, whose 3-$\frac{2}{3}$ is, however, an obvious misprint for 3-$\frac{3}{2}$.

On elasticity, Voigt, Nachr. Ges. Göttingen, 310, 1888. On etching experiments see Becke, Min. Mitth., **8**, 239, 1886, **9**, 2, 1887.

**86. HAUERITE.** Hauerit *Haid.*, Nat. Abh. Wien, **1**, 101, 107, 1846, or Pogg., **70**, 148, 1847.

Isometric; pyritohedral. Observed forms:

*a* (100, *i-i*) *d* (110, *i*) *o* (111, 1) *f* (310, *i*-3) *e* (210 *i*-2) *s* (321, 3-$\frac{3}{2}$)

Commonly in octahedrons; sometimes in globular clusters.

Cleavage: cubic, imperfect. Fracture uneven to subconchoidal. Brittle. H. = 4. G. = 3·463. Luster metallic-adamantine. Color reddish brown, brownish black. Streak brownish red.

**Comp.**—Manganese disulphide, $MnS_2$ = Sulphur 53·9, manganese 46·1 = 100.

**Anal.**—1, Patera, quoted by Haid. 2, E. Scacchi, Rend. Accad. Napoli, April 1890.

| | | S | Mn | Fe | |
|---|---|---|---|---|---|
| 1. Kalinka | | 53·64 | 42·97 | 1·30 | $SiO_2$ 1·20 = 99·11 |
| 2. Sicily | G. = 3·366–3·411 | 53·76 | 46·05 | — | = 99·81 |

**Pyr.**—In the closed tube a sublimate of sulphur; in the open tube sulphurous fumes, and becomes green. On charcoal sulphurous fumes; the roasted mineral reacts for manganese with the fluxes.

**Obs.**—From Kalinka, Hungary, in clay with gypsum, sulphur, and realgar in a region like a solfatara: trachytic, and other eruptive rocks decomposing and adding to the clay, and the sulphur given off at the same time making depositions of sulphur and sulphides. One crystal found measured 1¼ inches through. The hauerite crystals are sometimes coated with pyrite; an unknown flesh-red or greenish mineral also accompanies it. Also in the crystalline schists of the Wakalipu district, New Zealand (Cox, Trans. N. Z. Inst., **14**, 426, 1881). At Raddusa, Catania, Sicily, in octahedral crystals at a depth of 50 meters embedded in a clay carrying layers of sulphur, gypsum and calcite.

**Artif.**—Synthetic experiments partially successful, Doelter, Zs. Kr., **11**, 32, 1885.

**87, 88. SMALTITE-CHLOANTHITE.**

**Smaltite.** ?Cobaltum cineraceum *Agric.*, 459, 1529. Koboltmalm, Koboltglants, Minera Cobalti cinerea, Cobaltum arsenico mineralisatum, pt. (Cobaltite here included), *Wall.*, 231, 1747. ?Cobaltum Ferro et Arsenico mineralisatum, Glants-Cobalt (fr. Schneeberg), *Cronst.*, 212, 1758. Mine de Cobalt grise *De Lisle*, Crist., 333, 1772; Mine de Cobalt arsenicale *De Lisle*, **3**, 123, 1783. Weisser Speisskobold, Grauer Speisskobold, *Wern.* Gray Cobalt ore *Kirw.*, 1796. Tin-white cobalt. Speiskobalt *Hausm.*, Handb., 155, 1813. Smaltine *Beud.*, *Tr.*, **2**, 584, 1852.

**Chloanthite** *Breith.*, Pogg., **64**, 184, 1845. Weissnickelkies, Weissnickelerz pt. Weisser Kupfernickel, Arsenikuickel, *Rg.* Rammelsbergit *Haid.*, Handb., 560, 1845. Chathamite *Shepard*, Min., 158, 1844; Am. J. Sc., **47**, 351, 1844.

Isometric; pyritohedral, Groth[1]. Observed forms[1]:

*a* (100, *i-i*); *d* (110, *i*); *o* (111, 1); *n* (211, 2-2); ϵ (10·1·0, *i*-10), δ (510, *i*-5), *f* (310, *i*-3); *x* (831, 8-$\frac{8}{3}$)?

Penetration-twins[2]: tw. pl. *o*, comp.-face 211, normal to *o*; often in complex and distorted forms. Also massive, and in reticulated and other imitative shapes.

Cleavage: *o* distinct; *a* in traces. Fracture granular and uneven. Brittle. H. = 5·5–6. G. = 6·4 to 6·6. Luster metallic. Color tin-white, inclining, when massive, to steel-gray, sometimes iridescent, or grayish from tarnish. Streak grayish black. Opaque. Shows both + and − varieties thermo-electrically.

**Comp.**—SMALTITE is essentially cobalt diarsenide, $CoAs_2$ = Arsenic 71·8, cobalt 28·2 = 100. CHLOANTHITE is nickel diarsenide, $NiAs_2$ = Arsenic 71·9, nickel 28·1 = 100.

Cobalt and nickel are usually both present, and thus these two species graduate into each other, and no sharp line can be drawn between them. Iron is also present in varying amount; the variety of chloanthite containing much iron has been called *chathamite*, a name given by Shepard to the mineral from Chatham, Conn. Further sulphur is usually present, but only in small quantities. Sometimes argentiferous, anal. 20.

Many analyses do not conform even approximately to the formula $RAs_2$, the ratio rising from less than 1 : 2 to 1 : 2·5 and nearly 1 : 3, thus showing a tendency toward skutterudite ($RAs_3$), perhaps due to either molecular or mechanical mixture. Part of the variation is due to want of homogeneity in the substances analyzed. Baumhauer has shown that even the crystals often have a zonal structure, Zs. Kr., **12**, 18, 1886. Moreover, Volkhardt has analyzed such crystals, and shown that, after being acted upon by hydrochloric acid and potassium chlorate, a part containing less arsenic went into solution, and the residue was richer in arsenic than the original (76·19 p. c. and 73·46 in one case). Similarly the same author found skutterudite ($RAs_3$) to be more difficultly soluble than smaltite and chloanthite. Zs. Kr., **14**, 407, 1888.

Much that has been called smaltite (speiskobalt) is shown by the high specific gravity to belong to the species safflorite, p. 100. Without the determination of either the form or specific gravity the classification is uncertain.

[a] Ni : Co = 3 : 1 approx.

Analysis 2 by McCay is of the Schneeberg ore called *Wismuthkobalterz* by Kersten (Schw. J., **47**, 265, 1826), and from which he obtained: ($\frac{4}{4}$) As 77·96, S 1·02, Co 9·89, Ni 1·11, Fe 4·77, Cu 1·30, Bi 3·89 = 99·94. Breithaupt called it cheleutite (cf. McCay, p. 25). It is isometric, with cubic habit and cleavage; H. = 5; color slate-gray. McCay shows that the bismuth, of which he obtained 0·78 p. c., is an impurity; the ratio of R : As = 1 : 2·80, which with the cubic cleavage shows it to be closely allied to skutterudite.

**Pyr., etc.**—In the closed tube gives a sublimate of metallic arsenic; in the open tube a white sublimate of arsenic trioxide, and sometimes traces of sulphur dioxide. B.B. on charcoal gives an arsenical odor, and fuses to a globule, which, treated with successive portions of borax-glass, affords reactions for iron, cobalt, and nickel.

**Obs.**—Usually occurs in veins, accompanying ores of cobalt or nickel, and ores of silver and copper; also, in some instances, with niccolite and arsenopyrite; often having a coating of annabergite.

Occurs with silver and copper at Freiberg, Annaberg, and particularly Schneeberg in Saxony; at Joachimsthal in Bohemia, the reticulated varieties frequently found embedded in calcite; also at Wheal Sparnon in Cornwall; at Riechelsdorf in Hesse, in veins in the copper schist; at Tunaberg in Sweden; Allemont in Dauphiné; at the silver mines of Tres Puntas and others in Chili, but only in small quantities.

At Chatham, Conn., the chloanthite (*chathamite*) occurs in mica slate, associated generally with arsenopyrite and sometimes with niccolite. At Franklin Furnace, N. J., at the Trotter zinc mine in octahedral crystals (anal. 17) with traces of a pyritohedron (20·1·0)?.

**Alt.**—Occurs altered to erythrite (arsenate of cobalt), a change due to the oxidation of the arsenic and cobalt on exposure to moisture.

**Ref.**—[1] Groth, Pogg., **152**, 249, 1874; Min.-Samml. Strassburg, p. 43, 1878; Naumann, Pogg., **7**, 337, 1826, **31**, 537, 1834. [2] Rath, Zs. Kr., **1**, 8, 1877; cf. Groth, Min.-Samml., p. 44.

**89. COBALTITE.** Cobaltum cum ferro sulfurato et arsenicato mineralisatum, Glants-Kobolt pt. (fr. Tunaberg), *Cronst.*, 213, 1758. Mine de Cobalt blanche *de Lisle*, Crist, 334, 1772. Glanzkobaltkies *Glock.*, Grundr., 1831. Cobaltine *Beud.*, Tr. **2**, 450, 1832. Koboltglans *Swed.* Sehta *Indian jewelers.*

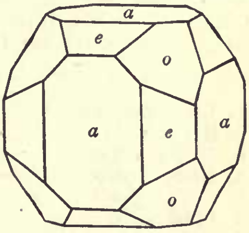
Isometric; pyritohedral. Observed forms[1]:

*a* (100, *i-i*) *o* (111, 1) *e* (210, *i*-2) *ω* (522, $\frac{5}{2}$-$\frac{5}{2}$) *s* (321, 3-$\frac{3}{2}$)
*d* (110, *i*) *h* (410, *i*-4) *p* (221, 2) *χ* (433, $\frac{4}{3}$-$\frac{4}{3}$) *y* (432, 2-$\frac{4}{3}$)

Commonly in cubes, *a*, or pyritohedrons, *e*, or combinations of these, with faces striated as in pyrite (cf. f. 1–5, p. 85); also with *o*. Also lamellar, granular massive to compact.

Cleavage: cubic, rather perfect. Fracture uneven. Brittle. H. = 5·5. G. = 6–6·3. Luster metallic. Color silver-white, inclined to red; also steel-gray, with a violet tinge, or grayish black when containing much iron. Streak grayish black. Shows both + and – varieties thermo-electrically.[2]

**Comp.**—Sulph-arsenide of cobalt, CoAsS or $CoS_2.CoAs_2$ = Sulphur 19·3, arsenic 45·2, cobalt 35·5 = 100.



India, Mallet.

Iron is present, and in the variety *ferrocobaltite* in large amount; this is the so-called *Stahlkobalt*, Rg. 4th Suppl., 116, 5th, 148, 1853; ferrocobaltine, Dana Min., 58, 1854.

The mineral analyzed by McCay had H. = 5, and gave in the closed tube a distinct sublimate of arsenic sulphide and metallic arsenic, like arsenopyrite.

**Pyr., etc.**—Unaltered in the closed tube. In the open tube gives sulphurous fumes, and a crystalline sublimate of arsenic trioxide. B.B. on charcoal gives off sulphur and arsenic, and fuses to a magnetic globule; with borax a cobalt-blue color. Soluble in warm nitric acid, with the separation of sulphur.

**Obs.**—Occurs at Tunaberg, Riddarhyttan, and Hakansbö, in Sweden, in large, splendent, well-defined crystals; at the Ko and Bjelke mines of Nordmark; also at Skutterud in Norway. Other localities are at Querbach in Silesia; Schladming, Styria; Siegen in Westphalia (from the Hamberg mine the *ferrocobaltite*); Botallack mine, near St. Just, in Cornwall; Khetri mines, Rajputana, India, called *sehta* by the Indian jewelers, who use it for giving a blue color to gold ornaments, cf. p. 71.

**Ref.**—[1] See Phillips, Min. 278, 1823, also Naumann, Pogg., **16**, 486, 1829, Groth, Min.-Samml., 41. 1878; Zs. G. Ges., **23**, 661, 1871. [2] Cf. references under pyrite, p. 87.

**90. GERSDORFFITE.** Niccolum Ferro et Cobalto Arsenicatis et Sulphuratis mineralisatum, Kupfernickel, pt. (*white*, var. fr. Loos), *Cronst.*, 218, 1758, Ak. H. Stockh., 1751, 1754. Isometric; pyritohedral. Observed forms:

*a* (100, *i-i*) *o* (111, 1) *e* (210, *i*-2)

Also lamellar and granular massive.

Cleavage: cubic, rather perfect. Fracture uneven. Brittle. H. = 5·5. G. = 5·6–6·2. Luster metallic. Color silver-white to steel-gray, often tarnished gray or grayish black. Streak grayish black. Opaque.

**Comp.**—Essentially a sulph-arsenide of nickel, NiAsS or $NiS_2.NiAs_2$ = Sulphur 19·3, arsenic 45·3, nickel 35·4 = 100. Iron replaces the nickel, often to considerable amount; also sometimes cobalt.

With normal gersdorffite are classed a number of minerals, in part doubtless mixtures, which have yielded different results, many of them approximating toward chloanthite. The analyses below include some of these; see further 5th Ed., p. 73. Anal. 9 corresponds to $NiS_2.2NiAs_2$, the mineral had cubic cleavage.

**Pyr., etc.**—In the closed tube decrepitates, and gives a yellowish brown sublimate of arsenic trisulphide. In the open tube yields sulphurous fumes, and a white sublimate of arsenic trioxide. B.B. on charcoal gives sulphurous and garlic fumes and fuses to a globule, which, with borax-glass gives at first an iron reaction, and, by treatment with fresh portions of the flux, cobalt and nickel are successively oxidized.

Decomposed by warm nitric acid, forming a green solution, with the separation of sulphur.

**Obs.**—Occurs at Loos in Helsingland, Sweden; Lempälä, Finland; in the Albertine mine, near Harzgerode in the Harz, with chalcopyrite, galena, calcite, fluorite, and quartz; at

Schladming in Styria; Kamsdorf in Lower Thuringia; Haueisen, near Lobenstein, Voigtland; at the quicksilver mine and at Pfingstwiese, near Ems. At the Craigmuir mine, Loch Fyne, Scotland. Also found as an incrustation of cubes, on decomposed galena and sphalerite, at Phenixville, Pa.

Sommarugaite is stated to be an auriferous gersdorffite from Rezbanya, Hungary. Bull. Soc. Min., **1**, 143, 1878.

Tombazite, according to Zerrenner, is pyrite, from Lobenstein.

**91. CORYNITE.** Korynit *v. Zepharovich,* Ber. Ak. Wien, **51** (1), 117, 1865. Arsenantimonnickelglanz pt. *Germ.*

Isometric. In octahedrons, with convex faces. Also in globular groups.

Fracture uneven. H. = 4·5–5. G. = 5·994; 5·95–6·029 Zeph. Luster metallic. Color silver-white, inclined to steel-gray on fresh fracture. Streak black. Opaque.

**Comp.**—Essentially a sulph-arsenide of nickel like gersdorffite, but with antimony replacing part of the arsenic, and thus connecting it with the arsenical varieties of ullmannite; formula $Ni(As,Sb)S$.

**Anal.**—Payer, l. c.:

| | As | Sb | S | Ni | Fe |
|---|---|---|---|---|---|
| G. = 5·994 | 37·83 | 13·45 | 17·19 | 28·86 | 1·98 = 99·31 |

**Pyr., etc.**—In the open tube affords sulphurous fumes and a crystalline white sublimate of arsenic trioxide. In the closed tube also finally a narrow yellowish-red and a broader yellow zone. B.B. on charcoal fuses easily at surface, yielding sulphurous and arsenical fumes. With borax-glass reactions for iron, cobalt, and finally nickel, with an arsenical odor.

**Obs.**—From Olsa, in Carinthia, with bournonite; crystals about 2½ mm. through.

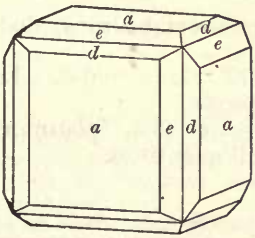
Named from *κορύνη, a club.*

**92. ULLMANNITE.** Nickelspiesglaserz (fr. Siegen) *Ullmann* (his discov. in 1803), Syst.-Tab., 166, 379, 1814. Nickelspiessglanzerz *Hausm.*, Handb., 192, 1813. Antimonnickelglanz, Nickelantimonglanz, Antimon-Arseniknickelglanz, Arsenantimonnickelglanz pt. *Germ.* Nickel Stibine; Nickeliferous Gray Antimony. Antimoine sulfuré nickelifère *H.*, 1822. Ullmannit *Fröbel*, 1843.

Isometric: pyritohedral,[1] Klein; tetrahedral, Zeph.[2] Observed forms:

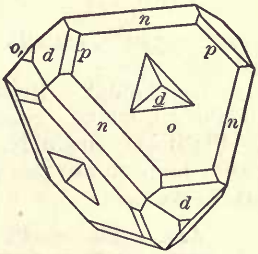
*a* (100, *i-i*), *d* (110, *i*), *o* (111, 1), *e* (210, *i*-2), *p* (221, 2), *q* (331, 3), *ξ* (881, 8), *n* (211, 2-2).

1.



Sarrabus, Klein

2.



Lölling. Zeph.

In crystals from Sarrabus[1] with *a, d, e* and rarely *q* with pyritohedral striations on *a* (f. 1). Also from the Lölling[2] in tetrahedral crystals with *d, o, o,, n, n,, p, ξ*; also in tetrahedrite-like twins with parallel axes (f. 2). These two varieties have the same composition (anal. 4, 5) and their relation is somewhat uncertain, cf. Klein[3]. It may be noted that artificial crystals of pyrite, of apparent tetrahedral form, have been described.

Also massive, structure granular.

Cleavage: cubic, perfect. Fracture uneven. Brittle. H. = 5–5·5. G. = 6·2–6·7. Luster metallic. Color steel-gray inclining to silver-white. Streak grayish black.

**Comp.**—Sulph-antimonide of nickel, $NiSbS$ or $NiS_2.NiSb_2$ = Sulphur 15·2, antimony 57·0, nickel 27·8 = 100. Arsenic is usually present in small amount.

**Anal.**—1, H. Rose, Pogg., **15**, 588, 1829. 2, Rg., Pogg., **64**, 189, 1845. 3, Lill, Vh. G. Reichs., 131, 1871. 4, 5, Jannasch, Jb. Min., **2**, 169, 1887; also earlier, ibid., **1**, 186, 1883. 6, Gintl, Ber. Ak. Wien, **60** (1), 812, 1869. 7, Behrendt, Rg., Min. Ch., 41, 1875. 8, Ullik Ber. Ak. Wien, **61** (1), 17, 1870; also other analyses on less pure material.

| | | Sb | As | S | Ni | |
|---|---|---|---|---|---|---|
| 1. Siegen | | 55·76 | — | 15·98 | 27·36 | = 99·10 |
| 2. Harzgerode | G. = 6·506 | 50·84 | 2·65 | 17·38 | 29·43 | Fe 1·83 = 102·13 |

| 6. " " | G. = 6·74 | 52·56 | 3·23 | 15·73 | 28·48 | = 100 |
| 7. Nassau | | 50·56 | 5·08 | 16·00 | 26·05 | Co 1·06, Fe 0·43, Cu 0·40 = 99·58 |
| 8. Waldenstein | G. = 6·53–6·56 | 56·01 | — | 14·81 | 28·85 | Pb 0·61 = 100·28 |

An alteration-product of the Waldenstein crystals gave Ullik (l. c., p. 19). after deducting impurities. Sb 52·44, O 16·15, CaO 13·52, NiO 3·27, FeO 3·13, MgO 0·21, $H_2O$ 11·26 = 99·98. For this the formula $3CaO.2Sb_2O_5.6H_2O$ is calculated.

**Pyr., etc.**—In the closed tube gives a faint white sublimate. In the open tube sulphurous and antimonial fumes, the latter condensing on the walls of the tube as a white non-volatile sublimate. B.B. on charcoal fuses to a globule, boils, and emits antimonial vapors, which coat the coal white; treated with borax-glass, reacts like gersdorffite. Some varieties contain arsenic.

Decomposed by nitric acid, forming a green solution, with separation of sulphur and antimony trioxide.

**Obs.**—Occurs in the Duchy of Nassau, in the mines of Freusburg, with galena and chalcopyrite; in Siegen, Prussia; at Harzgerode and Lobenstein; also Lölling and Waldenstein in Carinthia; Montenarba, Sarrabus, Sardinia. Named after J. C. Ullmann (1771–1821).

**Ref.**—[1] Klein, Jb. Min., **1**, 180, 1883. [2] Zeph., Ber. Ak. Wien, **60** (1), 809, 1869. [3] Klein, Jb. Min., **2**, 169, 1887. See p. 1051. *Kallilite*, p. 1039, is NiBiS.

Rammelsberg calls an ore from Wolfsberg in the Harz *bournonit-nickelglanz.* It occurs in cubes; H. = 4·5. G. = 5·635–5·706. Analysis, Pogg., **77**, 254, 1849:

As 28·00 Sb 19·53 S 16·86 Ni 27·04 Co 1·60 Pb 5·13 Cu 1·33 Fe 0·51 = 100

Heusler describes a massive light to dark steel-gray ore from Gosenbach near Siegen. Analysis gave: Sb 32·90, As 5·27, S 34·40, Ni 27·43, Pb,Zn *tr.* = 100.

This corresponds to $3\ NiS.\left.\begin{matrix}\frac{1}{5}\,As\\ \frac{4}{5}\,Sb\end{matrix}\right\}S_3$. Ber. nied. Ges., p. 67, 1887.

### 93. SPERRYLITE. *Horace L. Wells*, Am. J. Sc., **37**, 67, 1889; S. L. Penfield, ib., p. 71.

Isometric; pyritohedral. Observed forms:

*a* (100, *i-i*) *d* (110, *i*) *o* (111, 1) *e* (210, *i*-2)

In minute crystals, usually in cubes, or cubo-octahedrons; dodecahedral and pyritohedral faces rare.

Fracture conchoidal. Brittle. H. = 6–7. G. = 10·602. Luster metallic, brilliant. Color tin-white. Streak black. Opaque.

**Comp.**—Platinum arsenide, $PtAs_2$ = Arsenic 43·5, platinum 56·5 = 100. Antimony and rhodium are also present in small quantities.

**Anal.**—H. L. Wells:

| | As | Sb | Pt | Rh | Pd | Fe | |
|---|---|---|---|---|---|---|---|
| $\frac{2}{2}$ | 40·98 | 0·50 | 52·57 | 0·72 | *tr.* | 0·07 | $SnO_2$ 4·62 = 99·46 |

**Pyr.**—B.B. decrepitates slightly. In the closed tube remains unchanged at the fusing point of glass. In the open tube gives readily a sublimate of arsenic trioxide and does not fuse if slowly roasted, but if rapidly heated it melts very easily after losing a part of the arsenic. When dropped on a red-hot platinum foil, instantly melts, gives off white fumes of arsenic trioxide having little or no odor, and porous excrescences are formed on the platinum which do not differ in color from the untouched foil.

**Obs.**—Found at the gold quartz Vermillion mine, district of Algoma, 22 miles west of Sudbury, Ontario, Canada; occurs with pyrite, chalcopyrite, and cassiterite as a loose material occupying small pockets in the decomposed ore. Also probably present in small amount disseminated through a nickel-iron sulphide, cf. p. 66.

Named after F. L. Sperry of Sudbury, Ontario, who first called attention to the mineral.

**Artif.**—The artificial $PtAs_2$ has long been known.

**94. LAURITE.** *F. Wöhler* Nachr. Ges. Göttingen, 155, 1866; 327, 1869.

Isometric. Observed forms:

*a* (100, *i-i*) *o* (111, 1) *e* (210, *i*-2) *m* (311, 3-3) *n* (211, 2-2)? *s* (321, 3-$\frac{3}{2}$)?

Commonly in minute octahedrons; faces often rounded like the diamond; also in spherical forms and grains.

Cleavage: *o* distinct. Fracture subconchoidal. Very brittle. H. = 7·5. G. = 6·99. Luster metallic, bright. Color dark iron-black; powder dark gray.

**Comp.**—Sulphide of ruthenium and osmium, probably essentially $RuS_2$ (cf. below).

**Anal.**—Wöhler, l. c., on 0·3 gr.

S 31·79 Ru 65·18[a] Os [3·03] = 100

[a] Containing some osmium.

**Pyr., etc.**—Heated it decrepitates. B.B. infusible, giving first sulphurous and then osmic fumes. Not acted upon by aqua regia, nor by heating with potassium disulphate.

**Obs.**—From the platinum washings of Borneo. Found among fine-grained platinum which had been brought from Borneo. Also reported as occurring with the platinum of Oregon.

Named by Wöhler as a compliment to the wife of a personal friend.

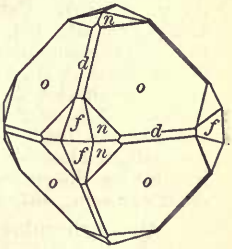
**Artif.**—St. Claire Deville and Debray have made artificially a ruthenium sulphide ($RuS_2$ = S 38·1, Ru 61·9 = 100) in isometric crystals, octahedrons, and cubes. Bull. Soc. Min., **2**, 185, 1879.

---

**95. SKUTTERUDITE.** Tesseral-Kies, Hartkobaltkies, *Breith.*, Pogg., **9**, 115, 1827. Arsenikkobaltkies *Scheerer*, Pogg., **42**, 553, 1837. Hartkobalterz, *Hausm.*, Handb., 69, 1847. Skutterudit *Haid.*, Handb., 560, 1845. Modumite *Nicol*, Min., 457, 1849.

Isometric; pyritohedral[3]. Observed forms[1]:

*a* (100, *i-i*), *d* (110, *i*), *o* (111, 1), *f* (130, − *i*-3)[2], *r* (332, $\frac{3}{2}$)[2], *n* (211, 2-2), *s* (321, 3-$\frac{3}{2}$)[3], *y* (643, 2-$\frac{3}{2}$)[2].



Skutterud, Fletcher.

Also massive granular.

Cleavage: *a* distinct; *d* in traces. Fracture uneven. Brittle. H. = 6. G. = 6·72–6·86. Luster bright metallic. Color between tin-white and pale lead-gray, sometimes iridescent. Shows both + and − varieties thermo-electrically[4].

**Comp.**—Cobalt arsenide, $CoAs_3$ = Arsenic 79·3, cobalt, 20·7 = 100.

**Anal.**—1, Scheerer, l. c. 2, 3, Wöhler, Pogg., **43**, 591, 1838.

| | | As | Co | Fe | |
|---|---|---|---|---|---|
| 1. | G. = 6·78 | 77·84 | 20·01 | 1·51 | S 0·69, Cu *tr.* = 100·05 |
| 2. *Cryst.* | | 79·2 | 18·5 | 1·3 | = 99·0 |
| 3. *Mass.* | | 79·0 | 19·5 | 1·4 | = 99·9 |

A "chloanthite" from Markirch in Alsace gave Vollkardt: As 77·94, Ni 12·01, Co 3·69, Fe 5·07; corresponding to $RAs_3$; it was in crystals (100, 111) with G. = 6·32. Other crystals are stated to have conformed to $RAs_2$. Zs. Kr., **14**, 408, 1888.

**Pyr.**—Reactions like those of smaltite, but gives a more copious sublimate of metallic arsenic in the closed tube.

**Obs.**—From Skutterud, near Modum, in Norway, in a hornblendic gangue in gneiss, with titanite and cobaltite, the crystals sometimes implanted on those of cobaltite.

**Ref.**—[1] Scheerer, l. c. [2] Rath, Pogg., **115**, 480, 1862. [3] Fletcher, Phil. Mag., **13**, 474, 1882, or Zs. Kr., **7**, 20, 1882; cf. also Rath, Zs. Kr., **14**, 257, 1888. [4] Schrauf and Dana, Ber. Ak Wien, **69** (1). 153, 1874.

A mineral from an unknown source in small crystals (not measured) in quartz has been analyzed by Ramsay (J. Ch. Soc., **29**, 153, 1876) and called a bismuth-skutterudite, but its homogeneity may well be questioned, the corrected results (after deducting $SiO,FeS_2$) are:

G. = 7·55 As 46·10 Bi 37·64 Co 10·18 Ni 5·66 Fe 0·55 = 100·13

## 2. Marcasite Group. $RS_2$, $RAs_2$, etc. Orthorhombic.

The species falling in this group are closely parallel to those of the Pyrite group, p. 84.

Twins: (1) tw. pl. *m* (f. 4), often repeated (f. 5), sometimes producing stellate fivelings (f. 3); also (2) tw. pl. *e*, less common (f. 6), the crystals crossing at angles of nearly 60°. Crystals commonly tabular ‖ *c*, also pyramidal; the brachydomes deeply striated ‖ edge *b/c*. In stalactites with radiating internal structure and exterior covered with projecting crystals. Also globular, reniform, and other imitative shapes.

Cleavage: *m* rather distinct; *l* in traces. Fracture uneven. Brittle. H. = 6–6·5. G. = 4·85–4·90. Luster metallic. Color pale bronze-yellow, deepening on exposure. Streak grayish or brownish black. Opaque.

**Comp.**—Iron disulphide, like pyrite, $FeS_2$ = Sulphur 53·4, iron 46·6 = 100.

**Var.**—The varieties that have been recognized depend mainly on state of crystallization. 1. *Radiated* (*Strahlkies*, Germ.): Radiated; also the simple crystals. 2. *Cockscomb P.* (*Kammkies*, Germ.): Aggregations of flattened twin crystals into crest-like forms. 3. *Spear P.* (*Speerkies*, Germ.): Twin crystals, with re-entering angles a little like the head of a spear in form 4. *Capillary* (*Haarkies*, Germ.): In capillary crystallizations.

5. *Hepatic P.* (*Leberkies*, Germ.) and *Pyrites fuscus* pt.: The massive of dull colors, being named from *ἧπαρ, liver;* but including, among the older mineralogists especially, brown specimens of any pyrite, altered more or less to limonite.

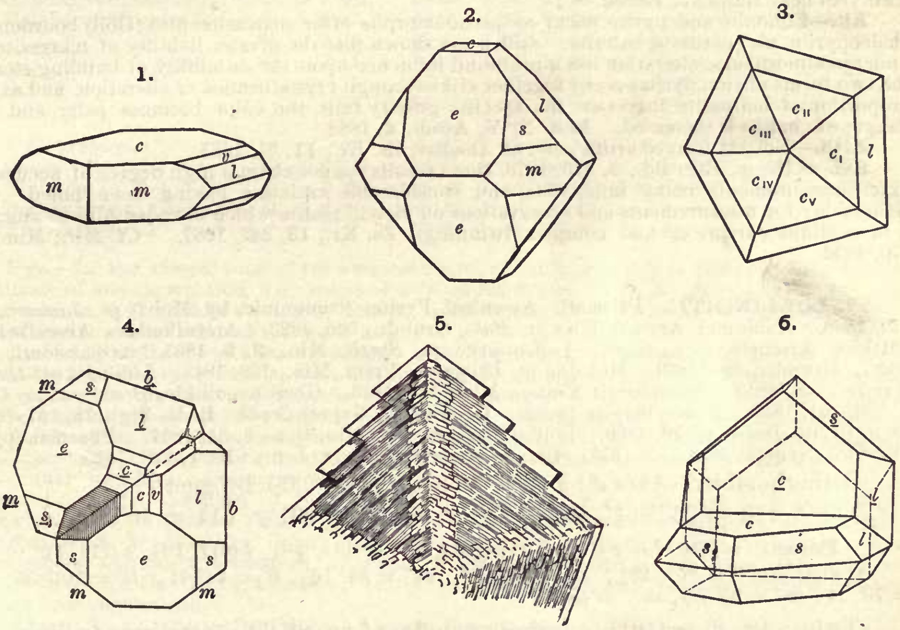
6. *Cellular P.* (*Zellkies*, Germ.): In cellular specimens, formed by the incrustation of the crystals of other minerals that have disappeared; partly pyrite.

7. *Arsenical:* Nearly white in color (in part *kyrosite* Breith., and *Weisskupfererz,* see below); contains a small amount of arsenic.

8. *Stalactitic:* In stalactites, sometimes with radiated structure, sometimes compact; the exterior distinct crystals, or rough; also in layers with galena or sphalerite, or both, resembling the "Schalenblende," and hence sometimes called "Schalenmarcasite."

**Pyr.,** etc.—Like pyrite; very liable to decomposition, more so than pyrite.

**Obs.**—The spear variety occurs abundantly in the plastic clay of the brown coal formation at Littmitz and Altsattell, near Carlsbad in Bohemia, and is extensively mined for its sulphur and the manufacture of ferrous sulphate. The radiated variety occurs at the same place; also at Joachimsthal, Bohemia, and in several parts of Saxony. The cockscomb variety occurs with galena and fluorite in Derbyshire; in chalk marl between Folkestone and Dover; Castleton in Derbyshire; near Alston Moor in Cumberland; near Tavistock in Devonshire; and radiated at East Wheal Rose and elsewhere in Cornwall. Schemnitz in Hungary, Andreasberg, Clausthal, etc., in the Harz are other localities.



1, Common Form. 2, Schemnitz, Sbk. 3, Freiberg, Id. 4, Galena, Ill. 5, Folkestone. 6, Freiberg, Sbk.

At Warwick, N. Y., it occurs in simple and compound crystals, in granite, with zircon. Hustis's farm, in Phillipstown, N. Y., affords small crystals, referred by Beck to this species, occurring in magnesian limestone. Massive fibrous varieties abound throughout the mica slate of New England, particularly at Cummington, Mass., where it is associated with cummingtonite and garnet. Occurs at Lane's mine, in Monroe, Conn., and in the topaz and fluorite vein in Trumbull; also in gneiss at East Haddam; at Haverhill, N. H., with common pyrite. Galena, Ill., in stalactites with concentric layers of sphalerite, galena, the exterior commonly marcasite in twin crystals pyramidal in aspect (f. 4). Mineral Point, Wis., in fine crystals; on sphalerite at Joplin, Mo. In Canada in Neebing, a few miles east of the Kamanistiquia R., north-west shore of L. Superior.

The word *marcasite,* of Arabic or Moorish origin (and variously used by old writers, for bismuth, antimony), was the name of common crystallized pyrite among miners and mineralogists in later centuries, until near the close of the last. It was first given to this species by Haidinger in 1845.

The species is probably recognized by Agricola under the name *wasserkies* and *lebererz,* and also under the same by Cronstedt; and it is *Wasserkies* of Hausmann in both editions of his great work. This name, wasserkies (pyrites aquosus, as Cronstedt translates it), is little applicable; yet may have arisen from the greater tendency of the mineral to become moist and alter to vitriol than pyrite—if it be not an early corruption, as Agricola seems to think (see above), of *Weisserkies* (white iron pyrites). It appears to have been used also for easily decomposable pyrite; and *pyrrhotite* was also included under its other name, *pyrites fuscus.* The rhombic crystallization is mentioned by de Lisle; but Haüy long afterward considered it only an irregularity of common iron pyrites. *Weisskupfererz* (also called *weisskupfer* and *weisserz*) occurs as the name of a species in all the mineralogical works of last century, from Henckel's Pyritology, in 1725, where it is called a whitish copper ore, and placed near tetrahedrite; and the light color, from Henckel down, is attributed to the presence of arsenic. It has finally been run out as mostly impure marcasite; and the domeykite and related species are now the only true white copper.

*Marcasite* is made by Breithaupt (J. pr. Ch., **4**, 257, 1835) a generic name for the various species of pyrites. He used the names *lonchidite* or *kausimkies* for varieties in which Plattner found 4·4 p. c. As; *kyrosite* or *weisskupfererz*, the latter an old term of varied signification; *hepatopyrite, leberkies* Werner; *hydropyrite* or weicheisenkies, wasserkies (see above). Cf. Frenzel, Min. Lex. Sachsen, pp. 197–201, 1874.

*Metalonchidite* of F. Sandberger (Oest. Jb. B. Hütt., **35**, 531, 1887) is a marcasite containing about half as much arsenic as Breithaupt's lonchidite. G. = 5·08. Analysis by F. Pecher gave: S 49·56, As 2·73, Fe 45·12, Ni 1·29, Cu 0·72, Pb 1·12, Ag 0·01 = 100·55. Locality, the St. Bernhard vein near Hausach, Baden.

**Alt.**—Limonite and pyrite occur as pseudomorphs after marcasite, also (Döll) bournonite, chalcopyrite, magnetite, sphalerite. Julien has shown that the greater liability of marcasite to undergo atmospheric alteration has a profound influence upon the durability of building-stones; the two forms of iron pyrites occur together either though crystallization or alteration, and as the proportion of marcasite increases, the specific gravity falls, the color becomes paler, and the danger of change is increased. Ann. N. Y. Acad., **4**, 1888.

**Artif.**—Not yet formed artificially, cf. Doelter, Zs. Kr., **11**, 31, 1885.

**Ref.**—[1] Pogg., Erg. Bd., 8, 625, 1878, these results cannot claim a high degree of accuracy, exact measurements being impossible and considerable variation having been noted. See Gehmacher for measurements and observations on vicinal planes which have led him to suggest a monoclinic parameter and complex twinning. Zs. Kr., **13**, 242, 1887. [2] Cf. Mlr., Min., p. 170, 1852.

**97. LÖLLINGITE.** Prismatic Arsenical Pyrites (communic. by Mohs) pt. *Jameson*, **3**, 272, 1820. Axotomer Arsenik-Kies pt. *Mohs*, Grundr., 525, 1823. Geyer) *Breith.*. B. H. Ztg., **25**, 167, 1866. Leucopyrite *Dana*, p. 76, 1868. Löllingite *Zeph.*, Vh. Min. Ges., **3**, 84, 1867. Pharmakopyrit *Weisbach*, Synops. Min., 57, 1875. Glaucopyrite *Sandberger*, J. pr. Ch., **1**, 230, 1870.

Orthorhombic. Axes $\breve{a} : \bar{b} : \dot{c} = 0·66888 : 1 : 1·2331$ Brögger[1].

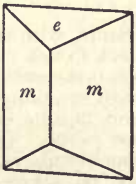
$100 \wedge 110 = 33^\circ\ 46\frac{2}{3}'$, $001 \wedge 101 = 61^\circ\ 31\frac{1}{3}'$, $001 \wedge 011 = 50^\circ\ 57\frac{1}{2}'$.

**Forms:** *m* (110, *I*) *e* (101, 1-ī) *u* (014, $\frac{1}{4}$-ĭ) *t* (013, $\frac{1}{3}$-ĭ) *l* (011, 1-ĭ) *o* (112, $\frac{1}{2}$).

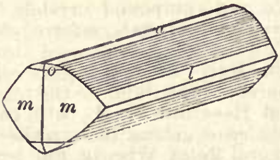
Angles: $mm''' = {}^*67^\circ\ 33\frac{1}{3}'$, $ee' = 123^\circ\ 3'$, $uu' = 34^\circ\ 16'$, $tt' = 44^\circ\ 41'$, $ll' = 101^\circ\ 55'$, $oo' = 76^\circ\ 14'$, $oo'' = 95^\circ\ 55'$, $oo''' = 48^\circ\ 46'$.

Twins: tw. pl. *e* (101), crossing at angles of nearly 60°, sometimes trillings.

1.



2.



Stokö, Brögger.

Cleavage: basal, sometimes distinct. Fracture uneven. Brittle. H. = 5–5·5. G. = 7·0–7·4 chiefly, also 6·8. Luster metallic. Color between silver-white and steel-gray Streak grayish black.

**Comp., Var.**—Essentially iron diarsenide, $FeAs_2$, but passing into $Fe_3As_4$; also tending toward arsenopyrite ($FeAsS$) and safflorite ($CoAs_2$). Bismuth and antimony are sometimes present.

**Var.**—1. *Löllingite*, $FeAs_2$ = Arsenic 72·8, iron 27·2 = 100. G. = 7·234 Hüttenberg, Zeph.
2. *Leucopyrite*, $Fe_3As_4$ = Arsenic 64·1, iron 35·9 = 100. G. = 7·0–7·2.
3. *Geyerite*, containing sulphur, anal., 17–20. G. = 6·25–6.8.
4. *Cobaltiferous*. Glaucopyrite belongs here, cf. anals. 6, 8, 9.

**Pyr.**—In the closed tube gives a sublimate of metallic arsenic; in the open tube a white sublimate of arsenic trioxide, with traces of sulphurous fumes. B.B. on charcoal gives the odor of arsenic; in O.F. a white coating of arsenic trioxide, and in R.F. a magnetic globule. With the fluxes the roasted mineral reacts for iron.

**Obs.**—Löllingite occurs with siderite, also bismuth and chloanthite, in the Lölling-Hüttenberg district in Carinthia; with niccolite at Schladming; at Ehrenfriedersdorf, in Saxony; Andreasberg in the Harz; at Sätersberg, near Fossum, in Norway; on Stokö and at other points in the augite-syenite of southern Norway, there associated with homilite and meliphanite.

The arsenical iron from Reichenstein, Silesia, is in part löllingite, but mostly leucopyrite; it often carries gold. *Geyerite* is from Geyer in Saxony, in crystals and massive with quartz; also from other localities. *Glaucopyrite* is from Guadalcanal, Andalusia, Spain. In the U. S., löllingite occurs at the head of Brush Creek, Gunnison Co., Colorado (anal. 6), it is often embedded in barite or siderite. Other localities for arsenical iron (not yet analyzed) are Edenville and Monroe, N. Y.; Roxbury, Conn.; Paris, Me. A crystal of arsenical iron, weighing two or three ounces, was found in Bedford Co., Penn., but it is not known under what circumstances; and in Randolph Co., N. C., a mass of nearly two pounds weight. The composition of these has not been determined.

Named by Chapman after Mohs. by whom the mineral was first described, and who mentions Lölling as the first locality at which it was found; but as *mohsite* was previously given to a variety of ilmenite. Haidinger's name was adopted in the 5th Ed., 1868, for the Reichenstein mineral, $Fe_3As_4$, and Shepard's name leucopyrite (from λευκος, *white*) given to the arsenical iron conforming to $FeAs_2$. A little earlier, however, the same names were used by Zepharovich, but reversed, löllingite for $FeAs_2$ and leucopyrite for $Fe_3As_4$; this arrangement was adopted in subsequent reprints of the 5th Ed. In view of the variation of composition of other minerals of this and of the corresponding isometric group (e.g., arsenopyrite, smaltite, etc.) it seems best to unite the varieties under the most generally accepted name.

**Ref.**—[1] Norway (anal. 4). Zs. Kr., **16**, 8, 1890. The measurements of Schrauf, Jb. Min., 677, 1875, were probably made on arsenopyrite from Mte. Challanches near Allemont, not löllingite as supposed, cf. Groth, Ber. Ak. München, 384, 1885.

PACITE *Breithaupt*, B. H. Ztg., **25**. 167, 1866. In form and color near arsenopyrite. G. = 6·3. An analysis by Winkler gave: As 64·84, S 7·01, Fe 24·35, Co 0·13, Cu 0·11, Bi 0·10, Au, Ag 0·006, gangue 2·88 = 99·426. From La Paz in Bolivia, in masses and thin plates in the gangue, with native gold and bismuth.

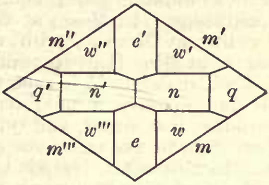
Twins: tw. pl. (1) *m*, as contact- or penetration-twins, sometimes repeated like marcasite (f. 5); (2) *e* in cruciform-twins (f. 6), also in trillings[5] sometimes star-shaped (f. 7) crossing at angles of 59° and 62°. Crystals prismatic *m*, or flattened vertically by the oscillatory combination of *n* (012). Brachydomes horizontally striated; also faces *m* often finely striated ‖ edges *m*/*e* or with *m*/*n*. Also columnar, straight, and divergent; granular, or compact.

Cleavage: *m* rather distinct; *c* in faint traces. Fracture uneven. Brittle. H. = 5·5–6. G. = 5·9–6·2; 6·269 Franconia, Kenng. Luster metallic. Color silver-white, inclining to steel-gray. Streak dark grayish black. Opaque. Thermo-electrically[7] both positive and negative.

**Comp., Var.**—Sulph-arsenide of iron, FeAsS or $FeS_2.FeAs_2$ = Arsenic 46·0, sulphur 19·7, iron 34·3 = 100. Part of the iron is sometimes replaced by cobalt.

8.



Schladming, after Rumpf.

**Var.**—1. *Ordinary.* Containing little or no cobalt. The analyses show considerable variation, and it has been proved that this is accompanied by a change in the angles, as exhibited below. Antimony is present in small amount (to 0·28 p. c.) Loczka. l. c.; also bismuth, Carnot, l. c. *Plinian* of Breithaupt, supposed to be monoclinic, belongs here, anal. 12; G. = 6·3.

2. *Cobaltiferous: Danaite.* Containing from 4 to 10 p. c. of cobalt replacing the iron, and thus graduating toward glaucodot.

3. *Niccoliferous.* Anal. 23.

**Pyr., etc.**—In the closed tube at first gives a red sublimate of arsenic trisulphide, then a black lustrous sublimate of metallic arsenic. In the open tube gives sulphurous fumes and a white sublimate of arsenic trioxide. B.B. on charcoal reacts like löllingite. The varieties containing cobalt give, after the arsenic has been roasted off, a blue color with borax-glass when fused in O.F. with successive portions of flux until all the iron is oxidized. Gives fire with steel, emitting an alliaceous odor. Decomposed by nitric acid with the separation of sulphur.

**Obs.**—Found principally in crystalline rocks, and its usual mineral associates are ores of silver, lead, and tin, also pyrite, chalcopyrite, and sphalerite. Occurs also in serpentine.

Abundant at Freiberg and Munzig, where it occurs in veins; at Reichenstein in Silesia, in serpentine; at Auerbach in Baden; in beds at Breitenbrunn and Raschau, Andreasberg, and Joachimsthal; at Tunaberg in Sweden; at Skutterud in Norway; at Wheal Maudlin and Unanimity, Cornwall, and at other localities; in Devonshire at the Tamar mines. In S. America, in the San Baldomero mine of Mt. Sorata in Bolivia, the arsenopyrite and danaite, the former having crystallized out of the latter and the most abundant ore; also both at Inquisivi in Bolivia; also, *niccoliferous* var., (anal. 23) between La Paz and Yungas in Bolivia; at many localities in New South Wales, sometimes highly auriferous.

In *New Hampshire*, in fine crystallizations in gneiss, at Franconia (*danaite*) associated with chalcopyrite; also at Jackson, and at Haverhill. In *Maine*, at Blue Hill, Corinna; Newfield (Bond's mountain), and Thomaston (Owl's Head). In *Vermont*, at Brookfield, Waterbury, and Stockbridge. In *Mass.*, at Worcester and Sterling. In *Conn.*, at Chatham, with smaltite and niccolite; at Monroe, with wolframite and pyrite; at Derby, in an old mine associated with quartz; at Mine Hill, Roxbury, in fine crystals with siderite. In *New Jersey*, at Franklin. In *N. York*, massive, in Lewis, ten miles south of Keeseville, Essex Co., with hornblende; in crystals and massive, near Edenville, on Hopkins's farm, and elsewhere in Orange Co., with scorodite, iron sinter, and thin scales of gypsum; also in fine crystals at two localities a few rods apart, four or five miles north-west of Carmel, near Brown's serpentine quarry in Kent, Putnam Co. In *California*, Nevada Co., Grass valley, at the Betsey mine, and also at Meadow lake, with gold, the *danaite* in crystals sometimes penetrated by gold.

In crystals at St. François, Beauce Co., Quebec; on Moulton Hill, near Lennoxville, Sherbrooke Co.; large beds occur in quartz ore veins at Deloro, Marmora Township, Hastings Co., Ontario, where it is mined for gold.

**Alt.**—Pseudomorphs consisting of pyrite.

**Ref.**—[1] Hohenstein, this variety is taken as fundamental because conforming most closely to the formula FeAsS, Zs. Kr., **2**, 434, 1878; cf. also, ib., **7**, 337, 1882; on the variation of angle in the cobaltiferous varieties, cf. Becke, Min. Mitth., 101, 1877, and earlier, Scheerer, Pogg., **42**, 546, 1837.

[2] See Hausm., Handb., **2**, 72, 1847; Mlr., Min., 188, 1852, and later Arzruni, l. c., and Gdt., Index, **1**, 256, 1886; Hausm. gives also (340), (370), (027). Miller's $x = 312$ is apparently a mistake for 321. [3] Gamper, Joachimsthal, Vh. G. Reichs., 354, 1876; cf. Arzruni, Zs. Kr., **1**, 396, 1877. [4] Magel, Auerbach, Ber. Oberhess. Ges., **22**, 297, 1882. [5] Schmidt, Servia, Földt. Közl., **17**, 557, 1887, and Zs. Kr., **14**, 573, 1888. [6] Magel, l. c., Bücking, Mitth. G. Land. Els. Lothr., **1**, 114. [7] Schrauf and Dana, Ber. Ak. Wien, **69** (1), 152, 1874.

The name mispickel is an old German term of doubtful origin. *Danaite* is from J. Freeman Dana of Boston (1793–1827), who first made known the Franconia locality.

CRUCITE (Crucilite) *Thomson*, Min., **1**, 435, 1836. Cruciform crystals, twins or trillings crossing at angles of 60° and 120°, disseminated in clay slate at Clonmell, county of Waterford, Ireland. They are red in color and consist largely of iron sesquioxide. They have been referred to staurolite (pseudomorphous), but Des Cloizeaux has shown that they are probably pseudomorphs after arsenopyrite (cf. f. 7, p. 98), Bull. Soc. Min. **11**, 63, 1888.

**99. SAFFLORITE.** *Breith.*, J. pr. Ch., **4**, 265, 1835. Faseriger Weisser Speiskobalt *Werner*. Grauer Speiskobalt, Arsenikkobalt *Rose*, Kr.-Ch. Min., 50, 1852. Eisenkobaltkies, Spathiopyrit, Der rhombische Arsenkobalteisen, Quirlkies *Sandberger*, Jb. Min., 410, 1868; 59, 1873; Ber. Ak. München, 135, 1873. Schlackenkobalt *Schneeberg miners*.

Orthorhombic. Form near that of arsenopyrite. Forms combinations of *m* (110, *I*) and a macrodome (*h*0*l*, *m*-ī), the latter brilliant in luster. Twins: tw. pl. *m*, probably in fivelings; also often in cruciform-twins crossing at angles of nearly 120° with tw. pl. probably (101) like marcasite and arsenopyrite. Also massive and with fibrous radiated structure.

Cleavage: *b* distinct. Fracture uneven. Brittle. H. = 4·5–5. G. = 6·9–7·3; 7·123–7·129 Breith. Luster metallic. Color tin-white, soon tarnishing to dark gray. Streak grayish black. Opaque.

**Comp.**—Like smaltite, essentially cobalt diarsenide, $CoAs_2$ = Arsenic 71·8, cobalt 28·2 = 100. Nickel and iron are also present in varying amounts, especially the latter. Compare remarks under smaltite.

**Anal.**—1, Varrentrapp, Pogg., **48**, 505, 1839. 2, Petersen, Jb., Min., 410, 1868. 3, Hofmann, Pogg., **25**, 485, 1832. 4, McCay, Am. J. Sc., **29**, 373, 1885. 5, Id., Inaug. Diss., p. 20, 1883. 6, Jäckel, Rose, Kr.-Ch. Min., 53, 1852. 7, McCay, ib., p. 21. 8, Van Gerichten, Ber. Ak. München, 138, 1873. 9, Kbl., Gründz. Min., 300, 1838.

In anal. 5, 5·82 quartz and 0·37 Bi have been deducted; also in 7, 1·24 Bi. McCay suggests that in anal. 9 the percentages of Co and Fe may have been exchanged, cf. anal. 4.

**Pyr.**—See smaltite.

**Obs.**—Occurs with smaltite, and implanted upon it, at Schneeberg in Saxony. Also similarly associated at Bieber near Hanau, in Hesse; at Wittichen in Baden; Tunaberg in Sweden.

Kenngott's *Einfach-Arsenik-Kobalt* from Bieber, supposed to be hexagonal in crystallization, is probably this species, Jb. Min., 754, 1869.

The name *safflorite* is from the German Safflor, *safflower, bastard saffron,* in allusion to its use. *Spathiopyrite* (from σπάθη) is the equivalent of the German *Quirtkies.*

The true position of safflorite was established by McCay, l. c.

**100. RAMMELSBERGITE.** Arseniknickel *Hofm.*, Pogg., **25**, 491, 1832. Weissnickelkies *Breith.*, Pogg., **64**, 184, 1845. Rammelsbergite *Dana*, Min., 61, 1854. [Not Rammelsbergite, Syn. of Chloanthite, *Haid.*, Handb., 1845.] Niguel blanco *Domeyko.*

Orthorhombic; *mm‴* = 56° to 57°. Crystals prismatic with a brachydome, resembling arsenopyrite. Also massive.

Cleavage: prismatic. Fracture uneven. Brittle. H. = 5·5–6. G. = 6·9–7·2; 7·099, 7·158 Breith. Luster metallic. Color tin-white with a tinge of red. Streak grayish black.

**Comp.**—Same as that of chloanthite, essentially nickel diarsenide, $NiAs_2$ = Arsenic 71·9, nickel 28·1 = 100. Cobalt and iron are present in small amount.

**Anal.**—1, Hofmann, l. c. 2, Hilger, Ber. Ak. München, 202, 1871. 3, McCay, Inaug. Diss., p. 8, 1883. Some of the analyses quoted under chloanthite may belong here; cf. p. 88.

| | | As | S | Ni | Co | Fe | Cu | Bi | |
|---|---|---|---|---|---|---|---|---|---|
| 1. Schneeberg | | 71·30 | 0·14 | 28·14 | — | — | 0·50 | 2·19 | = 102·27 |
| 2. " | G. = 7·19 | 68·30 | *tr.* | 26·65 | *tr.* | 2·06 | *tr.* | 2·66 | = 99·67 |
| 3. " | G. = 6·9 | 69·90 | 0·17 | 29·26 | 0·67 | *tr.* | — | | = 100 |

In 3, 5·11 p. c. bismuth have been deducted.

A mineral from Hüttenberg, referred here by Zepharovich, gave Weyde: As 60·40, S 5·20, Ni 13·37, Co 5·10, Fe 13·49 = 97·56. Vh. Min. Ges., 3, 90, 1868.

**Pyr.**—In the closed tube gives a sublimate of metallic arsenic; other reactions the same as with niccolite (p. 71).

**Obs.**—Occurs at Schneeberg and at Riechelsdorf. It was first separated from the isometric white nickel by Breithaupt.

Domeyko refers here a massive mineral from Portezuelo del Carrizo, Chili, 3 to 4 leagues from Morado, Department of Huasco.

**101. GLAUCODOT.** Glaukodot *Breith. & Plattn.*, Pogg., **77**, 127, 1849. Glaucodot. Kobalt arsenkies *pt.* Glaucodote. Akontit *Breith.*, J. pr. Ch., **4**, 258, 1835.

Orthorhombic. Axes $\breve{a} : \bar{b} : \dot{c}$ = 0·69416 : 1 : 1·1925 Lewis[1].

100 ∧ 110 = 34° 46′, 001 ∧ 101 = 59° 47¾′, 001 ∧ 011 = 50° 1′.

**Forms:**
*a* (100, *i*-ĭ)
*p* (610, *i*-6̄)[4]
*m* (110, *I*)
*e* (101, 1-ĭ)

**Pyr.**—In the closed tube gives a faint sublimate of arsenic trioxide. In the open tube sulphurous fumes and a sublimate of arsenic trioxide. B.B. on charcoal in R.F. gives off sulphur and arsenic, fusing to a feebly magnetic globule, which is black on the surface, but on the fracture has a light bronze color and a metallic luster. Treated with borax in R.F. until the globule has a bright metallic surface, the flux shows a strong reaction for iron; if the remaining globule is treated with a fresh portion of borax in O.F., the flux becomes colored smalt-blue from oxidized cobalt.

**Obs.**—Occurs in chlorite slate with cobaltite, in the province of Huasco, Chili. In fine crystals, often twins, with chalcopyrite and pyrite at Hakansbö, Sweden; this is probably the akontite of Breithaupt, cf. Lewis, l. c. The supposed glaucodot of Orawitza is alloclasite.

Named from *γλαυκός*, *blue*, because it is used for making smalt.

**Ref.**—[1] Hakansbö, Phil. Mag., **3**, 354. 1877. Becke obtained *mm‴* = 68° 4′ to 8½′, *ll‴* = 80° 7½′, and Sbk. *mm‴* = 69° 26′, *ll‴* = 80° 0′; cf. Min. Mitth., pp. 101, 353, 1877. [2] Mlr.. Huasco, Min., 190, 1852, gives *c*, *m*, *l*. [3] Tsch., Ber. Ak. Wien, **55** (1), 447, 1867. [4] Lewis, l. c. [5] Schrauf and Dana, Ber. Ak. Wien, **69** (1), 153, 1874.

**102. ALLOCLASITE.** Alloklas *Tschermak*, Ber. Ak. Wien, **53** (1), 220, 1866. Glaucodot pt. *Breith.*

Orthorhombic. Rarely in crystals, with *mm‴* = 74°, *ee′* = 58° (*e* = 101, 1-ĭ). Commonly in columnar to hemispherical aggregates.

Cleavage: *m* perfect; *c* distinct. H. = 4·5. G. = 6·6. Color steel-gray. Streak nearly black.

**Comp.**—Probably essentially $Co(As,Bi)S$ with cobalt in part replaced by iron; that is, a glaucodot containing bismuth.

**Anal.**—1–6, Frenzel, Min. Mitth., **5**, 181, 1883. Also 5th Ed., p. 81.

| | As | Bi | S | Co | Fe | Cu |
|---|---|---|---|---|---|---|
| 1. | 33·04 | 25·99 | 18·21 | 21·06 | 3·54 | 0·20 = 102·04 |

| 6. | 28·22 | 32·83 | 16·06 | 20·25 | 2·71 | 0·22 = 100·29 |

The mechanically mixed gold has been deducted, viz.: 1·24, 1·10, 1·10, 1·20, 1·10, 1·70 p. c. respectively.

**Pyr., etc.**—B.B. on charcoal gives arsenical fumes, and a bismuth coating. Fuses to a dull globule. Soluble in nitric acid.

**Obs.**—Occurs at Orawitza, Hungary.

Named from *ἄλλος*, *κλάειν*, *to break*, because its cleavage was believed to differ from that of arsenopyrite and marcasite, which it resembles.

**103. WOLFACHITE.** *F. Sandberger*, Jb. Min., 313, 1869.

Orthorhombic. In small crystals with *m* (110, *I*), and *x* (0*kl*, *m*-ĭ) and sometimes *b* (010, *i*-ĭ), resembling arsenopyrite. Also in columnar radiated aggregates.

Brittle. Fracture uneven. H. = 4·5–5. G. = 6·372. Luster metallic. Color silver-white to tin-white. Streak black.

**Comp.**—Probably $Ni(As,Sb)S$, near corynite.

**Anal.**—Petersen, Pogg., **137**, 397, 1869.

Twins: tw. pl. 𝔪, (1) as contact twins; (2) sometimes as twinned lamellæ; (3) as penetration-twins giving rise to branching arborescent forms resembling written characters and crossing at an angle of 69° 44′, rarely 55° 8′ as too 90°. Crystals in part nearly orthorhombic in symmetry, with *a*, or 𝔪, or *a* and *b* predominating; again monoclinic and usually with 𝔪 or *a* largely developed; *σ* also sometimes prominent. Skeleton forms common. Also bladed and imperfectly columnar to granular.

Cleavage: *b* perfect. Fracture uneven. Brittle. H. = 1·5–2. G. = 7·9–8·3. Luster metallic, brilliant. Color and streak pure steel-gray to silver-white, inclining to yellow.

**Comp.**—Telluride of gold and silver $(Au,Ag)Te_2$ with Au : Ag = 1 : 1; this requires: Tellurium 62·1, gold 24·5, silver 13·4 = 100.

**Pyr., etc.**—In the open tube gives a white sublimate of tellurium dioxide which near the assay is gray; when treated with the blowpipe flame the sublimate fuses to clear transparent drops. B.B. on charcoal fuses to a dark gray globule, covering the coal with a white coating, which treated in R.F. disappears, giving a bluish green color to the flame; after long blowing a yellow, malleable metallic globule is obtained. Most varieties give a faint coating of lead oxide and antimony trioxide on charcoal.

**Obs.**—With gold, at Offenbánya in Transylvania, in narrow veins, which traverse porphyry; also at Nagyág. In California, Calaveras Co., at the Melones and Stanislaus mines. In Boulder Co., Colorado, at the Red Cloud, Grand View and Smuggler mines; also associated with tetrahedrite near Lake City.

Named from Transylvania, the country in which it was first found, and in allusion to *sylvanium*, one of the names at first proposed for the metal tellurium. Called *graphic* because of a resemblance in the arrangement of the crystals to writing characters.

**Ref.**—[1] Zs. Kr., **2**, 211, 1878. Early made orthorhombic (Miller) but shown to be monoclinic by Koksharov. [2] From Schrauf, l. c., whom see for a careful discussion of earlier results and literature. See also Mlr., Min., 134, 1852. Kk., Bull. Ac. St. Pet., **6**, 192, 1865, or Vh. Min. Ges., **1**, 6, 1866; also Min. Russl., **10**, 165, 1889.

MÜLLÉRINE *Beud.*, Tr., **2**, 541, 1832. Gelberz *Karsten*, Tab., 56, 1800. Weisstellur, Weisserz, *Petz*, Pogg., **57**, 473, 1842. A white to brass-yellow telluride from Nagyág, occurring in bladed foliated forms, cleavable and massive. Analyses have shown the presence of antimony and lead, in part due to impurities, and it has been formerly referred with a question to sylvanite. Krenner and Schrauf make it identical with krennerite, see references under these species.

| 4. | " | G. = 9·043 | 57·32 | 38·75 | 3·03 = 99·10 |

**Pyr., etc.**—B.B. on charcoal fuses with a bluish green flame, yielding globules of very yellow gold. Dissolves in aqua regia, with separation of silver chloride.

Occurs with petzite at the Stanislaus mine, Calaveras county, California. Also at the Red Cloud mine, Colorado, with sylvanite and quartz; and at the Keystone and Mountain Lion mines.

Calaverite has the same general formula as sylvanite but a much higher percentage of gold, and may belong with it; or if anal. 2 of krennerite expresses its true composition, it may be the crystallized form of calaverite.

**106. NAGYAGITE.** Aurum Galena, Ferro et particulis volatilibus mineralisatum, *Scopoli*, Ann. Hist. Nat., **3**, 107; *v. Born*, Lithoph., **1**, 68, 1772. Nagiakererz *Wern.* Bergm. J., 1789. Schrauf.

**Pyr.**, etc.—In the open tube gives, near the assay, a grayish sublimate of antimonate and tellurate, with perhaps some sulphate of lead; farther up the tube the sublimate consists of antimony trioxide, which volatilizes when treated with the flame, and tellurium dioxide, which at a high temperature fuses into colorless drops. B.B. on charcoal forms two coatings: one white and volatile, consisting of a mixture of antimonate, tellurate, and sulphate of lead; and the other yellow, less volatile, of lead oxide quite near the assay. If the mineral is treated for some time in O.F. a malleable globule of gold remains; this cupelled with a little assay lead assumes a pure gold color. Decomposed by aqua regia.

**Obs.**—At Nagyág in Transylvania, in foliated masses and crystalline plates, accompanying rhodonite, sphalerite, and gold; and at Offenbánya associated with antimonial ores. Reported from Colorado with other tellurides.

Berthier has analyzed another ore, very similar to the above in physical characters, consisting of: Tellurium 13·0, sulphur 11·7, lead 63·1, gold 6·7, antimony 4·5, copper 1·0 = 100. It is called *Blatterine* (Blätterin, Blättererz *Germ.*) by Huot, Min., **1**, 189, 1841.

**Ref.**—[1] Zs. Kr., **2**, 239, 1878, earlier regarded as tetragonal, to which it closely approximates; cf. also Fletcher, Phil. Mag., **9**, 188, 1880.

SILBERPHYLLINGLANZ *Breith.*, Schw. J., **1**, 178, 1828. Nobilite *Adam*, Tabl. Min., 35, 1869. Occurs in gneiss at Deutsch-Pilsen, Hungary, appears to be related to nagyagite Color blackish gray. Structure foliated massive. One perfect cleavage. H. = 1·2. G. = 5·8–5·9.

According to Plattner (Probirkunst, 3d Ed., 421) the constituents are: antimony, lead, tellurium, gold, silver, and sulphur—4·9 p. c. of gold, 0·3 of silver—the sulphur probably in combination with the antimony and lead. Only a trace of selenium was found, contrary to the earlier determinations of Harkort and Breithaupt.

Kermesite *Chapman*, Min., 61, 1843. Pyrostibit *Glock.*, Syn., 16, 1847. Pyrantimonite *Breith.* Antimonio rosso *Ital.* Antimonio rojo *Span.*

Monoclinic. Axes $\grave{a} : \acute{c} = 1 : 1{\cdot}4791$; $\beta = {}^{*}77° \, 51' = 001 \wedge 100$ Kenngott[1].

**Forms:** *a* (100, *i-ī*, *p*), *c* (001, *O*, *u*), *s* ($\bar{1}03$, $\frac{1}{3}$-$\bar{\imath}$), *o* ($\bar{1}01$, 1-$\bar{\imath}$).
Angles: *cs* = 28° 16′, *co* = 64° 32′, *a′o* = *37° 37′.

Usually in tufts of capillary crystals, prismatic ‖ orthodiagonal.

Cleavage: *a* perfect. Sectile; thin leaves slightly flexible. H. = 1–1·5. G. = 4·5–4·6. Luster adamantine, inclining to metallic. Color cherry-red. Streak brownish red. Feebly translucent.

**Comp.**—Antimony oxysulphide, $Sb_2S_2O$ or $2Sb_2S_3.Sb_2O_3$ = Antimony trisulphide 70·0, antimony trioxide 30·0 = 100; or antimony 75·0, sulphur 20·0, oxygen 5·0 = 100. Analyses, Rose, 5th Ed., p. 187.

**Pyr., etc.**—In the closed tube blackens, fuses, and at first gives a white sublimate of antimony trioxide; with strong heat gives a black or dark-red sublimate. In the open tube and on charcoal reacts like stibnite.

**Obs.**—Results from the alteration of stibnite. Occurs in veins in quartz, accompanying stibnite and valentinite at Malaczka near Posing in Hungary; at Bräunsdorf near Freiberg in Saxony; at Allemont in Dauphiné; at New Cumnock in Ayrshire, Scotland.

At South Ham, Wolfe Co., Quebec, Canada; in cavities in native antimony and stibnite at the Prince William mine, York Co., New Brunswick.

The *tinder ore* (*Zundererz*) has been shown to be wholly distinct from red antimony.

Named from *kermes*, a name given (from the Persian *qurmizq*, crimson) in the older chemistry to red amorphous antimony trisulphide, often mixed with antimony trioxide.

**Ref.**—[1] Min. Unt., **1**, 1, 1849, Breslau; cf. Mohs, Min., **2**, 598, 1824.

In implanted spherical globules; structure thin curved lamellar.

H. = 4–4·5. G. = 3·66–3·80. Luster vitreous to greasy; or pearly on a cleavage surface. Color dirty rose-red, yellowish, brownish. Opaque or subtranslucent. Optically uniaxial, positive.

**Comp.**—Zinc oxysulphide, $Zn_5S_4O$ or $4ZnS.ZnO$ = Zinc sulphide 82·7, zinc oxide 17·3 = 100.

**Anal.**—1, Fournet, l. c. 2, Lindaker, Vogl's Min. Joach., 175.

| | | ZnS | ZnO | $Fe_2O_3$ |
|---|---|---|---|---|
| 1. Rosières | G. = 3·66 | 82·82 | 15·34 | 1·84 = 100 |
| 2. Joachimsthal | | 82·75 | 17·25 | — = 100 |

**Pyr., etc.**—B.B. like sphalerite. In hydrochloric acid affords fumes of hydrogen sulphide.

**Obs.**—Occurs at Rosières, near Pont Gibaud, in Puy de Dôme; Elias mine near Joachimsthal, with galena, sphalerite, native bismuth, etc.; near Marienberg (the *leberblende*); Hochmuth near Geyer; at Bernkastel on the Mosel, in pseudomorphs after quartz; Cornwall, probably at Redruth.

Named after the French mining engineer, Voltz.

Supposed artificial voltzite from the Freiberg smelting-works has been shown to be sphalerite.

## Appendix to Sulphides, etc.

**Arsenotellurite.** *Hannay* J. Ch. Soc., **26**, 989, 1873. A supposed new telluride. Stated to occur in small brownish scales upon arsenical iron-pyrites. Analysis: Te 40·71, As 23·61, S 35·81 = 100·13. No locality given.

**Bolivianite.** Bolivian *Breith.*, B. H. Ztg., **25**, 188, 1866. Orthorhombic. In acicular rhombic prisms, tufts, and fine columnar. Resembles stibnite. H. = 2·5. G. = 4·820–4·828. Cleavage: brachydiagonal distinct. Luster submetallic. Color lead-gray, a little darker than in stibnite. According to T. Richter, an antimonial silver sulphide containing 8·5 p. c. of silver. From Bolivia.

**Kaneite.** *R. J. Kane*, Q. J. Sci., **28**, 381, 1829; *Haid.*, Handb. 559, 1845. Arsenikmangan. Described as a manganese arsenide ($MnAs$) occurring in botryoidal, granular masses attached to galena. G. = 5·55. Color grayish white, tarnishing black. Luster metallic. Supposed to be from Saxony. Needs confirmation.

**Plakodin.** *Breithaupt*, Pogg., **53**, 631, 1841. Plattner, ib., 58, 283, 1843. Placodine. A supposed nickel arsenide ($NiAs_2$) in monoclinic tabular crystals. Stated by Breithaupt to occur at Müsen, near Siegen, with siderite and gersdorffite, but probably only a furnace product. Cf. Schnabel, Pogg., **84**, 585, 1851; Rose, Kr.-Ch. Min., 47, 1852. Dana, Min., 3d Ed., 475, 1850.

**Plumbomanganite.** *Hannay*, Min. Mag., **1**, 151, 1877. Massive, crystalline. G. = 4·01. Color dark steel-gray, with a bronze tinge when exposed to the air for some time. Analysis: Mn 49·00, Pb 30·68, S 20·73 = 100·41. Of unknown source.

**Plumbostannite.** *A. Raimondi*, Minéraux du Pérou, p. 187, 1878.

Amorphous; structure granular. H. = 2. Feel greasy, like graphite. Slightly ductile. Luster feebly metallic. Color gray. Analysis (deducting 38·8 p. c. quartz):

G. = 4·5 S 25·14 Sb 16·98 Sn 16·30 Pb 30·66 Fe 10·18 Zn 0·74 = 100

B.B. gives on charcoal antimonial fumes and a lead coating: yields metallic tin. Dissolves completely in hydrochloric acid to which a little nitric acid has been added. With concentrated nitric acid leaves a white residue of the oxides of tin and antimony and lead sulphate.

From the district of Moho, province of Huancané, Peru; occurs with cassiterite and sphalerite.

**Sulphide of Copper and Silver.** A massive mineral from the Gagnon mine, near Butte, Montana. resembling bornite has been described by R. Pearce. H. = 3·5–4. G. = 4·95. Analysis: S 20·51, Cu 41·10, Ag 24·66, Zn 9·80, Fe 2·09, insol. 1·02 = 99·18. This conforms to $3Cu_2S.Ag_2S.2ZnS$. Col. Sc. Soc., **2**, 70, 1887. Hillebrand obtained for the same mineral: S 20·88, Cu 40·24, Ag 21·80, Zn 12·83, Fe 1·98, Pb 1·46 = 99·19. G. = 5·407. Ibid., **3**, 45, 1888. It is not certain that the mineral was homogeneous. Cf. jalpaite, p. 47; castillite, p. 78.

Another ore from Idaho Springs, Col., is regarded by Pearce as a mixture of bornite and stromeyerite (ibid., p. 188); it gave: S 19·40, Cu 42·49, Ag 26·31, Fe 6·22, Pb, insol. *undet.* = 94·42.

**Valleriite.** *Blomstrand*, Öfv. Ak. Stockh., **27**, 19, 1870. A massive metallic mineral resembling pyrrhotite in color; very soft. Contains sulphur, copper, iron, alumina, magnesia, and water. Of doubtful purity. Found sparingly at the Aurora mine, Nya-Kopparberg, Sweden. Named for the Swedish mineralogist Vallerius. For analyses see 5th Ed., App. II., p. 58, 1875.

**Youngite.** *Hannay*, Min. Mag., **1**, 152, 1877; **2**, 88, 1878. A metallic mineral of doubtful homogeneity, containing sulphur, lead, zinc, iron, and manganese. One specimen analyzed was of unknown source, another from Ballarat, Australia. For analyses, etc., see 5th Ed., App. III., p. 133, 1882.

# III. SULPHO-SALTS.

## I. Sulpharsenites, Sulphantimonites, Sulphobismuthites.

## II. Sulpharsenates, etc.

The species here included are chiefly salts of the sulpho-acids of trivalent arsenic, antimony and bismuth. The most important acids are the ortho-acids, $H_3AsS_3$, etc., and the meta-acids, $H_2AsS_2$, etc.; but $H_4As_2S_5$, etc., and a series of others are included. A smaller section includes the sulpharsenates, etc., chiefly normal salts of the acid $H_3AsS_4$, analogous to $H_3AsO_4$. The metals present as bases are chiefly copper, silver, lead; also, iron, zinc, mercury, rarely others (as Ni,Co) in small amount. In view of the hypothetical character of many of the acids whose salts are here represented, there is a certain advantage, for the sake of comparison, in writing the composition after the dualistic method, $RS.As_2S_3$, $2RS.As_2S_3$, etc.

---

## I. Sulpharsenites, Sulphantimonites, etc.

### A. Acidic Division.

| | | |
|---|---|---|
| 109. | **Livingstonite** | $HgS.2Sb_2S_3$ |
| 110. | **Guejarite** | $Cu_2S.2Sb_2S_3$ Orthorhombic $\breve{a} : \bar{b} : \acute{c} = 0{\cdot}8221 : 1 : 0{\cdot}7841$ |
| 111. | **Chiviatite** | $2PbS.3Bi_2S_3$ |
| 112. | **Cuprobismutite** | $3Cu_2S.4Bi_2S_3$ |
| 113. | **Rezbanyite** | $4PbS.5Bi_2S_3$ |

**109. LIVINGSTONITE.** *Mariano Barcèna*, Naturaleza, 3, 35, 172, 1874. Am. J. Sc., **8**, 145, 1874; **9**, 64, 1875.

In groups of slender prismatic crystals; also columnar massive, resembling stibnite.

H. = 2. G. = 4·81. Luster metallic. Color bright lead-gray. Streak red. Opaque.

**Comp.**—$HgSb_4S_7$ or $HgS.2Sb_2S_3$ = Sulphur 22·1, antimony 53·1, mercury 24·8 = 100.

**Anal.**—1, Barcena, l. c. 2, Id., Naturaleza, **4**, 268, 1879. 3, Venable, Chem. News, **40**, 186, 1879. 4, Page, ib., **42**, 195, 1880.

| | S | Sb | Hg | |
|---|---|---|---|---|
| 1. Huitzuco | 29·08 | 53·12 | 14·00 | Fe 3·50 = 99·70 |
| 2. " | 22·97 | 53·12 | 20·00 | gangue and loss 3·91 = 100 |
| 3. " | $\frac{2}{2}$ 23·73 | 53·75 | 22·52 | = 100 |
| 4. Guadalcazar | 24·50 | 52·21 | 22·61 | Fe 0·68 = 100 |

The results under (3) and (4) have been obtained by recalculation, after deducting impurities (chiefly gypsum, free sulphur, insol. residue), viz. in (3), 13 to 16 p. c., in (4), 37·6 p. c. Groth suggests that the formula may more properly be written $Hg_2S.4Sb_2S_3$ = Sulphur 21·9, antimony 57·0, mercury 21·1 = 100.

**Pyr.**, etc.—B.B. very fusible, giving off white antimonial fumes freely. Yield's metallic mercury in the open tube, or in the closed tube with soda. Not sensibly attacked by cold nitric acid, but dissolved by warm acid, with the separation of antimony trioxide.

**Obs.**—Occurs at Huitzuco, State of Guerrero, Mexico, in a matrix of calcite and gypsum with sulphur, cinnabar, stibnite, and valentinite. Also at Guadalcazar, in San Luis Potosi, with gypsum, sulphur, etc.

Named after David Livingstone (1813–1873), the African explorer and missionary.

**Alt.**—Page (l. c.) gives an analysis of an ill-defined alteration product of livingstonite.

**Artif.**—Baker, by fusing together HgS and $Sb_2S_3$ in an atmosphere of $CO_2$ has obtained a crystalline mass resembling livingstonite and yielding on analysis: S 24·83, Sb 53·20, Hg 22·71 = 100·74. Chem. News, **42**, 196, 1880.

**110. GUEJARITE.** *Cumenge*, Bull. Soc. Min., **2**, 201, 1879.

Orthorhombic. Axes $\breve{a} : \bar{b} : \dot{c}$ = 0·8221 : 1 : 0·7841 Friedel[1].

$100 \wedge 110 = 39° 25\frac{1}{2}'$, $001 \wedge 101 = 43° 39'$, $001 \wedge 011 = 38° 6'$.

**Forms:** *b* (010, *i*-ĭ), *c* (001, *O*); *h* (210, *i*-$\bar{2}$), *k* (320, *i*-$\frac{3}{2}$)[2]?, *m* (110, *I*), *l* (230, *i*-$\frac{3}{2}$)[2]?; *d* (013, $\frac{1}{3}$-ĭ), *e* (011, 1-ĭ). Also doubtful 410, 310, 032, and two pyramids *x*, *z*, with *bx* = 56° 24′, *bz* = 39° 58′.

Angles: *hh‴* = 44° 41′, *bh* = *67° 39$\frac{1}{3}$′, *kk‴* = 57° 27′, *mm‴* = 78° 51′, *ll′* = 78° 5′; *dd′* = 29° 18′, *ee′* = 76° 12′, *be* = *51° 54′.

In prismatic crystals, flattened ∥ *b*.

Cleavage: *b* nearly perfect. Brittle. H. = 3·5. G. = 5·03. Luster metallic. Color steel-gray, with a tinge of blue. Streak black. Opaque.

**Comp.**—$Cu_2Sb_4S_7$ or $Cu_2S.2Sb_2S_3$ = Sulphur 27·0, antimony 57·8, copper 15·2 = 100.

**Anal.**—Cumenge, l. c.

S 25·0 Sb 58·5 Cu 15·5 Fe 0·5 Pb *tr.* = 99·5

**Pyr.**—B.B. on charcoal gives off antimonial fumes, and yields metallic copper when treated with soda.

**Obs.**—Occurs with siderite at the copper mines at the foot of Muley-Hacen, in the district of Guejar, Sierra Nevada, Andalusia.

**Ref.**—[1] Bull. Soc. Min., **2**, 203, 1879. [2] Given as (730) and (370) which correspond with the angles less well than these, which, however, are only approximate.

**111. CHIVIATITE.** Chiviatit *Rammelsberg*, Pogg., **88**, 320, 1853.

Foliated massive; resembling bismuthinite.

Cleavage in three directions in one zone, one making an angle with the second of 27°, and with the third of 47°, Mlr. G. = 6·920. Luster metallic. Color lead-gray.

**Comp.**—$Pb_2Bi_6S_{11}$ or $2PbS.3Bi_2S_3$=Sulphur 17·5, bismuth 61·9, lead 20·6=100. Part of the lead is replaced by copper.

**Anal.**—Rammelsberg, l. c.

| S | Bi | Pb | Cu | Fe | Ag | insol. |
|---|---|---|---|---|---|---|
| 18·00 | 60·95 | 16·73 | 2·42 | 1·02 | *tr.* | 0·59 = 99·71 |

**Pyr.**—Same as for aikinite, Rg.

**Obs.**—From Chiviato, in Peru, with pyrite and barite.

**112. CUPROBISMUTITE.** Sulphobismuthite of copper and silver *Hillebrand*, Am. J. Sc., **27**, 355, 1884. Kupfersulfobismutit *Brezina*. Cuprobismutite *Dana*.

In groups of slender prismatic crystals, deeply striated longitudinally and resembling bismuthinite; also compact.

G. = 6·31–6·68. Luster metallic. Color dark bluish black. Streak black. Opaque.

**Comp.**—Probably $Cu_6Bi_8S_{16}$ or $3Cu_2S.4Bi_2S_3$ = Sulphur 19·1, bismuth 65·9, copper 15·0 = 100. The copper is sometimes in part replaced by silver.

**Anal.**—1–3, Hillebrand, l. c.

| | S | Bi | Cu | Ag | Pb | Fe | Zn |
|---|---|---|---|---|---|---|---|
| 1. Missouri Mine | 19·94[a] | 60·80 | 15·96 | 0·89 | — | 2·13 | 0·10 = 99·82 |
| 2. " | 18·83[a] | 63·42 | 12·65 | 4·09 | — | 0·59 | 0·07 = 99·65 |
| 3. Missouri Mine? | 17·90 | 62·51 | 6·68 | 9·89 | 2·74 | 0·10 | 0·07 = 99·89 |

[a] Calculated.

From (1) 4·43 p. c. gangue have been deducted; from (2) 59·75 p. c.; from (3) 47·57 p. c. There remain in (1) 6·97 chalcopyrite; in (2) 1·91 p. c.; in (3) 0·33 p. c.; also a little sphalerite. Deducting these the ratio of $R_2$ : Bi : S corresponds to 3 : 8 : 15.

**Pyr., etc.**—In the closed tube a sublimate of sulphur; a bismuth coating on charcoal; soluble in acids.

**Obs.**—Occurs in a quartz gangue associated with chalcopyrite and wolframite at the Missouri mine, Hall's Valley, Park Co., Colorado; the ore is auriferous, sometimes highly so.

DOGNACSKAITE Földt. Közl., **14**, 564, 1884. Briefly mentioned by Krenner as a "Wismuthkupfererz" with the following characters:

Cleavage in one direction; color gray, tarnishing on exposure to the air. Analysis by Maderspach:

S 15·75 Bi 71·79 Cu 12·28 = 99·82

Occurs at Dognácska, Hungary, with gold, pyrite, chalcocite, and bismuth ocher.

**113. REZBANYITE** *A. Frenzel*, Min. Mitth., 5, 175, 1883.

Massive; fine granular to compact.

Cleavage indistinct. H. = 2·5–3. G. = 6·09–6·38. Luster metallic. Color light lead-gray, becoming darker. Streak black. Opaque.

**Comp.**—$Pb_4Bi_{10}S_{19}$ or $4PbS.5Bi_2S_3$=Sulphur 17·3, bismuth 59·1, lead 23·6=100.

**Anal.**—1–3, Frenzel, l. c.

| | S | Bi | Pb | Ag | Cu | Zn |
|---|---|---|---|---|---|---|
| 1. | 17·85 | 59·08 | 19·80 | 1·89 | 1·71 | *tr.* = 100·33 |
| 2. | 16·61 | 62·57 | 15·10 | 1·89 | 3·71 | 0·12 = 100 |
| 3. | 16·89 | 62·88 | 13·88 | 2·46 | 3·77 | 0·12 = 100 |

The above results obtained after the deduction of chalcopyrite: in (1) 4·64 p. c., in (2) 3·63, in (3) 6·58; also calcite in (1) 5·00 p. c., in (2) [4·72], in (3) [4·08].

**Obs.**—Occurs at Rezbanya, Hungary, intimately mixed with chalcopyrite and calcite; also embedded in quartz. Named from the locality. The same name was given by Hermann to a lead-gray bismuth ore from Rezbanya, which was probably an impure cosalite, cf. p. 121.

**Pyr.**—Like galenobismutite.

## B. Meta-Division. $RAs_2S_4$, $RSb_2S_4$, $RBi_2S_4$.

### Zinkenite Group. $RS.(As,Sb,Bi)_2S_3$. Orthorhombic.

| | | | $\breve{a} : \bar{b} : \acute{c}$ |
|---|---|---|---|
| **114.** | **Zinkenite** | $PbS.Sb_2S_3$ | 0·5575 : 1 : 0·6353 |

## Zinkenite Group.

**114. ZINKENITE.** Zinkenit *G. Rose*, Pogg., **7**, 91, 1826. Bleiantimonglanz *Groth*, Tab. Ueb., 25, 1882. Zinckenit.

Orthorhombic. Axes $\breve{a} : \bar{b} : \dot{c}$ = 0·5575 : 1 : 0·6353 Rose[1].
100 ∧ 110 = 29° 8⅓′, 001 ∧ 101 = 48° 44′, 001 ∧ 011 = 32° 25⅔′.

**Forms**: ϵ (102, ½-ī), *k* (061, 6-ĭ). Angles: ϵϵ′ = *59° 21′, *kk′* = *150° 36′.

Crystals seldom distinct; sometimes in nearly hexagonal forms through twinning. Lateral faces longitudinally striated. Also columnar, fibrous, massive.

Cleavage not distinct. Fracture slightly uneven. H.=3–3·5. G.=5·30–5·35. Luster metallic. Color and streak steel-gray. Opaque.

**Comp.**—$PbSb_2S_4$ or $PbS.Sb_2S_3$ = Sulphur 22·3, antimony 41·8, lead 35·9 = 100. Arsenic sometimes replaces part of the antimony.

**Anal.**—1, H. Rose, Pogg., **8**, 99, 1826. 2, Kerl B. H. Ztg., **12**, 20, 1853. 3, Hilger, Lieb. Ann., **185**, 205, 1877. 4, W. F. Hillebrand, Proc. Col. Soc., **1**, 121, 1884.

| | | S | Sb | Pb | |

| 3. Kinzigthal | | 23·04 | 46·18 | 30·80 | = 100·02 |
| 4. Red Mt., Col. | G. = 5·21 | 22·50 | 35·00 | 32·77 | As 5·64, Cu 1·20, Ag 0·23, gangue, etc., 1·37 [= 98·71 |

**Pyr., etc.**—Decrepitates and fuses very easily; in the closed tube gives a faint sublimate of sulphur, and antimony trisulphide. In the open tube sulphurous fumes and a white sublimate of antimony trioxide; the arsenical variety gives also arsenical fumes. On charcoal is almost entirely volatilized, giving a coating which on the outer edge is white, and near the assay dark yellow; with soda in R.F. yields globules of lead.

Soluble in hot hydrochloric acid with evolution of hydrogen sulphide and separation of lead chloride on cooling.

**Obs.**—Occurs in the antimony mine of Wolfsberg in the Harz; the groups of columnar crystals occur on a massive variety in quartz; the crystals sometimes over half an inch long and two or three lines broad, frequently extremely thin and forming fibrous masses. From the Ludwig mine, Adlerbach near Hausach, Kinzigthal, Baden. Pontgibaud, Puy de Dôme, France. In the U. S., at the antimony mines of Sevier County, Arkansas; in Colorado at the Brobdignag mine, Red mountain, San Juan Co.

Named after J. K. L. Zinken (1798–1862), director of the Anhalt mines (also written Zincken).

**Ref.**—[1] l. c. Kenng., Ber. Ak. Wien, **9**, 1852.

Crystals slender, elongated ‖ axis b̄; also striated or channeled in this direction.

Cleavage: c distinct. Fracture conchoidal. Very brittle. H. = 3. G. = 5·393. Luster metallic. Color dark lead-gray. Streak reddish brown. Opaque.

**Comp.**—$PbAs_2S_4$ or $PbS.As_2S_3$ = Sulphur 26·4, arsenic 31·0, lead 42·9 = 100.

**Anal.**—Uhrlaub, Pogg., **94**, 124, 1855. Other analyses, 5th Ed., p. 87.

| S | As | Pb | Ag | Fe |
|---|---|---|---|---|
| 25·91 | 28·56 | 44·56 | 0·42 | 0·45 = 99·90 |

The excess of lead is probably due to admixed dufrenoysite.

**Pyr., etc.**—Nearly the same as for dufrenoysite, but differing in strong decrepitation.

**Obs.**—From the Binnenthal with dufrenoysite and binnite.

Named after Sartorius v. Waltershausen (1809–1876) who first announced the species; *scleroclase* is from σκληρός, *hard, violent*, and κλάειν, *to break*, in allusion to its brittle character.

**Ref.**—[1] Pogg., **122**, 380, 1864; see earlier (l. c.) Heusser, Dx. and Mgc., but note Rath's criticism of Dx. (l. c. p. 392 *et al.*), whose determinations were made in part on crystals of jordanite. [2] Cf. Rath, l. c.; the symbols of some of the macrodomes need confirmation; the measurements of earlier observers (see above) add other planes in the two series of domes, but mostly of doubtful position.

**116. EMPLECTITE.** Wismuth-Kupfererz (fr. Tannenbaum) *Selb*, Tasch. Min., **11**, 441, 451, 1817. Kupferwismuthglanz *R. Schneider*, Pogg., **90**, 166, 1853. Emplektit *Kenng.*, Ueb., 125, 1853. Tannenite *Dana*, Min., 73, 1854. Hemichalcit *Kbl.*, Gesch. Min., 600, 1864.

Orthorhombic. Axes: ă : b̄ : ċ = 0·5430 : 1 : 0·6256 Weisbach[1].

100 ∧ 110 = 28° 30$\frac{1}{6}$′, 001 ∧ 101 = 49° 2$\frac{1}{2}$′, 001 ∧ 011 = 32° 1$\frac{5}{6}$′.

**Forms:** b (010, i-ĭ) u (509, $\frac{5}{9}$-ī) z (506, $\frac{5}{6}$-ī) x (501, 5-ī) k (061, 6-ĭ)
a (100, i-ī) c (001, O) g (507, $\frac{5}{7}$-ī) y (503, $\frac{5}{3}$-ī) d (021, 2-ĭ)

Angles: *uu′* = 65° 15′, *gg′* = 79° 2′, *zz′* = 87° 40′, *yy′* = 124° 59′, *xx′* = 160° 18′, *dd′* = 102° 44′, *kk′* = 150° 10′, *cz* = *43° 50′, *kc* = *75° 5′.

In thin striated prisms, elongated ‖ b̄.

Cleavage: c perfect; b less so; also z (?) distinct. Fracture conchoidal to uneven. Brittle. H. = 2. G. = 6·3–6·5. Luster metallic. Color grayish to tin-white. Opaque.

**Comp.**—$CuBiS_2$ or $Cu_2S.Bi_2S_3$ = Sulphur 19·1, bismuth 62·0, copper 18·9 = 100.

**Anal.**—1, Schneider, Pogg., **90**, 166, 1863. 2, Petersen, Jb. Min., 847, 1869. 3, Daw, Ch. News, **40**, 225, 1879. 4, Loczka, Földt. Közl., **14**, 564, 1884.

**Pyr., etc.**—In the open tube gives sulphurous fumes. B.B. on charcoal fuses easily, with frothing and spirting; treated with soda coats the coal dark yellow from bismuth oxide, and gives a globule of copper. Decomposed by nitric acid, with separation of sulphur.

**Obs.**—Occurs embedded in quartz at the mines of Tannenbaum, near Schwarzenberg, also near Pöhla, and on the Schreckenberg at Annaberg, Saxony. At Christophsau near Freudenstadt, Würtemberg; Rezbanya, Hungary. At the Aamdal copper mines, Telemarken, Norway. From Cerro Blanco in Copiapo, Chili.

Named from ἐμπλεκτος, *entwined, interwoven*, in allusion to its intimate association with quartz.

**Artif.**—Obtained by Schneider, J. pr. Ch., **40**, 564, 1889.

**Ref.**—[1] Pogg., **128**, 435, 1866; see also Dbr., ib., **92**, 241, 1854.

| 2. Guadiz | G. = 5·015 | 25·29 | 48·30 | 25·36 | 1·23 | — | = 100·18 |

The iron is supposed to exist as pyrite, and the lead as jamesonite.

**Pyr., etc.**—In the closed tube decrepitates at first, and then fuses, giving a faint sublimate of antimony trisulphide, which on cooling is dark red; in the open tube gives sulphurous and antimonial fumes, the latter forming a white sublimate. B.B. on charcoal fuses to a globule, emitting antimonial fumes, coating the coal white; the globule treated with borax reacts for iron; with soda gives a globule of metallic copper.

Decomposed by nitric acid, with separation of sulphur and antimony trioxide.

**Obs.**—From Wolfsberg in the Harz, in nests embedded in quartz; and at Guadiz, Spain. It is usually covered with a coating of pyrite. Glocker's name antedates Nicol's. *Rosite* has an earlier use.

**Ref.**—[1] Pogg., **35**, 360, 1835. See also p. 1030.

**118. GALENOBISMUTITE.** *H. Sjögren*, G. För. Förh., **4**, 109, 1878. Alaskaite *Koenig*, Am. Phil. Soc., 472, 1881. Bleiwismuthglanz *Groth*, Tab. Ueb., 25, 1882. Selenbleiwismuthglanz *Id.*, Tab. Ueb., 28, 1889.

Crystalline, columnar with indistinct faces; also massive, foliated or radiated to compact.

H. = 3–4. G. = 6·88; 7·145 Falun. Luster metallic. Color dark to light lead-gray to tin-white. Streak grayish black. Opaque.

**Comp., Var.**—$PbBi_2S_4$ or $PbS.Bi_2S_3$ = Sulphur 17·1, bismuth 55·4, lead 27·5 = 100. The lead is sometimes replaced in part by silver and copper, and the sulphur by selenium.

**Var.**—1. *Ordinary.*—Analyses 1, 2, H. Sjögren, l. c.

2. *Argentiferous—Alaskaite.* Analyses 3, 4, Koenig, l. c.; in 3, 2·3 p. c. chalcopyrite and 15 p. c. barite have been deducted; in 4, 4·7 p. c. chalcopyrite and 2·8 p. c. barite. G. = 6·878. 5, Id., ib., **22**, 211, 1885.

3 *Seleniferous.*—A variety from Falun, Sweden, more or less impure, see Atterberg, G. För. Förh., **2**, 76, 1874, who gives an analysis of a mineral (with Se = 1·15 p. c.) regarded as a mixture of native bismuth and a sulphobismuthite of lead; also Nordström, ib. **4**, 268, 1879, with Se = 4·79–5·11 p. c. Anal. 6, Genth, Am. Phil. Soc. **23**, 34, 1885. H. = 2. Color dark lead-gray. Cleavage in one direction, eminent. 7, Weibull, G. För. Förh., **7**, 657, 1885.

| | | | S | Se | Bi | Pb | Ag | Cu | Zn | |
|---|---|---|---|---|---|---|---|---|---|---|
| 1. Nordmark | G. = 6·88 | | 17·35 | — | 54·69 | 27·65 | — | — | — | = 99·69 |
| 2. “ | | | 16·78 | — | 54·13 | 27·18 | — | — | — | = 98·09 |
| 3. *Alaskaite* | G. = 6·878 | $\frac{2}{2}$ | 17·63 | — | 56·97 | 11·79 | 8·74 | 3·46 | 0·79 | Sb 0·62 = 100 |

| 6. Falun | G. = 7·145 | $\frac{5}{5}$ | 9·75 | 12·43 | 49·88 | 27·88 | 0·33 | — | — | = 100·27 [= 99·28 |
| 7. “ | G. = 6·97 | | 9·82 | 13·61 | 49·73 | 24·62 | — | 0·77 | — | Fe 0·61 = 99·16 |

**Pyr.**—B.B. fuses easily on charcoal, giving bismuth and lead coatings. The argentiferous variety yields silver, and the seleniferous the odor of selenium. Dissolves with difficulty in hydrochloric acid, readily in strong nitric acid.

**Obs.**—Occurs with bismutite at the Ko mine, Nordmark in Wermland, Sweden, where it sometimes carries gold. Also intimately mixed with quartz, barite, chalcopyrite, and tetrahedrite, at the Alaska mine, Poughkeepsie Gulch, Colorado (*alaskaite*). The seleniferous variety is from Falun, Sweden; it occurs with native bismuth.

**119. BERTHIERITE.** Haidingerite *Berthier*, Ann. Ch. Phys., **35**, 351, 1827; Pogg., **11**, 478, 1827. Berthierit *Haid.*, Ed. J. Sc., **7**, 353, 1827. Eisenantimonglanz *Germ.*

In elongated prisms; also fibrous massive, plumose; granular.

Cleavage: longitudinal, rather indistinct. H. = 2–3. G. = 4–4·3. Luster metallic. Color dark steel-gray, inclining to pinchbeck-brown; surface often covered with iridescent spots. Opaque.

**Comp.**—Probably $FeSb_2S_4$ or $FeS.Sb_2S_3$ = Sulphur 30·2, antimony 56·6, iron 13·2 = 100.

Analyses show a somewhat varying composition, doubtless due to the impurity of the material examined, cf. Fischer, Zs. Kr., **4**, 362, 1880.

**Anal.**—1, Berthier, l. c. 2, Rg., Pogg., **40**, 153, 1837. 3, Pettko, Haid. Ber., **1**, 62, 1847. 4, Hauer, Jb. G. Reichs., **4**, 635, 1853. 5, Sackur, Rg., Min. Ch., 988, 1860. 6, Rg., Zs. G. Ges., **18**, 244, 1866.

| | | S | Sb | Fe | Zn | | |
|---|---|---|---|---|---|---|---|
| 1. Chazelles | | 30·3 | 52·0 | 16·0 | 0·3 | | = 98·6 |
| 2. Bräunsdorf | | 31·33 | 54·70 | 11·43 | 0·74 | Mn 2·54 | = 100·74 |
| 3. Arany Idka | G. = 4·043 | 29·27 | 57·88 | 12·85 | — | | = 100 |
| 4. Bräunsdorf | | 30·53 | 59·30 | 10·16 | — | | = 99·99 |
| 5. " | | 28·77 | 56·91 | 10·55 | — | Mn 3·73 | = 99·96 |
| 6. S. Antonio, Cal. | G. = 4·062 | 29·12 | 56·61 | 10·09 | — | Mn 3·56 | = 99·38 |

Other analyses by Berthier (Ann. Mines, **3**, 49, 1833) gave:

Anglar $Sb_2S_3$ 80·6 FeS 19·4 deducting 7 p.c. gangue.
Martouret 84·3 15·7 " 60 " "

These correspond approximately to $FeS.Sb_2S_3$ and $3FeS.4Sb_2S_3$. while anal. (1) above gives $3FeS.2Sb_2S_3$; little dependence can be placed upon them. N. Nordenskiöld in his Atom.-Ch. Min. System, 1848, introduces for the three varieties analyzed by Berthier the following names: *Anglarite* for $FeS.Sb_2S_3$, *Chazellite* for $3FeS.2Sb_2S_3$, *Martourite* for $3FeS.4Sb_2S_3$.

**Pyr., etc.**—In the closed tube fuses, and gives a faint sublimate of sulphur; with a strong heat yields a black sublimate of antimony oxysulphide, which on cooling becomes brownish-red. In the open tube gives off fumes of sulphur and antimony, reacting like stibnite. B.B. on charcoal gives off sulphurous and antimonial fumes, coats the coal white, and the antimony is expelled, leaving a black magnetic slag, which with the fluxes reacts for iron.

Dissolves readily in hydrochloric acid, giving off hydrogen sulphide.

**Obs.**—At Chazelles and Martouret in Auvergne, associated with quartz, calcite, and pyrite; in the Vosges, Commune of Lalaye; at Anglar, Depart. La Creuse; also at Bräunsdorf near Freiberg in Saxony, and at Padstow in Cornwall; at Arany Idka in Hungary; at Real San Antonio, Lower California, massive; N. Brunswick, probably from the antimony mine in Prince William parish. 25 miles from Fredericton, York Co.

Named after the French chemist, Pierre Berthier (1782–1861).

---

**120. MATILDITE.** Silberwismuthglanz *Rammelsberg*, Zs. G. Ges., **29**, 80, 1877. Matildite *A. D'Achiardi*, I Metalli, **1**, 136, 1883. Morocochite *Heddle*, Enc. Brit., **16**, 394, 1883. Argento-bismutite *Genth*, Am. Phil. Soc. 23, 35, 1885.

In slender striated prismatic crystals; also massive, compact.

Soft. G. = 6·92. Luster metallic. Color gray. Streak light gray. Opaque.

**Comp.**—$AgBiS_2$ or $Ag_2S.Bi_2S_3$ = Sulphur 16·9, bismuth 54·7, silver 28·4 = 100. Sometimes with lead replacing part of the silver and hence tending toward galenobismutite (p. 114).

**Anal.**—1, Rg., l. c., after deducting some galena. 2, Genth, l. c.

| | | S | Bi | Ag | Pb | |
|---|---|---|---|---|---|---|
| 1. Peru | G. = 6·92 | ⅜ 17·24 | 54·50 | 28·26 | — | = 100 |
| 2. Colorado | | [16·66] | 52·89 | 26·39 | 4·06 | = 100 |

**Pyr.**—B.B. fuses readily on charcoal, giving a coating of bismuth oxide and on long blowing a globule of silver. Soluble in nitric acid with separation of sulphur.

**Obs.**—Associated with tetrahedrite, galena, sphalerite, and pyrite at the Matilda mine, near Morococha, Peru. Also from Lake City, Colorado.

**Artif.**—Obtained by Schneider, but not in distinct crystals, J. pr. Ch., **41**, 414, 1890.

PLENARGYRITE *Sandberger*, Erzgänge, **1**, 96, 1882.

In indistinct crystals and crystalline groups, apparently like miargyrite in form. Fracture conchoidal. Brittle. H. = 2·5. G. = 7·22 (calc.). Luster metallic. Color iron-black. Streak black. Opaque.

COMP.—Probably like matildite, $AgBiS_2$ or $Ag_2S.Bi_2S_3$. Anal.—Zeitszchel, after deducting 15·83 p.c. pyrite, 1·46 quartz:

S 18·31 Bi 55·20 Ag 26·49 = 100

Occurs intimately associated with pyrite, chalcopyrite, and quartz at Schapbach, Baden. The name is stated to have been given in allusion to the fact that it contains less silver than miargyrite.

**121. MIARGYRITE.** Hemiprismatische Rubin-Blende (fr. Bräunsdorf) *Mohs*, Grundr., 606, 1824. Miargyrit *H. Rose*, Pogg., 15, 469, 1829. Hypargyrite, Hypargyron-Blende (fr. Clausthal) *Breith.*, Char., 286, 333, 1832. Kenngottite (fr. Felsöbánya) *Haid.*, Ber. Ak. Wien. 22, 236, 1856.

Monoclinic. Axes à : b̄ : ċ = 2·99449 : 1 : 2·90951; β = 81° 22′ 35″ = 001 ∧ 100 Lewis[1].

| 3. | Felsöbánya | G. = 5·298 | $\frac{2}{2}$ | 21·80 | 40·68 | 32·77 | 4·01 | 0·51 | 0·19 | = 99·96 |
| 4. | *Kenngottite* | G. = 5·337 | | 20·66 | 39·46 | 35·28 | 1·76 | 0·50 | 0·25 | = 97·91 |
| 5. | *Hypargyrite* | | $\frac{2}{2}$ | 21·35 | 41·07 | 37·40 | — | — | — | As 0·79 = 100·61 |
| 6. | Přibram | G. = 5·077 | | 21·68 | 41·15 | 36·71 | — | — | *tr.* | = 99·54 |

**Pyr., etc.**—In the closed tube decrepitates, fuses easily, and gives a sublimate of antimony oxysulphide; in the open tube sulphurous and antimonial fumes, the latter as a white sublimate. BB. on charcoal fuses quietly with emission of sulphur and antimony fumes to a gray bead, which after continued treatment in O.F. leaves a bright globule of silver. If the silver globule is treated with phosphorus salt in O.F., the green glass thus obtained often shows traces of copper when fused with tin in R.F.

Decomposed by nitric acid, with separation of sulphur and antimony trioxide.

**Obs.**—At Bräunsdorf, near Freiberg in Saxony, associated with tetrahedrite, pyrargyrite, etc.; Felsöbánya (*kenngottite*) with pyrite, galena, sphalerite, barite; Přibram in Bohemia; Clausthal (*hypargyrite*); Guadalajara in Spain; at Parenos, and the mine Sta. M. de Catorce, San Luis Potosi, Mexico; also at Molinares, with rhodochrosite; at Tres Puntas, Chili.

Named from μείων, *less*, ἄργυρος, *silver*, because it contains less silver than some kindred ores.

**Artif.**—Formed artificially by Doelter, Zs. Kr., **11**, 39, 1885.

**Ref.**—[1] Result deduced (recalc., E.S.D.) from many measurements, Zs. Kr., **8**, 545, 1884. For earlier observations see Naumann, Pogg., **17**, 142, 1829; Miller, Min., p. 214; Weisb., Pogg., **125**, 441, 1865, and Zs. Kr., **2**, 55, 1877; Friedländer, Min.-Samml. Strassburg, p. 58, 1878; Rath, Zs. Kr., **8**, 25, 1883; Lewis, ib., 545, 1884. With Weisb. and Rath $a = 101$, $o = 100$, $g = 110$, etc. In general for $h\,k\,l$ (Lewis) and $p\,q\,r$ (Weisb.), $h = -p$, $k = \frac{q}{3}$, $l = p + r$.

[2] See Rath and Lewis for authorities, etc., but note Lewis's explanation of Miller's error in identifying the forms, and the consequent rejection of several planes included by Rath.

*ar* = 50° 13½′
*ax* = 46° 24′
*ay* = 45° 47½′
*a′ω* = 85° 42½′

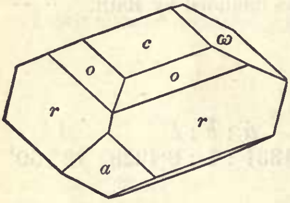
Crystals thick tabular ‖ *c*, or short prismatic ‖ *r*; often grouped in druses and geodes. Faces *c* smooth, pyramids striated ‖ edge *c*/*o*. Also massive; granular to compact.

Cleavage: *r* tolerably perfect. Fracture conchoidal to uneven. Brittle. H. = 2·5. G. = 5·4. Luster metallic. Color and streak blackish lead-gray. Opaque.

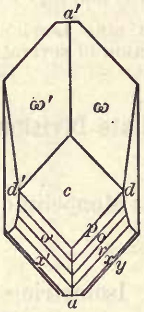
**Comp.**—Perhaps $5PbS.4Sb_2S_3$ = Sulphur 21·5, antimony 37·8, lead 40·7 = 100.

**Anal.**—1, H. Rose, Pogg., **28**, 422, 1833. 2, Kudernatsch, ib., **37**, 588, 1836. 3, Schultz, Rg., Min. Ch., 1006, 1860.

1.



2.



Figs. Wolfsberg; 1, Rose; 2, after Luedecke.

| | S | Sb | Pb | | |
|---|---|---|---|---|---|
| 1. Wolfsberg | 21·53 | 37·94 | 40·52 | | = 99·99 |
| 2. " | 21·49 | [37·53] | 40·98 | | = 100 |
| 3. " | 21·10 | 37·84 | 39·36 | Cu 1·27 | = 99·57 |

**Pyr.**—Same as for zinkenite.

**Obs.**—At Wolfsberg in geodes and druses of crystals in massive plagionite, or crystallized on quartz, discovered by Zincken; also at Wolfach, Baden; Arnsberg, Westphalia.

Named, in allusion to its unusually oblique crystallization, from *πλάγιος, oblique*.

**Ref.**—[1] Jb. Min., **2**, 112, 1883; Rose obtained earlier (l. c.) *ac* = 72° 28′, *rr′* = 59° 11′, *cr* = 41° 8′, etc. [2] Luedecke, l. c.

---

**123. BINNITE.** Dufrenoysite *Waltershausen*, Pogg., **94**, 119, 1855; *C. Heusser*, Pogg., **94**, 334, **97**, 115. Binnite *Dx.*, Ann. Mines, **8**, 389, 1855.

Isometric. Observed forms[1]:

*a* (100, *i*-*i*)
*d* (110, *i*)
*o* (111, 1)
*r* (332, $\frac{3}{2}$)
*ω* (441, 4)
*Ψ* (10·1·1, 10-10)
*ψ* (711, 7-7)[2]
*φ* (611, 6-6)
*μ* (411, 4-4)
*n* (211, 2-2)
*s* (321, 3-$\frac{3}{2}$)

In complex crystals; also massive.

Cleavage not distinct. Fracture conchoidal. Brittle. H. = 2·5–3. G. = 4·477. Luster metallic. Color dark steel-gray to iron-black, sometimes brownish. Streak reddish brown. Opaque.

**Comp.**—Perhaps $Cu_6As_4S_9$ or $3Cu_2S.2As_2S_3$ = Sulphur 29·8, arsenic 31·0, copper 39·2 = 100.

**Anal.**—Uhrlaub, Pogg., **94**, 120, 1855.

| S | As | Cu | Pb | Ag | Fe |
|---|---|---|---|---|---|
| 27·55 | 30·06 | 37·74 | 2·75 | 1·23 | 0·82 = 100·15 |

A second analysis (of the same mineral?) by Stockar-Escher (5th Ed., p. 90) is near enargite; as also another by McIvor, viz.: S 32·46, As 18·79, Cu 46·05, Ag 2·43 = 99·73. Ch. News, **30**, 103, 1874. The true character and place of binnite is hence in doubt.

**Pyr.**—In the closed tube gives a sublimate of arsenic trisulphide; in the open tube a crystalline sublimate of arsenic trioxide, with sulphurous fumes. B.B. on charcoal gives an arsenical odor and a faint white coating, fuses with intumescence to a dull iron-black globule which yields metallic copper with soda.

**Obs.**—In the Binnenthal in cavities in crystalline dolomite with realgar, orpiment, sphalerite, pyrite, sartorite, and dufrenoysite.

**Ref.**—[1] Hbg., Min. Not., 1875, p. 6, gives authorities and new forms, and discusses the supposed hemihedral character of the species with a negative conclusion. [2] Lewis, Zs. Kr., **2**, 192, 1878.

### 124. KLAPROTHOLITE.

Kupferwismutherz, Wismuthkupfererz, pt. Klaprothit, *Petersen* and *Sandberger*, Jb. Min., 415, 1868. Klaprotholite, *G. J. Brush*, Dana Min., App. I., 8, 1872.

Orthorhombic. Occurs in longitudinally furrowed prismatic crystals, with *a*, *m*, and *u* (*h0l*, *m-ī*)?; *mm'''* = 73° approx. Twins: tw. pl. *m*.

Cleavage: *a* distinct. Fracture uneven. Brittle. H. = 2·5. G.= 4·6 Petersen. Luster metallic. Color steel-gray, tarnishing to brass-yellow or iridescent. Streak black.

**Comp.**—$Cu_6Bi_4S_9$ or $3Cu_2S.2Bi_2S_3$ = Sulphur 19·3, bismuth 55·4, copper 25·3 = 100.

**Anal.**—1, Schneider, Pogg., **127**, 309, 1866. 2, Petersen, l. c.

| | S | Bi | Cu | Fe |
|---|---|---|---|---|
| 1. Wittichen | $\frac{2}{2}$ 18·69 | 51·40 | 28·82 | 0·91 = 99·82 |
| 2. " | $\frac{3}{3}$ 18·66 | 53·87 | 23·96 | 1·70 = 98·19 |

**Pyr.**—Same as for emplectite.

**Obs.**—Occurs with other bismuth minerals, and especially with cobalt tetrahedrite and chalcopyrite at the Daniel mine near Wittichen, Baden; at Freudenstadt; Eberhard mine near Alpirsbach, and other localities in the Black Forest. The mineral examined by Schneider was referred to wittichenite by Hilger.

The name klaprothite (after the German mineralogist, M. H. Klaproth, 1743–1817) was given to lazulite by Beudant in 1824, hence the change of Petersen's name to klaprotholite.

### 125. SCHIRMERITE.

*Genth*, Am. Phil. Soc., **14**, 230, 1874.

Massive, finely granular, disseminated.

Cleavage none. Fracture uneven; soft; brittle. G. = 6·737. Luster metallic. Color lead-gray, inclining to iron-black.

**Comp.**—$3(Ag_2,Pb)S.2Bi_2S_3$ = Sulphur 11·8, bismuth 47·3, lead 16·4, silver 24·5 = 100, if $Ag_2 : Pb = 2 : 1$.

**Anal.**—1, 2, Genth, l. c.; in 1, 1 p. c. quartz deducted, in 2, 1·07 p. c. deducted.

| | S | Bi | Pb | Ag | Zn | Fe |
|---|---|---|---|---|---|---|
| 1. | 14·41 | 46·91 | 12·69 | 22·82 | 0·08 | 0·03 = 96·94 |
| 2. | 15·02 | [47·27] | 12·76 | 24·75 | 0·13 | 0·07 = 100·00 |

**Pyr.**—B.B. fuses easily, and gives sulphurous fumes with reactions for bismuth, lead, and silver.

**Obs.**—Occurs with several tellurium minerals at Treasury lode, Park Co., Colorado.

Named from J. F. L. Schirmer, Esq.

*Schirmerite* of Endlich (Eng. Mng. J., Aug. 29, 1874), containing tellurium, gold, silver iron, is a mixture according to Genth.

**126. WARRENITE.** Sulphantimonite from Colorado *L. G. Eakins*, Am. J. Sc., **36**, 450, 1888. Domingit *Groth*, Tab. Ueb., 30, 1889.

In aggregates of acicular crystals, forming matted, wool-like masses.

Luster metallic, dull. Color grayish black, sometimes iridescent in spots. Opaque.

**Comp.**—$Pb_3Sb_4S_9$ or $3PbS.2Sb_2S_3$ = Sulphur 20·8, antimony 34·6, lead 44·6 = 100. Iron is present in small amount.

**Anal.**—Eakins, l. c.

S 21·19 Sb 36·34 Pb 39·33 Fe 1·77 Ag, Cu, Mn *tr.*, gangue 0·52 = 99·15

**Pyr., etc.**—Fuses easily. In the closed tube a slight sublimate of sulphur; in the open tube sulphurous fumes and a white sublimate of antimony trioxide. On charcoal sublimates of the oxides of lead and antimony, and in R. F. a lead button. Soluble in hot hydrochloric acid with evolution of hydrogen sulphide.

**Obs.**—From the Domingo mine, Gunnison Co., Colorado, where it occurs in cavities in a decomposed siliceous rock mixed with some calcite, locally called "mineral wool."

Named by Eakins after Mr. E. R. Warren of Crested Butte, Col.

---

**127. DUFRENOYSITE.** Dufrenoysite *Damour*, Ann. Ch. Phys., **14**, 379, 1845. Gotthardit *Rg.*, Berz. Ch. Min., 229, 256, 1847. Arsenomelan and Scleroclase pt. *Waltersh.* Pogg., **94**, 115, 1855. Dufrenoysite pt. *Dx.*, Ann. Mines, 8, 389, 1856. Skleroklas *Petersen*, Offenb. Ver., **7**, 13, Jb. Min., 203, 1867. Bleiarsenit, *Groth*, Tab. Ueb., p. 18, 1874.

Orthorhombic. Axes: $\breve{a} : \bar{b} : \dot{c}$ = 0·9381 : 0 : 1·5309 Rath[1].

100 ∧ 110 = 43° $10\frac{1}{4}'$, 001 ∧ 101 = *58° 30′, 001 ∧ 011 = 56° $50\frac{5}{6}'$.

**Forms**[2]:

| 3. " | G. = 5·56 | 23·27 | 21·76 | 53·62 | 0·05 | 0·30 | — | = 99·0 |

**Pyr., etc.**—In the closed tube easily fuses and gives a sublimate of sulphur and arsenic trisulphide; in the open tube gives sulphurous fumes ($SO_2$) and a white crystalline sublimate of arsenic trioxide. On charcoal decrepitates, fuses, yields fumes of arsenic and a globule of lead, which on cupellation yields silver.

**Obs.**—From the Binnenthal in Switzerland, in cavities in crystalline dolomite, along with sartorite, jordanite, binnite, realgar, orpiment, sphalerite, pyrite.

Damour, who first studied the sulpharsenites of the Binnenthal, analyzed the massive ore and named it *dufrenoysite* (after the French mineralogist, P. A. Dufrénoy, 1792–1857). He inferred that the crystallization was isometric from some associated crystals, and so published it. This led von Waltershausen and Heusser to call the isometric mineral dufrenoysite, and the latter to name the orthorhombic *binnite.* Von Waltershausen, after studying the prismatic mineral, made out the species *arsenomelan* and *scleroclase*, yet partly on hypothetical grounds. Later it was found that three orthorhombic minerals existed at the locality, as announced by vom Rath, who identified one, by specific gravity and composition, with Damour's *dufrenoysite;* another he made *scleroclase* of von Waltershausen (sartorite, p. 112); and the other he named *jordanite* (p. 141).

**Ref.**—[1] Pogg., **122**, 373, 1864. See earlier Dx., Ann. Mines, 8, 389, 1855; Heusser, Pogg., **97**, 120, 1856; Berendes, Inaug. Diss., Bonn, 1864. [2] Cf. Berendes, l. c.

**128. COSALITE.** *Genth,* Am. J. Sc., **45**, 319, 1868. Ett nytt vismutsvafladt svafvelbly *Lundström,* G. För. Förh., **2**, 178, 1874. Bleibismutit *Groth,* Tab. Ueb., 18, 1874. **Bjelkite** *H. Sjögren,* G. För. Förh., **4** 107, 1878.

Orthorhombic. Axes: $\breve{a} : \bar{b} : \acute{c} = 0·91874 : 1 : 1·4601$ Flink.[1]

$100 \wedge 110 = 42° \ 34' \ 30''$, $001 \wedge 101 = 57° \ 49' \ 14''$, $001 \wedge 011 = {}^{*}55° \ 35' \ 36''$.

**Pyr.**—B.B. fuses easily, giving the usual reactions for sulphur, bismuth, and lead; some varieties yield a small globule of silver.

**Obs.**—Found associated with quartz and cobaltite in a silver mine at Cosala, Province of Sinaloa, Mexico. An argentiferous variety (anal. 9) occurs at Candameña, Chihuahua. In calcite at the Bjelke mine, at Nordmark, Wermland, Sweden (*bjelkite*); also at Gladhammar. At Rezbanya, Hungary, with sphalerite, pyrite, and chalcopyrite; an impure form of this mineral was called *rezbanyite* (retzbanyite) by Hermann, J. pr. Ch., **75**, 450, 1859; cf. Frenzel, l. c.

In the U. S., from the Comstock mine (anal. 10), near Parrott City, La Plata county, Col., in a quartz vein with pyrite, sphalerite, a telluride probably sylvanite and native gold. Also from the Gladiator and Alaska mines, Colorado, and at the Yankee Girl mine, Red Mt., San Juan county.

**Ref.**—[1] Ak. H. Stockh., Bihang, **12** (2), No. 2, 6, 1886.

**129. SCHAPBACHITE.** Wismutisches Silber *Selb*, Crell's Ann., **1**, 10, 1793. Wismuthbleierz. Schapbachit *Kenngott*, Min., 118, 1853. *Sandberger* Erzgänge, **1**, 90, 1882.

Orthorhombic? In minute acicular crystals, with *b, c, m*; $mm''' = 75°$. Also fine granular, massive.

Cleavage: basal, distinct. Fracture uneven. H. = 3·5. G. = 6·43. Luster metallic. Color lead-gray. Streak black. Opaque.

**Comp.**—$PbAg_2Bi_2S_6$ or $PbS.Ag_2S.Bi_2S_3$ = Sulphur 16·1, bismuth 41·6, lead 20·7, silver 21·6 = 100.

**Anal.**—Hilger, l. c., after deducting 1·86 p. c. pyrite.

S 16·08 Bi 42·02 Pb 20·82 Ag 21·08 = 100

This species may be regarded as an argentiferous variety of cosalite.

**Obs.**—From Schapbach, Baden, intimately associated with galena, pyrite and chalcopyrite, quartz and native bismuth or bismuthinite. Earlier regarded as merely a mixture of bismuthinite, argentite and galena (cf. Sandberger, Jb. Min., 22, 1864).

**Pyr.**—Same as for zinkenite.

**Obs.**—Occurs principally in Cornwall, associated with quartz and minute crystals of bournonite; occasionally also in Siberia, Hungary, at Valentia d'Alcantara in Spain, and Brazil; at the antimony mines in Sevier Co., Arkansas; at the Montezuma mine, Nevada. Named after Prof. Robert Jameson of Edinburgh (1774–1854).

The *feather ore* (Federerz *Germ.*) occurs at Wolfsberg in the Eastern Harz; also at Andreasberg and Clausthal; at Freiberg and Schemnitz; in the Anhalt at Pfaffenberg and Meiseberg; in Tuscany, near Bottino; at Chonta in Peru. It was regarded as a species by nearly all the mineralogists of last century, but included capillary stibnite; made a variety of stibnite by v. Born, Karsten, Haüy, Mohs, Leonhard, and other authors, until 1829; and a distinct species again by most authors after the analysis by Rose in 1829; but referred to jamesonite by v. Kobell in 1830, and Rammelsberg in 1860.

*Zundererz*, or Bergzunderz [ = Tinder Ore] of G. Lehmann (Mem. Ak. Berlin, 20, 1758), which is soft like tinder and dark dirty red in color, has been referred to kermesite, but proves to be an impure jamesonite or feather ore sometimes mixed with red silver and arsenopyrite; also with free sulphur. From Andreasberg and Clausthal in the Harz.

**Alt.**—The lead antimonate, bindheimite, is a common alteration product.

**Artif.**—Obtained by Doelter in forms resembling the natural mineral, Zs. Kr., **11**, 40, 1885.

---

**131. KOBELLITE.** Kobellit *Sätterberg*, Ak. H. Stockh., 188, 1839; Berz. Jahresb., **20**, 215.

Massive, sometimes fibrous and radiated, resembling stibnite; also fine granular.

H. = 2·5–3. G. = 6·29–6·32 Sätterberg; 6·334 Keller. Color blackish lead-gray to steel-gray. Streak black.

**Comp.**—$Pb_2(Bi,Sb)_2S_5$ or $2PbS.(Bi,Sb)_2S_3$ = (if Bi : Sb = 2 : 1) Sulphur 17·2, bismuth 29·8, antimony 8·6, lead 44·4 = 100. Silver is also present.

**Anal.**—1, Sätterberg, recalculated by Rammelsberg, Min. Ch., 100, 1875. 2, H. F. Keller, Zs. Kr., **17**, 67, 1889, deducting impurities.

| | S | Bi | Sb | Pb | Ag | Cu | Fe |
|---|---|---|---|---|---|---|---|
| 1. Sweden | [18·61] | 28·37 | 9·38 | 40·74 | — | 0·88 | 2·02 = 100 |
| 2. Colorado $\frac{4}{4}$ | 17·76 | 30·61 | 8·13 | 38·95 | 3·58 | 0·97 | — = 100 |

**Pyr., etc.**—B.B. decrepitates, and fuses easily; in the open tube sulphurous fumes and a sublimate of antimony trioxide; on charcoal, a yellow coating ($Bi_2O_3$) near the assay and beyond white ($Sb_2O_3$); with potassium iodide and sulphur a bright red coating (bismuth iodide). Soluble in concentrated hydrochloric acid with evolution of hydrogen sulphide.

**Obs.**—From the cobalt mine of Hvena in Sweden, associated with actinolite, chalcopyrite, and small reddish white crystals of a cobaltiferous arsenopyrite (Kobaltarsenikkies). Also from the Silver Bell mine at Ouray, Colorado, associated with chalcopyrite and barite.

Named after the Bavarian mineralogist and poet, Franz von Kobell (1803–1882).

Rammelsberg rejected Sätterberg's analysis, and on the basis of analyses by himself and Genth deduced the composition $3PbS.(Bi,Sb)_2S_3$. Keller, however, has proved the existence of the compound $2PbS.(Bi,Sb)_2S_3$, to which Sätterberg's analysis conforms, and to the other has given the name of *lillianite* (p. 130); cf. also Groth, Tab. Ueb., pp. 30, 31, 1889. If this conclusion is correct, both these compounds must occur at the Swedish locality.

**132. BRONGNIARDITE.** *Damour*, Ann. Mines, **16**, 227, 1849. Bleisilberantimonit *Groth*, Tab. Ueb., 18, 1874.

Isometric. In octahedrons (*o*) with truncated edges (*d*). Massive without cleavage.

H. above 3. G. = 5·950. Luster metallic. Color and streak grayish black.

**Comp.**—$PbAg_2Sb_2S_5$ or $PbS.Ag_2S.Sb_2S_3$ = Sulphur 19·5, antimony 29·2, silver 26·2, lead 25·1 = 100.

**Anal.**—Damour, l. c.:

| | S | Sb | Ag | Pb | Cu | Fe | Zn |
|---|---|---|---|---|---|---|---|
| $\frac{3}{3}$ | 19·24 | 29·77 | 24·77 | 24·91 | 0·62 | 0·26 | 0·36 = 99·93 |

**Pyr., etc.**—In the closed tube a feeble orange sublimate with a white one above; in the open tube fuses, affords an odor of sulphur and a white sublimate of antimony trioxide. B B. on charcoal decrepitates, fuses easily, giving off an odor of sulphur and white vapors; after roasting, yields a globule of silver, with a yellow coating of lead oxide. Rapidly attacked by concentrated nitric acid.

**Obs.**—From Mexico. Named for the French mineralogist, Alexandre Brongniart (1770–1847).

---

**133. SEMSEYITE.** *Krenner* [Mag. Akad. Értes., **15**, 111, 1881], Ungar. Revue, 367, 1881; Zs. Kr. 8, 532, 1883.

Monoclinic. Axes $\grave{a} : \overset{|}{b} : \grave{c}$ = 1·14424 : 1 : 1·10515; $\beta$ = 71° 4′ = 100 ∧ 001 Krenner[1].

100 ∧ 110 = 47° 15$\frac{5}{6}$′, 001 ∧ 101 = 34° 49$\frac{1}{3}$′, 001 ∧ 011 = 46° 16$\frac{1}{4}$′.

**Forms:** *a* (100, *i-ī*), *c* (001, *O*), *s* (113, − $\frac{1}{3}$), *p* (111, − 1), *q* (221, − 2), *t* ($\bar{1}$13, $\frac{1}{3}$).

Angles: *cs* = *22° 44′, *cp* = 46° 35′, *cq* = *59° 38′, *ct* = 27° 20′, *ss′* = 33° 50′, *pp′* = 66° 19′, *qq′* = 81° 2′, *qq″* = *98° 58′, *tt′* = 40° 27′.

In small tabular crystals, often elongated ‖ $\bar{b}$.

Cleavage: pyramidal, *p*. G. = 5·952 Sipöcz. Luster metallic. Color gray. Opaque.

**Comp.**—Near jamesonite, perhaps $Pb_7Sb_6S_{16}$ or $7PbS.3Sb_2S_3$ = Sulphur 19·1, antimony 26·9, lead 54·0 = 100.

**Anal.**—Sipöcz, Zs. Kr., **11**, 216, 1885.

S 19·42 Sb 26·90 Pb 53·16 Fe 0·10 = 99·58

**Obs.**—Occurs with galena, also diaphorite, sphalerite and pyrite at Felsöbánya, Hungary. Named for Andor von Semsey.

**Ref.**—[1] Zs. Kr., **8**, 532, 1883.

---

**134. DIAPHORITE.** Freieslebenite pt. Diaphorit *Zepharovich*, Ber. Ak. Wien, **63** (1), 130, 1871.

Orthorhombic. Axes $\breve{a} : \bar{b} : \dot{c}$ = 0·49194 : 1 : 0·73447 Zepharovich.

100 ∧ 110 = 26° 11$\frac{2}{3}$′, 001 ∧ 101 = 56° 11$\frac{1}{6}$′, 001 ∧ 011 = 36° 17$\frac{3}{4}$′.

| 6. Colorado | | 18·98[a] | 25·99 | 55·52 | *tr.* | *tr.* | = 100·49 |

[a] By calculation.

Pisani refers here the massive dark *Weissgültigerz* analyzed by Klaproth, who obtained (l.c.) S 22·00, Sb 21·50, Pb 41·00, Ag 9·25, Fe 1·75, $Al_2O_3$ 1·00, $SiO_2$ 0·75 = 97·25, considering part of the silver as here replaced by lead.

**Pyr.**—In the open tube gives sulphurous and antimonial fumes, the latter condensing as a white sublimate. B.B. on charcoal fuses easily, giving a coating, on the outer edge white, from antimony trioxide, and near the assay yellow, from lead oxide; continued blowing leaves a globule of silver.

**Obs.**—With argentite, siderite, and galena, in the Himmelsfürst mine, at Freiberg in Saxony; at Kapnik in Hungary; at Ratieborzitz, the ore of which locality contains bismuth, according to Zincken; at Felsöbánya; at Hiendelencina in Spain, with argentite, red silver, siderite, galena, etc. In groups of acicular crystals of a bright steely grayish black color from the Augusta Mt., Gunnison Co., Colorado (anal. 6). Formerly regarded as occurring at Přibram, but this mineral is referred to diaphorite (Zeph.).

Named after J. K. Freiesleben (1774–1846).

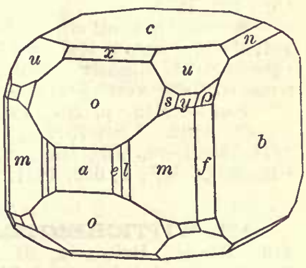

Fig. 1, Harz, Lévy. 2, 5, Nagyág, Zirkel. 3, Kapnik, Hbg.-Schrauf. 4, Harz, Zirkel. 6, Liskeard, Miers.

Twins: tw. pl. *m*, often repeated forming cruciform and wheel-shaped crystals, with also enclosed twin lamellæ. Crystals usually short prismatic to tabular; often aggregated in parallel position; prismatic faces often vertically striated, also macrodomes horizontally. Also massive; granular, compact.

Cleavage: *b* imperfect; *a*, *c* less distinct. Fracture subconchoidal to uneven. Rather brittle. H. = 2·5–3. G. = 5·7–5·9. Luster metallic, brilliant. Color and streak steel-gray, inclining to blackish lead-gray or iron-black. Opaque.

**Comp.**—$(Pb,Cu_2)_3Sb_2S_6$ or $3(Pb,Cu_2)S.Sb_2S_3 = PbCuSbS_3$ (if $Pb : Cu_2 = 2 : 1$) Sulphur 19·8, antimony 24·7, lead 42·5, copper 13·0 = 100.

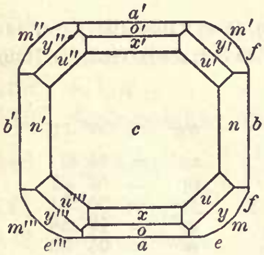
7.



**Pyr., etc.**—In the closed tube decrepitates, and gives a dark red sublimate. In the open tube gives sulphur dioxide, and a white sublimate of antimony trioxide. B.B. on charcoal fuses easily, and at first coats the coal white; continued blowing gives a yellow coating of lead oxide; the residue, treated with soda in R.F., gives a globule of copper.

Decomposed by nitric acid, affording a blue solution, and leaving a residue of sulphur, and a white powder containing antimony and lead.

**Obs.**—Occurs in the mines of Neudorf in the Harz (which include the Meiseberg localities), where the crystals occasionally exceed an inch in diameter; also at Wolfsberg, Clausthal, and Andreasberg in the Harz; at Přibram in Bohemia; with quartz, tetrahedrite, and phosphorescent sphalerite, at Kapnik in Hungary, in flattened crystals; at Servoz in Piedmont, associated with pearl spar and quartz. Other localities are the parish of Bräunsdorf and Gersdorf in Saxony, Olsa in Carinthia, etc.; Endellion at Wheal Boys in Cornwall, where it was first found, and hence called *endellione*, by Count Bournon, after whom it was subsequently named; in Mexico; at Huasco-Alto in Chili; Mina Beatriz, Sierra Gorda, Atacama; at Machacamarca in Bolivia; in Peru.

In the U. S., at the Boggs mine, Yavapai Co , Arizona (Blake), with pyrite, chalcopyrite, etc.: also from Montgomery Co., Arkansas, with galena, tetrahedrite, etc. (F. W. Gibb). Also reported from the Bear and Anvil Mts., San Juan Co., Colorado. In Canada, in the township of Marmora, Hastings Co., and Darling, Lanark Co., Ontario.

**Alt.**—Occurs altered to cerussite, malachite, azurite, and also (as Rammelsberg has shown) to the mineral called *wölchite* (Antimonkupferglanz *Germ.*), which occurs in similar crystals, with the same hardness and same sp. gr. (5·88–5·94 Rg.). It was originally from Wölch in Carinthia, but occurs also at Olsa, with true bournonite. Rammelsberg found, as the mean of 4 analyses (Min. Ch., 80, 1860), S 16·81, Sb 24·41, Pb 15·59, Cu 42·83, Fe 0·36 = 100, excluding the admixed carbonate, sulphate, and antimonial salts of lead and copper, and some water. See Min. Ch., 102, 1875.

**Artif.**—On synthetic experiments, Doelter, Zs. Kr., **11**, 38, 1885. Also later (Anz. Ak. Wien, 101, 1890), where it is shown that bournonite when digested in water as a fine powder in a sealed tube at 80° is slightly soluble; in connection with these experiments crystals of the common twinned form were obtained.

**Ref.**—[1] Min. p. 201, 1852; cf. Rose, Pogg., **76**, 291, 1849, and Zirkel, Ber. Ak. Wien, **45** (1), 431, 1862. [2] See Zirkel, l. c.; Hbg., Min. **137. WITTICHENITE.** Kupferwismutherz *Selb.*, Denks. d'Aerzte u. Nat. Schwab., **1**, 419; *Klapr.*, Beitr., **4**, 91, 1807. Bismuth sulphuré cuprifère *Fr.* Cupreous Bismuth; Cupriferous Sulphuret of Bismuth. Wismuth-Kupfererz *Leonh.*, 1826. Wittichit *Kbl.*, Taf., 13, 1853. Wittichenit *Kenng.*, Uebers., 1853, 118, 1855.

Orthorhombic. In crystals resembling bournonite with *a, b, c, m, o, n*, Breith. Massive and disseminated; also coarse columnar, or an aggregate of imperfect prisms.

Fracture conchoidal. H. = 3·5. G. = 5, Hausm.; 4·3, Gallenbach, Hilger. Color steel-gray, tin-white, tarnishing pale lead-gray. Streak black.

**Comp.**—$Cu_3BiS_3$ or $3Cu_2S.Bi_2S_3$ = Sulphur 19·5, bismuth 42·1, copper 38·4 = 100.

**Anal.**—1, Petersen, Pogg., **136**, 500, 1869. 2, G. Lindström, G. För. Förh., **9**, 523, 1887. Also 5th Ed., pp. 98, 99.

| | | S | Bi | Cu | Pb | |
|---|---|---|---|---|---|---|
| 1. Gallenbach | G. = 4·45 | 20·30 | 41·13 | 36·76 | — | As 0·79, Sb 0·41, Ag 0·15, Zn 0·13, Fe 0·35 = 100·02 |
| 2. Gladhammar | G. = 6·70 | 17·70 | 42·94 | 20·86 | 18·04 | Zn 0·06, Fe 0·68, insol. 0·16 = 100·44 |

It is a question whether anal. 2 belongs here; cf. lillianite.

**Pyr.**—In the open tube gives sulphurous fumes and a white sublimate of bismuth sulphate. B.B. on charcoal fuses easily, at first throws out sparks, and coats the coal with bismuth trioxide, the residue with soda in R.F. gives a globule of metallic copper. Soluble in hydrochloric acid, with evolution of hydrogen sulphide; decomposed by nitric acid, with separation of sulphur.

**Obs.**—From cobalt mines with barite, near Wittichen, Baden; also at Zell, near Wolfach; at Christophsau near Freudenstadt. Chiefly at the Neuglück mine, Böckelsbach, also Anton mine in Heubach, David mine in Silberberg, and King David (anal. 1.) in Gallenbach. A related mineral (anal. 2) occurs at Gladhammar, Sweden.

**Alt.**—Undergoes easy alteration, becoming yellowish brown, then red and blue externally, forming apparently covellite; also changing to a greenish earthy mineral, which is a mixture of malachite, bismuth oxide, and hydrated iron sesquioxide; also to an earthy yellow bismutite and bismuth-ochre. Sandberger, Jb. Min., 274, 1865.

**Artif.**—Obtained by Schneider, Pogg., **127**, 302, 1866.

**138. AIKINITE.** Nadelerz *Mohs,* Null's Kab., 3, 726, 1804. Bismuth sulfuré plombo-cuprifère *H.*, Tabl., 105, 1809. Needle Ore; Acicular Bismuth; Cupreous Bismuth. Aikinite *Chapman,* Min., 127, 1843. Patrinite *Haid.*, Handb., 568, 1845. Belonit *Glock.*, Syn., 27, 1847. Aciculite *Nicol,* Min., 487, 1849.

Orthorhombic. Axes: $\breve{a} : \bar{b}$ = 0·9719 : 1 Miers.

**Forms:** *b* (010, *i*-$\breve{i}$), *e* (210, *i*-$\bar{2}$), *m* (110, *I*), *f* (120, *i*-$\breve{2}$), *i* (130, *i*-$\breve{3}$).

Angles: *ee'''* = 51° 50′, *mm'''* = *88° 22′, *ff'* = 54° 27′, *ii'* = 37° 52′; *be* = 64° 5′, *bf* = 27° 13½′, *bi* = 18° 56′, measured 63° 26′, 26° 34′, 19° 4′.

Crystals embedded, acicular, longitudinally striated. Also massive.

Fracture uneven. H. = 2–2·5. G. = 6·1–6·8; 6·757 Frick. Luster metallic. Color blackish lead-gray, with a pale copper-red tarnish. Opaque.

**Comp.**—$3(Pb,Cu_2)S.Bi_2S_3$ or (if Pb : $Cu_2$ = 2 : 1), $PbCuBiS_3$ = Sulphur 16·8, bismuth 36·2, lead 36·0, copper 11·0 = 100.

**Anal.**—1, 2, Frick, Pogg., **31**, 529, 1834. 3, Chapman, Phil. Mag., **31**, 541, 1847. 4, Hermann, J. pr. Ch., **75**, 452, 1858.

| | | S | Bi | Pb | Cu | Ni |
|---|---|---|---|---|---|---|
| 1. Berezov | G. = 6·757 | 16·05 | 34·62 | 35·69 | 11·79 | — = 98·15 |
| 2. " | | 16·61 | 36·45 | 36·05 | 10·59 | — = 99·70 |
| 3. " | G. = 6·1 | 18·78 | 27·93 | 40·10 | 12·53 | — = 99·34 |
| 4. " | | 16·50 | 34·87 | 36·31 | 10·97 | 0·36 Au 0·09 = 99·10 |

**Pyr., etc.**—In the open tube gives sulphurous fumes, and also a white sublimate, which may be fused into clear drops that are white on cooling; the assay becomes surrounded with a black fused oxide, which on cooling is transparent and greenish yellow. B.B. on charcoal fuses and gives a white coating, yellow on the edge nearest the assay; with the fluxes, reactions for copper, and after long blowing a globule of metallic copper.

Decomposed by nitric acid, with separation of sulphur and lead sulphate.

**Obs.**—Occurs at Berezov near Ekaterinburg, Urals, with gold, malachite, and galena, in white quartz. In the United States perhaps at Gold Hill, Rowan Co., N. Carolina (possibly cosalite, Genth).

**Ref.**—[1] Berezov, Min. Mag., 8, 206, 1889; Miers gives 410 instead of 210, but the former does not agree with the measured angle. Hoernes gave a prismatic angle of 70°.

**139. BOULANGERITE.** Plomb antimonié sulfuré *Boulanger*, Ann. Mines, **7**, 575, 1835. Schwefelantimonblei Antimonbleiblende *Germ.* Sulphuret of Antimony and Lead. Boulangerit *Thaulow,* Pogg., **41**, 216, 1837; *Hausm.*, ib., **46**, 281. Embrithite, Plumbostib, *Breith.*, J. pr. Ch., **10**, 442, 1837.

In plumose masses, exhibiting on the fracture a crystalline structure; also granular and compact.

H. = 2·5–3. G. = 5·75–6·0. Luster metallic. Color bluish lead-gray; often covered with yellow spots from oxidation. Opaque.

**Comp.**—$Pb_3Sb_2S_6$ or $3PbS.Sb_2S_3$ = Sulphur 18·3, antimony 22·8, lead 58·9 = 100.

**Anal.**—1, Genth, Am. J. Sc., **45**, 320, 1868. 2, 3, Rath, Pogg., **136**, 430, 1869. 4, 5, Frenzel, J. pr. Ch., **2**, 360, 1870. Also 5th Ed., pp. 99, 795.

| 1. Echo Distr., Nevada | | 17·91 | 26·85 | 54·82 | *tr.* | Fe 0·42 = 100 |
| 2. Silbersand | G. = 5·935 | 18·62 | 22·93 | 55·82 | — | = 97·37 |
| 3. " | | 18·51 | 25·65 | 56·14 | — | = 100·30 |
| 4. *Plumbostib* | G. = 6·17 | 18·09 | 20·49 | 59·54 | — | Cu 0·88 = 99·00 |
| 5. *Embrithite* | G. = 6·32 | 18·08 | 21·47 | 59·30 | — | Cu 0·80 = 99·65 |

The last two correspond nearly to $10PbS.3Sb_2S_3$, but the material analyzed may not have been quite pure. Cf. Guitermanite.

**Pyr.**—Same as for zinkenite.

**Obs.**—Quite abundant at Molières, department of Gard, in France; also found at Nasafjeld in Lapland; at Nerchinsk; Ober-Lahr in Sayn-Altenkirchen; Silbersand near Mayen in the Eifel; Wolfsberg in the Harz; Přibram in Bohemia; near Bottino in Tuscany, both massive, acicular, and fibrous. Also in acicular crystals embedded in quartz in Echo District, Union county, Nevada.

Named after C. L. Boulanger (1810–1849).

*Embrithite* is from the locality of boulangerite at Nerchinsk. It is granular in texture, of a lead-gray color. Named from ἐμβριθής, *heavy*. *Plumbostib* is also from Nerchinsk; it is columnar to fibrous in structure. Named from *plumbum* and *stibium*.

### 140. LILLIANITE. *H. F. Keller*, Zs. Kr., **17**, 67, 1889. Kobellite *pt.*

Massive, crystalline.

Luster metallic. Color steel-gray. Streak black. Opaque.

**Comp.**—$Pb_3Bi_2S_6 = 3PbS.Bi_2S_3$ = Sulphur 15·7, bismuth 33·8, lead 50·5 = 100. Also $Pb_3BiSbS_6$ = Sulphur 16·9, bismuth 18·2, antimony 10·5, lead 54·4 = 100. Further the lead may be in part replaced by silver, in anal. 1–3, Pb : Ag = 4 : 1.

**Anal.**—1–3, H. F. & H. A. Keller, J. Am. Ch. Soc., **7**, 194, 1885. 4, Rg., Ber. Ak. Berlin, 237, 1862, after deducting 5·61 cobaltite, 3·67 chalcopyrite. 5, Gent, Rg., Min. Ch., 100, 1875.

| | | S | Bi | Sb | Pb | Ag | Cu | |
|---|---|---|---|---|---|---|---|---|
| 1. Colorado | | 15·21 | 32·62 | — | 43·94 | 5·78 | *tr.* | = 97·55 |
| 2. " | | 15·27 | 33·31 | — | 44·28 | 5·49 | 0·03 | = 98·38 |
| 3. " | | 15·19 | 33·89 | — | 44·03 | 5·72 | *tr.* | = 98·83 |
| 4. Sweden | G. = 6·145 | 16·85 | 18·68 | 10·59 | 52·09 | — | — | Fe 0·43 = 98·64 |
| 5. " | | 17·62 | 17·89 | 10·14 | 50·66 | — | 1·46 | Fe 1·70 = 99·47 |

**Obs.**—From Hvena, Sweden, with cobaltite and chalcopyrite. Cf. Kobellite, p. 123.

In the U. S., an argentiferous variety occurs with galena in the mines of the Lillian Mining Co., Printerboy Hill, near Leadville, Colorado.

### 141. STYLOTYPITE. Stylotyp *v. Kobell*, Ber. Ak. München, **1**, 163, 1865.

Orthorhombic; prismatic angle 86½° approx. Twins: cruciform, angle of intersection near 90°.

Fracture imperfectly conchoidal, uneven. Brittle. H. = 3. G. = 4·79. Luster metallic. Color iron-black; streak black.

**Comp.**—$3(Cu_2,Ag_2,Fe)S.Sb_2S_3$, the species being an iron-silver-copper bournonite (ratio $Cu_2 + Ag_2 : Fe = 2 : 1$, and $Cu_2 : Ag_2 = 6 : 1$) = Sulphur 25·0, antimony 31·3, copper 28·3, silver 8·1, iron 7·3 = 100.

**Anal.**—Kobell, l. c.:

S 24·30 Sb 30·53 Cu 28·00 Ag 8·30 Fe 7·00 Pb, Zn *tr.* = 98·13

**Pyr., etc.**—B.B. decrepitates, and fuses very easily. On charcoal a steel-gray globule, which is magnetic; fumes of antimony.

**Obs.**—From Copiapo in Chili.

Named from στῦλος, *column*, and τύπος, *form*, in allusion to the columnar form, in which it differs from tetrahedrite, although approaching it in composition.

A related mineral from the Great Eastern mine, Park county, Colorado, has been examined by Page.

Structure crystalline. H. = 4. G. = 4·89. Color steel-gray. Streak dark red. Analysis

S 26·88 Sb 34·47 Cu 23·20 Pb 1·19 Zn 7·14 Fe 1·38 gangue 5·86 = 100·12

The copper is stated to be present one half as $Cu_2S$, the rest as CuS (Ch. News, **46**, 215, 1882).

DÜRFELDTITE *Raimondi*, Minéraux du Pérou, p. 125, 1878.

In masses with indistinct fibrous structure, also in fine needles. H. = 2·5. G. = 5·40. Color light gray. Luster metallic. Associated with quartz as gangue. After deduction of impurities (31·3 p. c. gangue), the composition is:

S 24·15, Sb 30·52, Pb 25·81, Ag 7·34, Cu 1·86, Fe 2·24, Mn 8·08 = 100.

From the Irismachay mine, Auquimarca, province Cajatambo, Peru. Named after Richard Dürfeldt.

**142. GUITERMANITE.** *Hillebrand*, Proc. Col. Sc. Soc., **1**, 129, 1884.

Massive, compact.

H. = 3. G. = 5·94. Luster metallic. Color bluish gray. Opaque.

**Comp.**—A sulphide of arsenic and lead, $10PbS.3As_2S_3$ or $3PbS.As_2S_3$.

Analysis, after deducting 2·6 lead sulphate, also free sulphur and pyrite, gangue, etc.:

S 19·49 As 14·33 Pb 65·99 Cu 0·19 = 100

The formula $10PbS.3As_2S_3$ requires: S 19·5, As 14·4, Pb 66·1 = 100; but an analysis of purer material is needed to settle the composition. It may prove to conform to the general formula of the preceding group, i.e., $3PbS.As_2S_3$ = Sulphur 20·0, arsenic 15·6, lead 64·4 = 100.

**Obs.**—Occurs intimately mixed with zunyite at the Zuñi mine, near Silverton, San Juan Co. Colorado. Named for Mr. Franklin Guiterman.

**143. TAPALPITE.** *Pedro L. Monroy*, A. del Castillo, Naturaleza, **1**, 76, 1869. Tellurwismuthsilber *Rammelsberg*, Zs. G. Ges., **21**, 81, 1869.

Granular, massive. Sectile, somewhat brittle. G. = 7·803. Luster metallic. Color pale steel-gray, inclining to lead-gray, tarnished.

**Comp.**—A sulpho-telluride of bismuth and silver, perhaps $3Ag_2(S,Te).Bi_2(S,Te)_3$ (if S : Te = 3 : 2) = Tellurium 20·3, sulphur 7·8, bismuth 28·1, silver 43·8 = 100.

**Anal.**—1, Rg., l. c. 2, 3, Genth, Am. Phil. Soc., **24**, 41, 1887, after deducting 7–8 p. c. galena. These analyses vary widely; the above formula is based on those of Genth.

| | | Te | S | Bi | Ag | Cu |
|---|---|---|---|---|---|---|
| 1. | | 24·10 | 3·32 | 48·50 | 23·35 | *tr.* = 99·27 |
| 2. | | 19·76 | 8·07 | 28·41 | 43·76 | — = 100 |
| 3. | G. = 7·74 | 21·67 | 7·25 | 24·99 | 46·09 | — = 100 |

**Pyr.**—Fuses easily in the closed tube, giving a faint white sublimate. B.B. on charcoal gives off fumes and leaves a white and yellow coating; finally yields a silver globule. Dissolved in the cold by nitric acid forming a green solution, which on heating becomes colorless with a white precipitate.

**Obs.**—Occurs at San Antonio mine, San Rafael district, Sierra de Tapalpa, Jalisco, Mexico.

---

Twins: tw. pl. (1) *a*, very common, the axes $\dot{c}$ parallel (f. 6), and *c* the comp. face. (2) *u* ($10\bar{1}4$), also common, the composition-plane usually ⊥ *u*, the axes then being inclined 25° 40′ to each other, sometimes ∥ *u*; repeated, all three faces of *u* as tw. pl. (f. 5), also as twinning lamellæ (in some cases secondary in origin) as shown by fine striations. (3) *r*, not common, the crystals crossing nearly at right angles. (4) *e* ($01\bar{1}2$) rare. Crystals commonly prismatic and hemimorphic[3], as sometimes shown by development of the two ends when distinct; also by the occurrence of *m* as a trigonal prism; also by the unsymmetrical development of striations on *a* due to the form *q* ($16\bar{7}1$). The hemimorphic character is often obscured by twinning. Also massive, compact.

Cleavage: *r* distinct; *e* imperfect. Fracture conchoidal to uneven. Brittle. H. = 2·5. G. = 5·77–5·86; 5·85 if pure. Luster metallic-adamantine. Color black to grayish black, by transmitted light deep-red. Streak purplish red. Nearly opaque, but transparent in very thin splinters. Optically negative. Double refraction strong. Indices, Fizeau (Dx.):

$$\omega = 3{\cdot}084 \qquad \epsilon = 2{\cdot}881$$

**Comp.**—$Ag_3SbS_3$ or $3Ag_2S.Sb_2S_3$ = Sulphur 17·8, antimony 22·3, silver 59·9 = 100. Some varieties contain small amounts of arsenic, see proustite p. 134.

Henckel found arsenic in ruby silver (Pyritol., 169, 1725), and both light and red silver ores were afterwards considered arsenical, until Klaproth's analysis, detecting antimony alone, in 1794 (Beitr., **1**, 141); after this both were supposed to be antimonial, until Proust, in 1804, showed that there were two species, an antimonial and an arsenical. The existence of intermediate compounds is shown by several of the analyses above.

**Pyr., etc.**—In the closed tube fuses and gives a reddish sublimate of antimony oxysulphide; in the open tube sulphurous fumes and a white sublimate of antimony trioxide. B.B. on charcoal fuses with spirting to a globule, coats the coal white, and the assay is converted into silver sulphide, which, treated in O.F., or with soda in R.F., gives a globule of silver. In case arsenic is present it may be detected by fusing the pulverized mineral with soda on charcoal in R.F.

Decomposed by nitric acid with the separation of sulphur and of antimony trioxide.

**Obs.**—Occurs principally with calcite, native arsenic, and galena, at Andreasberg in the Harz; also at Freiberg, Saxony, with proustite, argentite, etc.; Příbram, Bohemia, with argentiferous galena; Schemnitz, Kremnitz, etc., in Hungary; Kajánel, Transylvania; Kongsberg, Norway, with native silver; Gaudalcanal in Spain; in Cornwall. In Mexico it is worked at Guanajuato and elsewhere as an ore of silver. In Chili it is found in crystals with proustite at Chañarcillo near Copiapo.

In Colorado, not uncommon; thus with silver and tetrahedrite in Ruby District, Gunnison Co.; with sphalerite in Sneffle's distr., Ouray Co.; Marshall Creek, San Miguel Co.; near Rico and elsewhere, Dolores Co.; also Clear Creek Co. and near Central City, Gilpin Co. In Nevada, at Washoe in Daney Mine; in Ophir mine, rare; abundant about Austin, Reese river, but no good crystals; at Poorman lode, Idaho, in masses sometimes of several hundred-weight, along with cerargyrite; also at the Monarch and other mines in the Atlanta district. In New Mexico, at Gold Hill near Silver City, Kingston, Sierra Co., with silver, argentite, etc.; Bullard's Peak district, Grant Co. In Utah and Arizona with silver ores at various points.

Named from πῦρ, *fire*, and ἄργυρος, *silver*, in allusion to the color.

**Alt.**—Occurs like proustite, changed to argentite ($Ag_2S$); to pyrite. Also occurs pseudomorph after silver.

**Ref.**—[1] Min. Mag., 8, 37, 1888, and Zs. Kr., **15**, 129, 1888; cf. also Rethwisch, Jb. Min., Beil.-Bd., **4**, 31, 1886: the latter attempted to show a variation in angle between pyrargyrite and proustite corresponding to variation in composition, but this is not confirmed on the specimens examined by Miers and Prior, cf. also Min. Mag., **7**, 196, 1887.

[2] This is chiefly the list of Miers (l. c.), based upon a critical study of the earlier observations of other authors and with many additions; a large number of forms regarded as doubtful are not included here; cf. also Rethwisch, Jb. Min., **2**, 1 ref., 1890. Other lists, also critical, have been given by Rethwisch (l. c.) and Gdt., Index, **3**, 59, 1888. With earlier authors the forms for pyrargyrite and proustite have not been separated. References to the literature are given in full by Rethwisch and by Miers [3] Traube, Kajánel, Jb. Min., **1**, 286, 1890. On the hemimorphic forms and twinning, see Schuster, Zs. Kr., **12**, 117, 1886, also Miers, l. c.

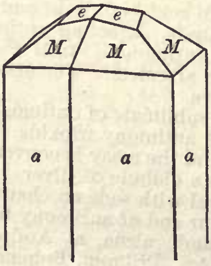
2.



1, Chañarcillo, Streng. 2, Miers.

Twins: tw. pl. (1) *u* ($10\bar{1}4$), common, sometimes as tw. lamellæ; (2) *r*, also common; (3) *c*, (4) *e*, both rare, cf. pyrargyrite. Crystals often acute rhombohedral or scalenohedral. Also massive, compact.

Cleavage: *r* distinct. Fracture conchoidal to uneven. Brittle. H. = 2–2·5. G. = 5·57–5·64; 5·57 if pure. Luster adamantine. Color scarlet-vermilion; streak same, also inclined to aurora-red. Transparent to translucent. Optically negative. Double refraction strong. Dichroism weak $\parallel \dot{c}$ = cochineal-red, $\parallel a$ blood-red. Indices, Fizeau (Dx.):

$\omega_r = 2{\cdot}9789$ Li $\quad \epsilon_r = 2{\cdot}7113$
$\omega_y = 3{\cdot}0877$ Na $\quad \epsilon_y = 2{\cdot}7924$

**Comp.**—$Ag_3AsS_3$ or $3Ag_2S.As_2S_3$ = Sulphur 19·4, arsenic 15·2, silver 65·4 = 100.

**Anal.**—1, Petersen, J. pr. Ch., **106**, 144, 1869. 2, Rethwisch, Jb. Min., Beil.-Bd., **4**, 94, 1886. 3–7, G. T. Prior, Min. Mag., 8, 98, 1888.

| 7. Saxony? | | 19·54 | [12·29] | 3·74 | 64·43 | = 100 |

[a] Probably too high.

**Pyr., etc.**—In the closed tube fuses easily, and gives a faint sublimate of arsenic trisulphide; in the open tube sulphurous fumes and a white crystalline sublimate of arsenic trioxide. B.B. on charcoal fuses and emits odors of sulphur and arsenic; by prolonged heating in O.F., or with soda in R.F., gives a globule of pure silver. Some varieties contain antimony.

Decomposed by nitric acid, with separation of sulphur.

**Obs.**—Occurs at Freiberg, Johanngeorgenstadt, Marienberg, and Annaberg in Saxony; at Joachimsthal in Bohemia; Wolfach in Baden; Markirchen in Alsace; Chalanches in Dauphiné; Guadalcanal in Spain; in Mexico; Peru; Chili, near Copiapo, at Chañarcillo in magnificent crystallizations, some crystals 3 inches long.

In Colorado, Ruby Distr., Gunnison Co.; Sheridan mine, San Miguel Co.; Yankee Girl mine, Ouray Co. In Arizona, with silver ores at various points. In Nevada, in the Daney mine, and in Comstock lode, but rare; in veins about Austin, Lander Co.; in microscopic crystals in Cabarrus Co., N. C., at the McMakin mine; in Idaho, at the Poorman lode, with pyrargyrite, native silver and gold, and cerargyrite.

Named after the French chemist, J. L. Proust (1755–1826).

**Ref.**—[1] Cf. references under pyrargyrite; earlier authors have not attempted to separate the forms characteristic of proustite from those of pyrargyrite.

---

**146. PYROSTILPNITE.** Feuerblende *Breith.*, Char., 285, 333, 1832. Fireblende *Dana*, Min., 543, 1850. Pyrostilpnite, *Dana*, Min., 93, 1868. Pyrichrolite *Adam*, Tabl. Min., 60, 1869. Pyrochrotit *Breithaupt*, Frenzel, Min. Lex. Sachsen, 252, 1874.

Monoclinic. Axes $\grave{a} : \bar{\grave{b}} : \grave{c} = 0{\cdot}35465 : 1 : 0{\cdot}17819$; $\beta = 90° = 100 \wedge 001$ Luedecke[1].

$100 \wedge 110 = 19°\ 31\tfrac{2}{3}'$, $001 \wedge 101 = 26°\ 40\tfrac{1}{2}'$, $001 \wedge 011 = 10°\ 6\tfrac{1}{4}'$.

**Forms:**

In very small crystals, tabular ‖ *c*; sometimes twins with tw. pl. *a* and *c*.

Cleavage: *c* imperfect. Fracture conchoidal. Brittle. H.=2–2·5. G.=5·63. Luster submetallic-adamantine. Color blackish brown to iron-black by reflected light. Translucent and dull honey-yellow to hyacinth-red by transmitted light. Streak orange-yellow.

**Comp.**—A compound of arsenic, selenium, and silver, with 57·7 p. c. Ag, Schrauf, l. c.

**Obs.**—From Joachimsthal, Bohemia, with proustite, argentite, galena. Also from Schemnitz, Hungary, on quartz with pyrargyrite, pyrite, and probably pyrostilpnite. Named after Rittinger, an Austrian mining official.

A mineral from Chañarcillo, Chili, described by Streng (Jb. Min. 917, 1878, 547, 1879) as pyrostilpnite, has the angles of rittingerite (Schrauf, ibid., 144, 1879) and may belong here; for this Streng (Jb. Min., **1**, 57, 1886) suggests the composition $Ag_3As(S,Se)_3$ analogous to pyrostilpnite. Groth places rittingerite near stephanite, basing his conclusion upon the silver percentage given above, and a certain resemblance in form noted by Schrauf.

Isometric; tetrahedral. Observed forms[1]:

*a* (100, *i*-*i*)
*d* (110, *i*)
*o* (111, 1)
$o_,$ ($1\bar{1}1$, − 1)
*f* (310, *i*-3)
*e* (210, *i*-2)[3]
*r* (332, $\frac{3}{2}$)
$\Delta$ (774, $\frac{7}{4}$)[5]
*p* (221, 2)
$\mu$ (411, 4-4)
*m* (311, 3-3)
*n* (211, 2-2)
$\psi$ (955, $\frac{9}{5}$-$\frac{9}{5}$)
$\beta$ (322, $\frac{3}{2}$-$\frac{3}{2}$)?[3]
$r_,$ ($3\bar{3}2$, − $\frac{3}{2}$)
$\phi_,$ ($6\bar{1}1$, − 6-6)
$\omega_,$ ($5\bar{1}1$, − 5-5)?
$\mu_,$ ($4\bar{1}1$, − 4-4)
$n_,$ ($2\bar{1}1$, − 2-2)
$j_,$ ($17\cdot\bar{9}\cdot9$, $\frac{17}{9}$-$\frac{17}{9}$)[4]
*s* (321, 3-$\frac{3}{2}$)
*x* (431, 4-$\frac{4}{3}$)[4]
$v_,$ ($5\bar{2}1$, − 5-$\frac{5}{2}$)
$y_,$ ($6\bar{3}1$, − 6-2)[2]
$z_,$ ($12\cdot\bar{7}\cdot5$, − $\frac{12}{5}$-$\frac{12}{7}$)

Twins[1]: (1) tw. pl. *o*, contact-twins with the comp.-face either ∥ or ⊥ to the tw. pl., and penetration-twins, both common, twinning often repeated; also rarely twins (2) with axes parallel and symmetrical with reference to a cubic plane. Habit tetrahedral; crystals sometimes in parallel position[6], as on chalcopyrite, sphalerite. Also massive; granular, coarse or fine; compact.

Cleavage none. Fracture subconchoidal to uneven. Rather brittle. H. = 3–4·5. G. = 4·4–5·1. Luster metallic, often splendent. Color between flint-gray and iron-black. Streak like color, sometimes inclining to brown and cherry-red. Opaque; sometimes subtranslucent (cherry-red) in very thin splinters.

**Comp., Var.**—For TETRAHEDRITE, essentially $Cu_8Sb_2S_7$ or $4Cu_2S.Sb_2S_3$=Sulphur 23·1, antimony 24·8, copper 52·1 = 100.

For TENNANTITE, essentially $Cu_8As_2S_7$ or $4Cu_2S.As_2S_3$ = Sulphur 25·5, arsenic 17·0, copper 57·5 = 100.

Antimony and arsenic are usually both present and thus these two species graduate into each other and no sharp line can be drawn between them. There are also varieties containing bismuth, chiefly at the arsenical end of the series.

Further the copper is replaced by iron, zinc, silver, mercury, lead, and rarely cobalt and nickel, and in traces tin (Sandb.) and perhaps platinum.

**I. Tetrahedrite.** ANTIMONIAL SERIES.

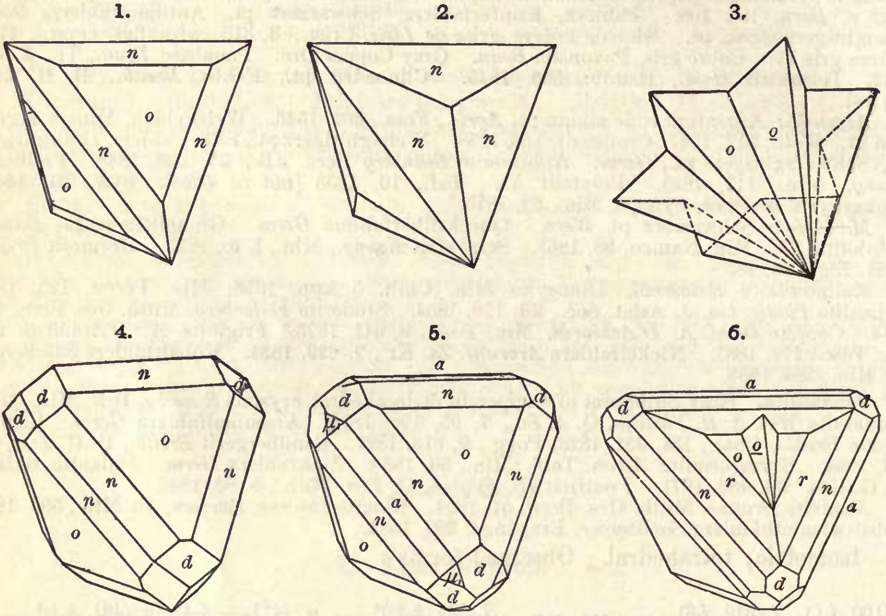
**Var.**—1. *Ordinary;* lichtes Fahlerz *Germ.* Contains little or no silver. Color steel-gray to dark gray and iron-black. G. = 4·75–4·9.

2. *Argentiferous; Freibergite.* Weissgiltigerz *Germ.* Color usually steel-gray, lighter than the ordinary varieties; sometimes iron-black; streak often reddish. G. = 4·85–5·0.

3. *Mercurial; Schwatzite.* Color dark gray to iron-black. Luster often dull. G. = 5·10 chiefly. Breithaupt attempted to distinguish varieties here under the names *spaniolite* and *hermesite.*

4. *Plumbiferous.* Here belongs *malinowskite,* also a variety from Arizona (anal. 34), perhaps also polytelite, p. 141.

Other varieties, more or less closely conforming to the tetrahedrite formula, occur, containing iron, nickel, and cobalt in considerable amount. Platinum occurs in an ore from Guadalcanal, Spain, according to Vauquelin.



Figs. 1, 2, Simple forms. 3, after Sbk. 4, 5, Dillenburg, Cramer. 6, Clausthal, Sbk.

**II. Tennantite.** ARSENICAL SERIES.

**Var.**—1. The original tennantite from Cornwall contains only copper and iron (to 9·75 p. c., Phillips). In crystals, habit dodecahedral, also cleavage *d* in traces. G. = 4·37–4·49. Color blackish lead-gray to iron-black.

2. *Kupferblende Germ., Sandbergerite.* Contains zinc in considerable amount.

*Fredricite* from Sweden has, besides copper, also iron, lead, silver, and tin.

*Rionite* and *annivite* carry bismuth in considerable amount as well as antimony. The *wismuthkobaltfahlerz* of Sandberger with bismuth has also cobalt.

**Pyr., etc.**—Differ in the different varieties. In the closed tube all the antimonial kinds fuse and give a dark red sublimate of antimony oxysulphide; when containing mercury, a faint dark gray sublimate appears at a low red heat; and if much arsenic, a sublimate of arsenic trisulphide first forms. In the open tube fuses, gives sulphurous fumes and a white sublimate of antimony; if arsenic is present, a crystalline volatile sublimate condenses with the antimony; if the ore contains mercury it condenses in the tube in minute metallic globules. B.B. on charcoal fuses, gives a coating of the oxides of antimony and sometimes arsenic, zinc, and lead; the arsenic may be detected by the odor when the coating is treated in R.F.; the oxide of zinc assumes a green color when heated with cobalt solution. The roasted mineral gives with the fluxes reactions for iron and copper; with soda yields a globule of metallic copper. To determine the presence of a trace of arsenic by the odor, it is best to fuse the mineral on charcoal with soda. The presence of mercury is best ascertained by fusing the pulverized ore in a closed tube with about three times its weight of dry soda, the metal subliming and condensing in minute globules. The silver is determined by cupellation.

Decomposed by nitric acid, with separation of sulphur and antimony trioxide.

**Obs.**—*Tetrahedrite* is often associated with chalcopyrite, pyrite, sphalerite, galena, and various other silver, lead, and copper ores; also siderite. It occurs at many Cornish mines; thus at the Herodsfoot mine, Liskeard, in tetrahedral crystals often coated with iridescent chalcopyrite; at the Levant mine near St. Just; the Condurrow mine; near St. Austell. Prominent localities are Andreasberg and Clausthal in the Harz; Freiberg in Saxony; Dillenburg and Horhausen in Nassau; at Müsen; various mines in the Black Forest; Kahl in the Spessart; Přibram in Bohemia; Kogel near Brixlegg in Tyrol; Kapnik, Kremnitz, and Herrengrund in Hungary; Baigorre near St. Etienne in the Pyrenees. In Mexico, at Durango, Guanajuato; Chili; Bolivia, etc. The *argentiferous* variety occurs especially at Freiberg; Přibram; the Foxdale mine, Isle of Man; Huallanca in Peru and elsewhere in South America and Mexico. The *mercurial* variety at Schmölnitz, Hungary; Poratsch, Zavatka, and Kotterbach near Iglo; Schwatz in Tyrol; and the valleys of Angina and Castello in Tuscany. *Coppite* and *frigidite* are from the mines in the Val del Frigido, in the Apuan Alps. *Studerite* is from Ausserberg, Ober-Wallis, Switzerland; named after Prof. Bernhard Studer.

In the U. S., tetrahedrite occurs at the Kellogg mines, 10 m. N. of Little Rock, Arkansas, with galena. In Colorado, near Central City, Gilpin Co., in fine crystals, often in parallel position coating chalcopyrite; also in Clear Creek and Summit Cos.; the Ulay mine, Lake Co.; further in Hinsdale, San Juan, Ouray, and Miguel Cos.; with pyrargyrite in Ruby District, Gunnison Co. In Nevada, abundant at the Sheba and De Soto mines, Humboldt Co., massive and rich in silver (the De Soto containing 16·4 p. c. of silver, Allen); near Austin in Lander Co.; Isabella mine, Reese river. In Utah. In Arizona at the Heintzelman mine, containing 1½ p. c. of silver; at the Santa Rita mine; at various points in British Columbia.

*Tennantite* has been found at the Cornish mines, particularly at Wheal Jewel in Gwennap, and Wheel Unity in Gwinear, usually in splendent crystals investing other copper ores; also at the East Relistian mine; at Freiberg (Kupferblende); at the Wilhelmine mine in the Spessart. Also at Skutterud in Norway. At Capelton, Pr. Quebec, Canada. Named after the chemist, Smithson Tennant (1761–1815). See further p. 1049.

*Julianite* is from the Friedrich-Julian mine, at Rudelstadt, Silesia. *Annivite* from the Val d'Anniviers, Switzerland. *Fredricite* from Falun, Sweden.

**Alt.**—Chalcopyrite, malachite, azurite, amalgam, bournonite, erythrite, cinnabar, covellite, occur as pseudomorphs after tetrahedrite.

**Artif.**—Obtained by Durocher in tetrahedral crystals and of varying composition. C. R., 32. 823, 1851.

Occurs as a recent formation at Plombières and at Bourbonne-les-Bains (Daubrée).

**Ref.**—[1] Sadebeck, monograph with authorities, description of methods of twinning, etc., Zs. G. Ges., **24**, 427, 1872. [2] Slg., Horhausen, Zs. Kr., **1**, 335, 1877. [3] Groth, Min.-Samml., 66, 1878. [4] Cathrein, Brixlegg, Zs. Kr., **9**, 353, 1884, Min. Mitth., **10**, 56, 1888. [5] Rath, Bolivia, Ber. nied. Ges., June 7, 1886. [6] Sbk, l. c., also Becke, Min. Mitth., **5**, 331, 1882.

Nepaulite *H. Piddington*, J. Asiat. Soc., **23**, 170, 1854. Described as a carbonate of bismuth, copper, etc.; shown by Mallet (Rec. G. Surv. India, **18**, 235, 1885, Min. India, 30, 1887) to be simply tetrahedrite. From near Khatmandu, Nepál.

Fieldite. An ore from mine Altar, 30 leagues from Coquimbo, afforded F. Field (J. Ch. Soc., **4**, 332, 1851), S 30·35, As 3·91, Sb 20·28, Cu 36·72, Zn 7·26, Fe 1·23, Ag 0·075, Au 0·003. It is soft, of greasy appearance, greenish-gray, slightly reddish, with powder bright red. Domeyko considers it impure with sphalerite, pyrite, and galena. Ettling observes (ib., **6**, 140, 1854) that the constitution is analogous rather to enargite than tetrahedrite. Kenngott has named it *Fieldite.*

Polytelite *Glock.*, Syn., 31, 1847. Weissgültigerz *Germ.* pt. Consists mainly of lead, silver, antimony, and sulphur. Glocker cites the following analysis by Rammelsberg (Pogg., **68**, 515, 1846) of an ore from the Hoffnung Gottes mine near Freiberg, a fine-granular ore, having G. = 5·438–5·465, apparently homogeneous but somewhat mixed with sphalerite and pyrite. Klaproth also analyzed a related *weissgültigerz* from the Himmelsfürst mine near Freiberg (Beitr., **1**, 166, 1795; cf. 5th Ed., p. 104). Analysis, Rg.:

S 22·53 Sb [22·39] Cu 0·32 Fe 3·83 Zn 6·79 Pb 38·36 Ag 5·78 = 100

Rammelsberg makes the mineral, from his analysis, a silver-lead tetrahedrite, with the formula $4(Pb,Ag,Fe,Zn)S.Sb_2S_3$, in which the ratio Fe : Zn : Pb + Ag = 2 : 3 : 6, and Pb : Ag = 7 : 1. Cf. malinowskite, p. 137.

Clayite *W. J. Taylor*, Proc. Ac. Philad., p. 306, Nov. 1859. In tetrahedrons with dodecahedral planes. Crystals small. Also massive, incrusting. H. = 2·5. Luster metallic. Color and streak blackish lead-gray. Opaque. Analysis—W. J. Taylor:

S 8·22 As 9·78 Sb 6·54 Pb 68·51 Cu 7·67 Ag *trace* = 100·72

From Peru. Probably a result of alteration. Requires further investigation. Named after Messrs. Joseph A. Clay and J. Randolph Clay.

---

### 150. JORDANITE. *Rath*, Ber. nied. Ges., **21**, 34, 1864; Pogg., **122**, 387, 1864.

Orthorhombic. Axes $\breve{a} : \bar{b} : \dot{c} = 0·53747 : 1 : 2·0305$ Rath[1].

$100 \wedge 110 = 28° 15\frac{1}{3}'$, $001 \wedge 101 = 75° 10\frac{1}{2}'$, $001 \wedge 011 = 63° 46\frac{5}{6}'$.

Twins: tw. pl. $m$, common; often repeated, producing pseudo-hexagonal forms, like those of aragonite. Crystals six-sided with $c$ predominating, sometimes tabular; the pyramidal planes narrow and often striated.

Cleavage: *b* distinct. Fracture conchoidal. Brittle. H. = 3. G. = 6·393. Luster metallic. Color lead-gray. Streak black. Opaque.

**Comp.**—$Pb_4As_2S_7$ or $4PbS.As_2S_3$ = Sulphur 18·7, arsenic 12·5, lead 68·8 = 100.

**Anal.**—1, Sipöcz, Min. Mitth., 29, 1873. 2, Ludwig, ib., p. 216, material containing a little galena.

| | | S | As | Sb | Pb | |
|---|---|---|---|---|---|---|
| 1. Binnenthal | G. = 6·393 | $\frac{2}{2}$ 18·16 | 12·71 | 0·11 | 69·97 | = 100·95 |
| 2. Nagyág | | 17·06 | 9·90 | 1·87 | 70·80 | = 99·63 |

**Pyr.**—Cf. sartorite.

**Obs.**—From Imfeld in the Binnenthal in cavities in a crystalline dolomite with the related minerals dufrenoysite, sartorite, binnite, also sphalerite, etc. With sphalerite and galena at Nagyág in Transylvania.

Named after Dr. Jordan of Saarbrück.

**Ref.**—[1] Pogg., **122**, 387, 1864, and ib. Erg.-Bd., **6**, 363, 1873. [2] Tsch., Nagyág, Min. Mitth., 215, 1873. [3] Lewis, Binnenthal, Zs. Kr., **2**, 191, 1878. See p. 1039.

### 151. MENEGHINITE. *Bechi*, Am. J. Sc., **14**, 60, 1852.

Orthorhombic. Axes $\breve{a} : \bar{b} : \grave{c}$ = 0·52891 : 1 : 0·36317 Miers[1].
$100 \wedge 110 = 27° 52' 29''$, $001 \wedge 101 = 34° 28' 30''$, $001 \wedge 011 = 19° 57' 34''$.

Bottino, after Miers.

Crystals slender prismatic, vertically striated. Also massive, fibrous to compact.

Cleavage: *a* perfect, but interrupted; *c* difficult. Fracture conchoidal. Brittle. H. = 2·5. G. = 6·34–6·43; 6·399 Miers, 6·432 Loczka. Luster metallic, bright. Color blackish lead-gray. Streak black, shining. Opaque.

**Comp.**—$Pb_4Sb_2S_7$ or $4PbS.Sb_2S_3$ = Sulphur 17·4, antimony 18·6, lead 64·0 = 100. Copper is usually present in small amount.

**Anal.**—1, E. Bechi, l. c. 2, Rath, Pogg., **132**, 376, 1867. 3, Martini & Funaro, Att. Soc. Tosc., **2**, 116, 1876. 4, Loczka, Földt. Közl., **13**, 356, 1883. 5, 6, Frenzel, Pogg., **141**, 443, 1870. 7, B. J. Harrington, Trans. R. Soc. Canada, **1**, 79, 1883.

**Pyr.**—Like zinkenite.

**Obs.**—Occurs at Bottino, near Serravezza, in Tuscany, with galena, boulangerite, jamesonite, etc., and also crystals of albite; also in the neighboring valley of Castello. From the Ochsenkopf near Schwarzenberg, Saxony, disseminated through emery; at Goldkronach. Also with quartz and dolomite as a vein in gneiss at Marble Lake, Barrie township, Ontario, Canada.

First observed by Prof. Meneghini, of Pisa (1811–1889), after whom it was named.

**Ref.**—[1] Bottino, Min. Mag., **5**, 325, 1884; Krenner (Földt. Közl., **13**, 297, 350, 1883) obtained nearly the same results. Rath made the species monoclinic, Pogg., **132**, 372, 1867. Cf. also Schmidt, Zs. Kr., **8**, 613, 1884; Hintze, ib., **9**, 294, 1884. The position of Miers is here retained.

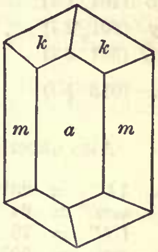
**152. GEOCRONITE.** Geokronit *Svanberg*, Ak. H. Stockholm, 184, 1839. Schulzit *Hausm.*, Handb., 166, 1847.

Orthorhombic. Axes $\breve{a} : \bar{b} : \dot{c} = 0{\cdot}5805 : 1 : 0{\cdot}5028$ Kerndt[1].

$100 \wedge 110 = {}^*30° \ 8'$, $001 \wedge 101 = 40° \ 54'$, $001 \wedge 011 = 26° \ 41\frac{1}{2}'$.

**Forms:** *a* (100, *i*-$\bar{i}$); *m* (110, *I*); *k* (211, 2-$\bar{2}$).

Angles: $mm''' = 60° \ 16'$, $kk = 114° \ 16'$, $kk'' = {}^*122°$, $kk''' = 28° \ 13'$



Kerndt.

Crystals rare. Usually massive; granular and earthy.

Cleavage: *m* distinct; *k* less so. Fracture uneven. H. = 2·5. G. = 6·3–6·45. Luster metallic. Color and streak light lead-gray to grayish blue. Opaque.

**Comp.**—$Pb_5Sb_2S_8$ or $5PbS.Sb_2S_3$ = Sulphur 16·7, antimony 15·7, lead 67·6 = 100. Part of the antimony may be replaced by arsenic, and the lead by copper.

**Anal.**—1, Svanberg, l. c. 2, Sauvage, Ann. Mines, **17**, 525, 1840. 3, Kerndt, Pogg., **65**, 302, 1845. 4, Nauckhoff, G. För. Förh. **1**, 88, 1872.

| 4. Björkskogsnäs | G. = 6·26 | 17·73 | 17·33 | — | 57·95 | 5·93 | 0·11 | = 99·05 |

**Pyr.**—Same as for zinkenite.

**Obs.**—From the silver mines of Sala in Sweden; also in a fine crystalline dolomite at Björkskogsnäs, Örebro; from Galicia, Merido in Spain, in nodules in galena; Val di Castello near Pietro Santo, in Tuscany. Also at Owen's Valley, Inyo Co., Cal.

The name geocronite is derived from *γῆ*, *earth*, and *Κρόνος*, *Saturn*, the alchemistic name for lead.

A mineral found at Tinder's gold mine, Louisa Co., Va., may be this species. It contains, according to Genth (Am. J. Sc., **19**, 9, 1855), S 16, Pb 60, Ag 0·25, with antimony and arsenic. G. = 6·393.

An antimonial ore from between La Paz and Yungas, in Bolivia, is referred here by D. Forbes (Phil. Mag., **29**, 9, 1865).

**Ref.**—[1] From Val di Castello, Pogg., **65**, 302, 1845.

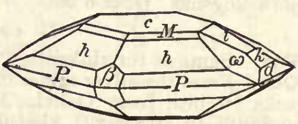
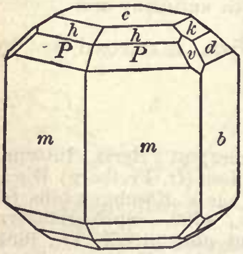
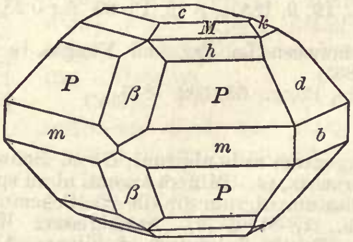
3.



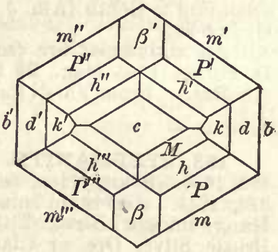
4.



5.



6.



Figs. 1, 2, Simple forms. 3, Přibram. 4, Andreasberg. 5, 6, Přibram. 3–6, Vrba.

Twins: tw. pl. (1) $m$, often repeated, hence pseudo-hexagonal; (2) $\pi$ (130); (3) $a$ or $b$, and comp.-face $c$, observed in hemimorphic crystals. Crystals usually short prismatic ‖ $\dot{c}$; also elongated ‖ $\breve{a}$, and tabular ‖ $c$. Hemimorphism[3] shown by want of symmetry in striations on $m$ ‖ edge $m/\Gamma$. Also massive, compact and disseminated.

Cleavage: *b*, *d* imperfect. Fracture subconchoidal to uneven. Brittle. H. = 2–2·5. G. = 6·2–6·3. Luster metallic. Color and streak iron-black. Opaque.

**Comp.**—$Ag_5SbS_4$ or $5Ag_2S.Sb_2S_3$ = Sulphur 16·3, antimony 15·2, silver 68·5 = 100.

**Anal.**—1, Frenzel, Jb. Min., 788, 1873. 2, Kolár, Zs. Kr., **5**, 435, 1881. Also 5th Ed., p. 106.

| | | S | Sb | Ag |
|---|---|---|---|---|
| 1. Freiberg | G. = 6·28 | 16·49 | 15·76 | 68·64 = 100·89 |
| 2. Přibram | G. = 6·271 | 15·61 | 16·48 | 67·81 Cu, Fe *tr*. = 99·90 |

**Pyr.**—In the closed tube decrepitates, fuses, and after long heating gives a faint sublimate of antimony oxysulphide. In the open tube fuses, giving off antimonial and sulphurous fumes. B.B. on charcoal fuses with projection of small particles, coats the coal with antimony trioxide, which after long blowing is colored red from oxidized silver, and a globule of metallic silver is obtained.

Soluble in dilute heated nitric acid, sulphur and antimony trioxide being deposited.

**Obs.**—In veins, with other silver ores, at Freiberg, Schneeberg, and Johanngeorgenstadt in Saxony (see Frenzel, Min. Lex. Sachs.); at Přibram and Ratieborzitz in Bohemia; at Schemnitz and Kremnitz in Hungary; at Andreasberg in the Harz; Kongsberg, Norway; Wheal Newton, Cornwall; Zacatecas and Guanajuato in Mexico; in Peru; Chañarcillo, Chili.

In Nevada, a rather abundant silver ore in the Comstock lode; at Ophir and Mexican mines in fine crystals; in the Reese river and Humboldt and other regions. In Idaho, at the silver mines at Yankee Fork, Queen's River district and elsewhere.

Named after the Archduke Stephan, Mining Director of Austria.

**Alt.**—Crystals occur altered to silver.

**Ref.**—[1] Přibram, Ber. Böhm. Ges., p. 119, 1886; closely similar results were obtained by Haidinger, Min. Mohs, **2**, 588, 1824; Schröder, Andreasberg, Pogg., **95**, 258, 1855; Morton, Kongsberg. Zs. Kr., **9**, 239, 1884.

## 156. POLYBASITE.

Sprödglaserz pt. *Wern.* Polybasit *H. Rose*, Pogg., **15**, 573, 1829. Eugenglanz *Breith.*, Char., 266, 1832.

Orthorhombic. Axes $\breve{a} : \bar{b} : \grave{c} = 0·5793 : 1 : 0·91305$ Miers[1].

100 ∧ 110 = 30° 5′, 001 ∧ 101 = 57° 36$\frac{1}{3}$, 001 ∧ 011 = 42° 23$\frac{5}{6}$′.

**Forms:** *c* (001, *O*); *m* (110, *I*); *w* (019, $\frac{1}{9}$-ĭ), *n* (011, 1-ĭ), *t* (021, 2-ĭ); *r* (112, $\frac{1}{2}$), *p* (111, 1), *s* (221, 2).

*mm‴* = *60° 10′ *cr* = 42° 19½′ *rr′* = 71° 16′ *rr‴* = 39° 27′
*ww′* = 11° 35′ *cp* = *61° 14′ *pp′* = 98° 40′ *pp‴* = 52° 8′
*nn′* = 84° 48′ *cs* = 74° 39′ *ss′* = 113° 7′ *ss‴* = 57° 49′

In short six-sided tabular prisms, with beveled edges; *c* faces with triangular striations; in part repeated twins with tw. pl. *m*.

Cleavage: *c* imperfect. Fracture uneven. H. = 2–3. G. = 6·0–6·2. Luster metallic. Color iron-black, in thin splinters cherry-red. Streak black. Nearly opaque. Ax. pl. ∥ *a*. Bx ⊥ *c*. Ax. angle variable, 2E = 62° 44′, 78°, 88° 15′, Dx[2].

**Comp.**—$Ag_9SbS_6$ or $9Ag_2S.Sb_2S_3$ = Sulphur 15·0, antimony 9·4, silver 75·6 = 100. Part of the silver is replaced by copper, e.g., Ag : Cu = 8 : 1; also arsenic replaces antimony.

**Anal.**—1, H. Rose, l. c. 2, 3, Id., ibid., **28**, 156, 1833. 4, C. A. Joy, Rg., Min. Ch., 102, 1860. 5, Tonner [Lotos, 85, 1859], Jb. Min., 716, 1860. 6, Genth, Am. Phil. Soc., **23**, 39, 1886.

| | | S | Sb | As | Ag | Cu | Fe | Zn | |
|---|---|---|---|---|---|---|---|---|---|
| 1 Durango Mexico | | 17·04 | 5·09 | 3·74 | 64·29 | 9·93 | 0·06 | — | = 100·15 |
| 2. Schemnitz | | 16·83 | 0·25 | 6·23 | 72·43 | 3·04 | 0·33 | 0·59 | = 99·70 |
| 3. Freiberg | | 16·35 | 8·39 | 1·17 | 69·99 | 4·11 | 0·29 | — | = 100·30 |
| 4. Cornwall | | 15·87 | 5·46 | 3·41 | 72·01 | 3·36 | 0·34 | — | = 100·45 |
| 5. Přibram | G. = 6·03 | 15·55 | 11·53 | — | 68·55 | 3·36 | 0·14 | — | = 99·13 |
| 6. Colorado | G. = 6·01 | [16·70] | 10·18 | 0·78 | 62·70 | 9·57 | 0·07 | — | = 100 |

**Pyr., etc.**—In the open tube fuses, gives sulphurous and antimonial fumes, the latter forming a white sublimate, sometimes mixed with crystalline arsenic trioxide. B.B. fuses with spirting to a globule, gives off sulphur (sometimes arsenic), and coats the coal with antimony trioxide; with long-continued blowing some varieties give a faint yellowish white coating of zinc oxide, and a metallic globule, which with salt of phosphorus reacts for copper, and cupelled with lead gives pure silver. Decomposed by nitric acid.

**Obs.**—Occurs in the mines of Guanajuato and Guadalupe y Calvo in Mexico; also at Guarisamez in Durango, with chalcopyrite and calcite; at Tres Puntos, desert of Atacama, Chili; at Freiberg and Přibram. In Nevada, at the Reese mines and at the Comstock Lode; in Idaho, at the silver mines of the Owhyhee district. In Colorado, at the Terrible Lode, Clear Creek Co., with argentiferous galena and pyrite. In Arizona, at the Silver King mine.

Named from πολύς, *many*, and βάσις, *base*, in allusion to the many metallic bases present.

**Alt.**—Stephanite and pyrite occur as pseudomorphs after polybasite.

**Ref.**—[1] Min. Mag., 8, 204, 1889. [2] N. R., 85, 1867.

## 157. POLYARGYRITE.

*Sandberger*, Jb. Min., 310, 1869. *Petersen*, Pogg., **137**, 386, 1869.

Isometric. In cubo-octahedrons, usually distorted and indistinct; *d* (110, *i*), *x* (*hll*, *m-m*) also observed.

Cleavage: cubic. Fracture uneven. Malleable and sectile. H. = 2·5. G. = 6·974. Luster metallic. Color iron-black to blackish gray. Streak black. Opaque.

**Comp.**—$Ag_{24}Sb_2S_{15}$ or $12Ag_2S.Sb_2S_3$ = Sulphur 14·5, antimony 7·4, silver 78·2 = 100.

**Anal.**—Petersen, l. c.

| | S | Sb | Ag | Pb | Fe | Zn |
|---|---|---|---|---|---|---|
| G. = 6·974 | 14·78 | 6·98 | 76·70[a] | *tr.* | 0·36 | 0·30 = 99·12 |

[a] Mean of 76·63 and 76·77; another sample gave 78·85 p. c.

**Pyr.**—B.B. on charcoal fuses easily to a black globule, giving off antimonial fumes, and yielding a brittle globule of silver. Soluble with difficulty in nitric acid with separation of sulphur, readily by fuming acid.

**Obs.**—Occurs at Wolfach in Baden with argentite, etc.

---

## II. Sulpharsenates, Sulphantimonates, etc.

### Enargite Group.

| | | | | |

**Pyr.**—In the closed tube decrepitates, and gives a sublimate of sulphur; at a higher temperature fuses, and gives a sublimate of sulphide of arsenic. In the open tube, heated gently, the powdered mineral gives off sulphurous and arsenical fumes, the latter condensing to a sublimate containing some antimony trioxide. B.B. on charcoal fuses, and gives a faint coating of the oxides of arsenic, antimony, and zinc; the roasted mineral with the fluxes gives a globule of metallic copper. Soluble in aqua regia.

**Obs.**—From Morococha, Cordilleras of Peru, at a height of 15,000 feet, in large masses, occasionally with small druses of crystals, along with tennantite, embedded in crystalline limestone; Cordilleras of Chili (*guayacanite*); mine of Hediondas, Prov. Coquimbo; mines of Santa Anna, U. S. of Colombia, in cavities in quartz; Argentine Republic at several mines in the Sierra de Famatina, also in the province of Catamarca; at Cosihuirachi in Mexico. In twin crystals at Matzenköpfl, Brixlegg, Tyrol; and in similar twins from Mancayan, island of Luzon.

In the U. S., at Brewer's gold mine, Chesterfield district, S. Carolina; in Colorado, at mines near Black Hawk and Central City, Gilpin Co.; in Park Co., at the Missouri mine; also on Red mountain in San Juan and Ouray counties. In southern Utah at the Shoebridge mine in crystals and massive; also massive, cleavable at the Mammoth and American Eagle mines in the Tintic district, where it appears as the parent mineral of a number of copper arsenates; at several mines near Butte, Montana, associated with chalcocite, bornite, etc. Morning Star mine, Alpine county, California.

**Ref.**—[1] Pogg., **92**, 237, 1854. [2] Dauber, Peru. l. c., he adds as doubtful (310), (210), (130), (403), (132), but see below. [3] Zeph., Brixlegg, Zs. Kr., 3, 600, 1879. [4] Rath, Argentine Repub., ib., **4**, 426, 1880. [5] Zettler, Luzon, Jb. Min., **1**, 159 ref., 1880.

LAUTITE *Frenzel*, Min. Mitth., 3, 515; **4**, 97, 1881. Described as having the composition (Cu,Ag)AsS, from Lauta, near Marienberg, Saxony. Later shown to be a mechanical mixture of arsenic with a mineral near enargite, cf. Weisbach, Jb. Min., **2**, 250, 1882.

LUZONITE *Weisbach*, Min. Mitth., 257, 1874.

Massive with uneven fracture. Brittle. H. = 3·5. G. = 4·42. Luster metallic. Color dark reddish steel-gray. Streak black.

**Comp.**—$Cu_3AsS_4$ or $3Cu_2S.As_2S_5$ like enargite, with which it is regarded as being dimorphous.

Analysis.—Winkler, l. c.

S 33·14 As 16·52 Sb 2·15 Cu 47·51 Fe 0·93 = 100·25

**Obs.**—Occurs in the copper veins of Mancayan, district of Lepanto, Island of Luzon, associated with the following minerals, named in the order of their deposition: quartz, pyrite (luzonite), enargite, quartz, tetrahedrite, barite. See p. 1041.

CLARITE *Sandberger*, Jb. Min. 960, 1874; 382, 1875. Another mineral having the composition of enargite. Regarded as monoclinic with cleavage *a*, *b*. In tufted groups of crystals. H. = 3·5. G. = 4·46. Luster metallic. Color dark lead-gray. Analysis.—Petersen:

S 32·92 As 17·74 Sb 1·09 Cu 46·29 Fe 0·83 Zn *tr.* = 98·87

Occurs on barite at the Clara mine, near Schapbach, Baden. Sometimes altered to chalcopyrite and covellite.

Note also remarks under binnite, p. 119.

**159. FAMATINITE.** *Stelzner*, Min. Mitth., 242, 1873.

Orthorhombic; isomorphous with enargite. Observed forms[1]: *a*, *c*, *m*, *l*. Also massive, sometimes reniform.

Fracture uneven. Rather brittle. H. = 3·5. G. = 4·57. Color gray with a tinge of copper-red. Streak black. Opaque.

**Comp.**—$Cu_3SbS_4$ or $3Cu_2S.Sb_2S_5$ = Sulphur 29·3, antimony 27·4, copper 43·3 = 100. Arsenic replaces the antimony in part.

**Anal.**—1, 2, Siewert, Min. Mitth., 242, 1873. 3*a*, Frenzel, Jb. Min., 679, 1875. 3*b*, id., after deducting 13·8 pyrite assumed to be present.

| | | | S | Sb | As | Cu | Fe | Zn | Gangue | |
|---|---|---|---|---|---|---|---|---|---|---|
| 1. | Mej. Upulungos mine | G. = 4·59 ⅔ | 29·17 | 21·23 | 4·07 | 44·12 | 0·82 | 0·59 | — | = 100 |
| 2. | Mej. Verdiona mine | G. = 4·52 ⅔ | 29·63 | 20·54 | 3·63 | 45·34 | 0·51 | 0·59 | 0·63 | = 100·87 |
| 3*a*. | Peru | | 33·46 | 10·93 | 7·62 | 41·11 | 6·43 | — | — | = 99·55 |
| 3*b*. | " | | 30·45 | 12·74 | 8·88 | 47·93 | — | — | — | = 100 |

**Pyr.**—In the closed tube decrepitates, giving off sulphur readily, and on stronger heating also some sulphide of antimony. On charcoal gives off white fumes of antimony, leaving a black, brittle metallic globule.

**Obs.**—Occurs with enargite, chalcopyrite, pyrite, etc., in the Sierra de Famatina, Argentine Republic. Also found at Cerro de Pasco, Peru.

**Ref.**—[1] Rath, Zs. Kr., 4, 426, 1880, Ber. nied. Ges., Nov. 4, 1878. See p. 1041.

---

**160. XANTHOCONITE.** Xanthokon *Breith.*, J. pr. Ch., 20, 67, 1840.

Rhombohedral. Axis $\dot{c}$ = 2·3163; *cr* = *69° 30′, *rr*′ = 108° 25′ Breith.[1] Observed forms: *c* (0001, *O*), *r* (10$\bar{1}$0, *R*), *e* (02$\bar{2}$1, − 2). *ce* = 79° 25′. In thin tabular crystals. Also reniform masses with granular structure.

Cleavage: *c*, *r*. Brittle. H. = 2. G. = 5·0–5·2; 4·11–4·16 Breith. Luster adamantine. Color orange-yellow to dull red or clove-brown. Streak yellow. Transparent to translucent.

**Comp.**—$Ag_3AsS_4$ or $3Ag_2S.As_2S_5$=Sulphur 24·3, arsenic 14·3, silver 61·4 = 100.

**Anal.**—Plattner, Pogg., 64, 275, 1845.

| | S | As | Ag | Fe | |
|---|---|---|---|---|---|
| 1. *Brown* | 21·36 | [13·49] | 64·18 | 0·97 | = 100 |
| 2. *Yellow* | 21·80 | [14·32] | 63·88 | — | = 100 |

**Pyr.**—In the closed tube, at a gentle heat, the yellow color is changed to dark red, but on cooling it regains its original color; at a higher temperature fuses, and gives a faint sublimate of sulphide of arsenic. In the open tube, and on charcoal, behaves like proustite.

**Obs.**—Occurs with stephanite at the Himmelsfürst mine near Freiberg.

Named in allusion to its yellow powder, from ξανθός, *yellow*, and κονις, *powder*.

**Ref.**—[1] Pogg., 64, 272, 1845.

**161. EPIBOULANGERITE.** *M. Websky*, Zs. G. Ges., 21, 747, 1869.

Orthorhombic? occurring in striated prismatic needles. G. = 6·309. Luster metallic. Color dark bluish gray, almost black. Structure granular, acicular.

**Comp.**—$Pb_3Sb_2S_8$ or $3PbS.Sb_2S_5$=Sulphur 21·5, antimony 23·0, lead 55·5=100.

**Anal.**—1, 2, Websky:

| | S | Sb | Pb | Ni | Fe | Zn | |
|---|---|---|---|---|---|---|---|
| 1. Granular | 21·89 | 20·77 | 56·11 | 0·20 | 0·60 | 0·29 | = 99·86 |
| 2. Needles | 21·31 | 20·23 | 54·88 | 0·30 | 0·84 | 1·32 | = 98·88 |

Websky considers the mineral as probably a product of the decomposition of boulangerite from which it differs in containing more sulphur and correspondingly less antimony

**Obs.**—Found with galena, pyrite, sphalerite, and arsenopyrite at Altenberg in Silesia

**162. EPIGENITE.** Arsenwismuthkupfererz *Sandberger*, Jb. Min., 415, 1868. Epigenit *Id.*, ibid., 205, 1869.

Orthorhombic. In short prisms (69° 10′) with macrodome and brachydome, resembling arsenopyrite.

Fracture uneven. H. = 3·5. Luster metallic. Color steel-gray. Streak black. Opaque.

**Comp.**—Perhaps (Groth) $R_7As_2S_{12}$ with $R_7 = 4Cu_2 + 3Fe$, or $4Cu_2S.3FeS.As_2S_5$ = Sulphur 31·5, arsenic 12·3, copper 41·5, iron 14·7 = 100.

**Anal.**—Petersen, Pogg., **136**, 502, 1869, after deducting 5 p. c. wittichenite.

S 32·34 As 12·78 Cu 40·68 Fe 14·20 = 100

**Pyr.**—In the closed tube gives first sulphur, then sulphide of arsenic. B.B. on charcoal gives an arsenic reaction and a magnetic slag with copper globules. Soluble in nitric acid with separation of sulphur.

**Obs.**—Occurs sparingly at Neuglück mine in the Böckelsbach at Wittichen, Baden. So named from ἐπιγίγνεσθαι, *to follow after*, because always observed implanted upon the barite vein masses.

Regnolite *A. D'Achiardi*, I Metalli, **1**, 293, 294, 1883. Nuovo Cimento, **3**, May 1870. In tetrahedral crystals resembling (as it does in other characters) the sandbergerite with which it is associated.

Analysis:

S 37·45 As 15·23 Cu 33·25 Ag 0·04 Fe 5·66 Zn 7·72 Pb *tr.* = 99·35

Calculated composition essentially $Cu_7As_2S_{12}$ or $5CuS.FeS.ZnS.As_2S_5$ = Sulphur 39·5, arsenic 15·4, copper 32·6, iron 5·8, zinc 6·7 = 100.

From the Jucud mines near the source of the Jucud river, Cajamarca, Peru. Named after Dr. Carlo Regnoli.

---

**163. ARGYRODITE.** *Weisbach*, Jb. Berg.-Hütt., 1886; Jb. Min., **2**, 67, 1886.

Monoclinic. Axes: $\grave{a} : \bar{b} : \grave{c} = 0·6780 : 1 : 0·6144$; $\beta = 70° = 001 \wedge 100$ Weisbach[1].

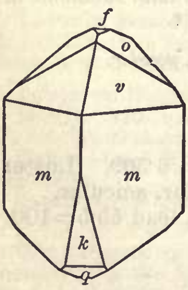
$100 \wedge 110 = 32° 30'$, $001 \wedge 101 = 33° 1\frac{1}{2}'$, $001 \wedge 011 = 30°$.

**Forms:** *m* (110, *I*), *f* ($\bar{1}03$, $\frac{1}{3}$-$\bar{i}$), *q* ($\bar{1}01$, 1-$\bar{i}$), *k* ($\bar{6}01$, 6-$\bar{i}$), *o* (011, 1-$\grave{i}$), *v* (232, $-\frac{3}{2}$-$\frac{3}{2}$)?, *n* ($\bar{6}91$, 9-$\grave{\frac{3}{2}}$)?.

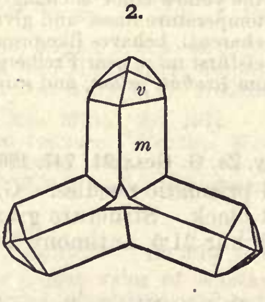
Angles: $mm''' = *65°$, $oo' = *60°$, $vv' = 58°$ (meas 50°), $mv = 31° 49'$, edge $m/m'' \wedge o/o' = *110°$, $\wedge v/v' = 143° 2'$ (141°), $\wedge k' = 169° 33'$ (170°), $\wedge q' = 120° 59'$ ($121\frac{1}{2}°$), $\wedge f = 92° 26'$ (96°).

Twins: tw. pl. ⊥ *k*, geniculated; also as trillings (f. 2). Crystals small and indistinct; usually grouped in verruciform or reniform shapes. Faces *k* brilliant; *f* somewhat less so; *o* smooth but rounded; *m* striated parallel edge *m/m*. Also in rounded forms and compact massive.

1.



2.



No cleavage observed. Fracture uneven to flat conchoidal. Somewhat brittle. H. = 2·5. G. = 6·085–6·111. Luster metallic. Color steel-gray, on a fresh fracture, with a tinge of red turning to violet. Streak grayish black, shining.

**Comp.**—A sulpho-salt containing silver and the rare element germanium, first discovered in this species, $3Ag_2S.GeS_2$ = Sulphur 18·2, germanium 8·3, silver 73·5 = 100.

**Anal.**—Winkler, l. c.

S 17·13 Ge 6·93 Ag 74·72 Fe 0·66 Zn 0·22 = 99·66

On the chemical properties of germanium see Winkler, J. pr. Ch., **34**, 177, 1886; **36**, 177, 1887. This new element has also been identified in euxenite.

**Pyr.**—In the closed tube gives a brilliant black sublimate; in the open tube fumes of sulphur dioxide. On charcoal fuses to a bead, giving near the assay a faint white sublimate; after long blowing an orange-yellow sublimate and a silver globule.

**Obs.**—Found at the Himmelsfürst mine, Freiberg, associated with siderite, marcasite abundant, also sphalerite, pyrite, galena, further argentite, pyrargyrite, polybasite, stephanite; implanted sometimes on argentite and again on marcasite or siderite.

**Ref.**—[1] L. c., the measurements only approximate; the symbols of some of the planes are doubtful because measured and calculated angles vary widely; perhaps *v* should be 454, for which we have $454 \wedge \bar{4}54 = 49° 35'$.

1. 2. 3.

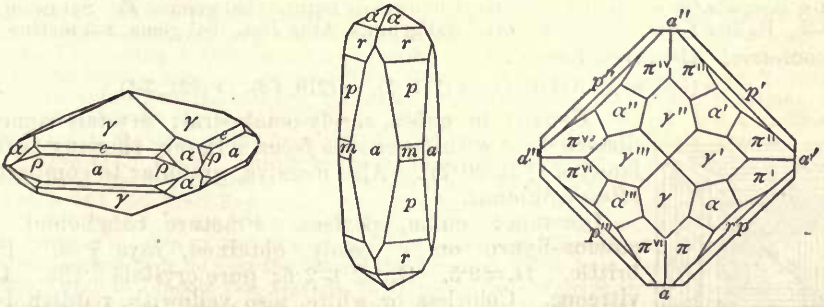

Fig. 1, El Doktor, Mexico, Websky[3]. 2, Moschellandsberg, Websky[3]. 3, Moschellandsberg, after Schrauf[1].

Twins: tw. pl. $e$, contact- and penetration-twins. Crystals sometimes tabular ‖ $c$; also pyramidal; often highly complex.

Cleavage: *a* rather distinct; also *r*. Fracture conchoidal. Sectile. H. = 1–2. G. = 6·482 Haid. Luster adamantine. Color white, yellowish gray, or ash-gray, also grayish, and yellowish white, brown. Streak pale yellowish white. Translucent—subtranslucent. Optically +. Double refraction strong. Indices·

$$\omega_r = 1·96 \qquad \epsilon_r = 2·60 \text{ Senarmont}^6$$

**Comp.**—Mercurous chloride, $Hg_2Cl_2$ = Chlorine 15·1, mercury 84·9 = 100.

**Pyr., etc.**—In the closed tube volatilizes without fusion, condensing in the cold part of the tube as a white sublimate; with soda gives a sublimate of metallic mercury. B.B. on charcoal volatilizes, coating the coal white. Insoluble in water, but dissolved by aqua regia; blackens when treated with alkalies.

**Obs.**—At Moschellandsberg in the Palatinate, coating the cavities of a ferruginous gangue, associated with cinnabar—crystals often large and well-defined; also at the quicksilver mines of Idria in Carniola; Almaden in Spain; Horzowitz in Bohemia; with cinnaber at Mt. Avala near Belgrade in Servia[5]. From El Doktor near Zimapan, Queretaro, Mexico[3].

Calomel is an old term of uncertain origin and meaning, perhaps from καλός, *beautiful*, and μελι, *honey*, the taste being sweet, and the compound the *Mercurius dulcis* of early chemistry; or from καλός and μέλας, *black*.

**Ref.**—[1] Schrauf, Atlas, Tf. XL, 1872; cf. earlier Brooke, Ann. Phil., **6**, 285, 1823; Sbs. artif. cryst., Ber. Ak. Wien, **9**, 394, 1852; Hbg., Abh. Senck. Ges., **1**, 24, 1854–5. [2] See Schrauf, l. c. [3] Websky, El Doktor, Mexico, Ber. Ak. Berlin, 461, 1877; also $\psi_3$ (3·1·11), $\rho_1$ (5·3·11), and $\rho_2$ (419) doubtful. [4] Traube, Mt. Avala, Belgrade, Zs. Kr., **14**, 571, 1888. [5] Vrba, Mt. Avala, ib., **15**, 455, 1885. [6] Quoted by Dx., Propr. Opt., **1**, 40, 1857.

MERCURIC CHLORIDE.—The occurrence of native corrosive sublimate ($HgCl_2$) is reported by Besnou near Iquique, in the desert of Atacama; the determination, however, was based only on some qualitative trials. Assoc. Franc. Adv. Sc., 533, 1878. The artificial salt is orthorhombic, cf. Rg., Kr. Ch., 257, 1881.

**165. NANTOKITE.** Nantoquita *Sieveking, Domeyko*, 2d App., Min. Chili, 51, 1867; 3d App., 22, 1871. Nantokit *Breith.*, B. H. Ztg., **27**, 3, 1868; Jb. Min., 814, 1872.

Isometric. Granular, massive, not in distinct crystals; artificial crystals tetrahedral.

Cleavage: cubic. Fracture conchoidal. H. = 2–2·5. G. = 3·930. Luster adamantine. Colorless to white or grayish. Transparent to translucent.

**Comp.**—Cuprous chloride, $Cu_2Cl_2$ = Chlorine 35·9, copper 64·1 = 100.

An analysis by Sieveking (l. c.) gave: Cl 35·52, Cu 64·17 = 99·69.

**Pyr.**—B.B. on charcoal fuses, coloring the flame intensely azure-blue; a globule of copper finally remains. Easily soluble in hydrochloric and nitric acids, also in ammonia. Gives off chlorine when struck with a hammer. Oxidizes readily on exposure to the air.

**Obs.**—Occurs with cuprite, native copper, and hematite, also chalcocite and other copper minerals at the mine Carmen Bajo, near Nantoko, Chili. Atacamite is sometimes formed by the oxidation of nantokite.

---

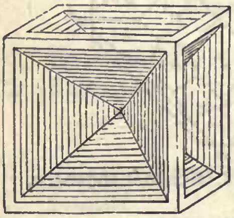
1

## Halite Group. RCl, etc.

**166. HALITE.** COMMON OR ROCK SALT. Muriate of Soda, Sodium Chloride. Kochsalz, Steinsalz, Bergsalz *Germ.* Soude muriatée, Chlorure de sodium, Sal gemme *Fr.* Sal mare *Beud.*, Tr., 1832 Halites *Glock.*, Syn., 290, 1847. Sal gemma, Alite *Ital.* Sal gema, Sal marina, *Span.*

Isometric. Observed forms[1]:

*a* (100, *i-i*), *d* (110, *i*), *o* (111, 1), *e* (210, *i*-2), *s* (321, 3-$\frac{3}{2}$).



Usually in cubes, rarely octahedral; crystals sometimes distorted, or with cavernous faces. Rarely showing twinning lamellæ (∥ 20·20·7)[2]. Also massive, granular to compact; less often columnar.

Cleavage: cubic, perfect. Fracture conchoidal. Percussion-figure on *a* easily obtained, rays ∥ *d*. Rather brittle. H.=2·5. G.=2·1–2·6; pure crystals 2·135. Luster vitreous. Colorless or white, also yellowish, reddish, bluish, purplish. Transparent to translucent. Soluble; taste saline. Refractive index 1·5442 Na., Langley[3]. Highly diathermanous. Sometimes exhibits anomalous double refraction.

**Comp.**—Sodium chloride, NaCl = Chlorine 60·6, sodium 39·4 = 100. Commonly mixed with calcium sulphate, calcium chloride, magnesium chloride, and sometimes magnesium sulphate, which render it liable to deliquesce.

For analyses quoted and references to others, see 5th Ed., p. 112; also under sylvite for Scacchi's observations on Vesuvian chlorides with KCl (natrikalite *Adam*, Tabl. Min., 69, 1869).

S. W. Johnson attributes the bluish or indigo color of some varieties from Stassfurt to sodium subchloride, Ochsenius to the presence of sulphur; this color disappears on heating. Wittjen & Precht (Ber. Chem. Ges., **16**, 1454, 1883) regard the color as an optical effect due to the presence of thin cavities having parallel surfaces with gas inclusions; they find the color distributed in lines mostly ‖ *o*, seldom ‖ *a*.

**Pyr., etc.**—In the closed tube fuses, often with decrepitation; when fused on the platinum wire colors the flame deep yellow. Added to a salt of phosphorus bead which has been saturated with oxide of copper, it colors the flame a deep azure-blue. Dissolves readily in three parts of water.

**Obs.**—Common salt occurs in extensive but irregular beds in rocks of various ages, associated with gypsum, polyhalite, anhydrite, carnallite, clay, sandstone, and calcite; also in solution forming salt springs; similarly in the water of the ocean and salt seas.

In Europe and England occurs in the Triassic, associated with red marl or sandstone, but not confined to these rocks. At Durham, Northumberland, and Leicestershire, England, salt springs rise from the Carboniferous series; in the Alps, some salt works are supplied from Oolitic rocks; the famous mines of Cardona in Spain and Wieliczka in Poland are referred, the former to the Green Sand formation, and the latter to Tertiary rocks. Salt springs also occur in volcanic regions. In the United States the brines of New York come from Upper Silurian strata; those of Ohio, Pennsylvania, and Virginia, mostly from Devonian and Subcarboniferous beds; those of Michigan, mainly from the Subcarboniferous and Carboniferous; while in Louisiana, at Petit Anse, there is a thick bed of large extent of pure salt in the Post-tertiary or more recent deposits of the coast. Salt also occurs as an essential part of the efflorescences over the dry prairies and shallow ponds or lakes of the Rocky mountains, California, Atacama, etc.; and in most desert or semi-desert regions there are numerous salt lakes.

The principal mines of Europe are at Wieliczka, in Poland; at Hall, in Tyrol; Stassfurt, near Magdeburg; and along the range through Reichenthal in Bavaria, Hallein in Salzburg, Hallstadt, Ischl, and Ebensee, in Upper Austria, and Aussee in Styria; in Hungary, at Marmoros and elsewhere; in Transylvania; Wallachia, Galicia, and Upper Silesia; Vic and Dieuze in France; Valley of Cardona and elsewhere in Spain, forming hills 300 to 400 feet high; Bex in Switzerland; and Northwich in Cheshire, England. At Cheshire it occurs in a basin-shaped deposit, and is arranged in spheroidal masses, from 5 to 8 feet in diameter, which are composed of concentric coats, and present polygonal figures. It is but little contaminated with impurities, and is prepared for use by merely crushing it between iron rollers. At the Austrian mines, where it contains much clay, the salt is dissolved in large chambers, and the clay thus precipitated. After a time the water, saturated with the salt, is conveyed by aqueducts to evaporating houses, and the chambers, after being cleared out, are again filled.

Salt also occurs, forming hills and covering extended plains, near Lake Urumia, the Caspian Lake, etc. In Algeria; in Abyssinia. In India in enormous deposits in the Salt Range of the Punjab; thus at the Mayo mines there are five great beds having an aggregate thickness of 275 feet alternating with another of 275 feet of *Kallar* or impure salt. Also in the Kohát district immense beds, in one place exceeding 1000 feet in thickness; at Mandi in the northwestern Himalayas; also at the salt lakes of Rájputána, and as an important part of a saline efflorescence (*Reh*) in alluvial deposits at various points (Mallet). In China and Asiatic Russia; in South America, in Peru, and at Zipaquera and Nemocon, the former a large mine long explored in the Cordilleras of U. S. of Colombia; clear salt is obtained from the Cerro de Sal, San Domingo. Occasionally formed at the eruptions of Vesuvius, as in 1855, when it was found in cubes, incrustations, and stalactites.

In the United States, salt has been found in large amount in central and western New York. Salt wells (see below) had long been worked in this region, but the presence of rock salt was first discovered by boring in 1878, and since then the industry has been rapidly developed. Salt is now known to exist over a large area from Ithaca at the head of Cayuga lake, Tompkins Co., and Canandaigua lake, Ontario Co., through Livingston Co., also Genesee, Wyoming, and Erie Cos. The salt is found in beds with an average thickness of 75 feet, but sometimes much thicker, and at varying depths from 1000 to 2000 feet and more; the depth increases southward with the dip of the strata. The rocks belong to the Salina period of the Upper Silurian. Salt has also been found near Cleveland, Ohio, associated with gypsum; there are here several beds, the widest 164 feet including shale, at depths from 2154 to 2475 feet. Also in Washington Co., West Virginia, in the Holston and Kanawha valleys; in Kansas, in beds from 10 to 100 feet in thickness at a depth of 700 feet or more in Ellsworth, Rice, Reno, Kingman, and Harper counties; the salt beds lie near the base of the Trias; at Petite Anse, Louisiana (see above); along the Rio Virgin in Lincoln Co., Nevada, in extensive beds of great purity; in Utah, near Nephi, Juab Co., and Salina, Sevier Co.; in Arizona, on the Rio Verde, with thenardite, etc., and mostly impure; the headwaters of Salt river, and Tonto basin, Gila Co.; in California, at Dos Palmas, San Diego Co. In Canada, salts occurs in Bruce, Huron, and Lampton Cos., Ontario, along the eastern shore of Lake Huron; it was first found at Goderich in 1866 at a depth of 964 feet, also at Clinton at a depth of 1180 feet, and later at other points.

Brine springs are very numerous in the Middle and Western States. These springs are worked at Salina, Syracuse, and elsewhere, N. Y.; in the Kanawha Valley, Va.; Muskingum, Ohio; Michigan, at Saginaw and elsewhere; in Kentucky and Tennessee; also at Goderich, Ontario, Canada. The salt water is obtained by boring, and raised by means of machinery, and thence conveyed by troughs to the boilers, where it is evaporated by artificial heat; or to basins for evaporation by exposure to the heat of the sun.

Composition of Syracuse brines, according to analyses by Dr. C. A. Goessmann (private communication):

| | I. | II. | III. | IV. |
|---|---|---|---|---|
| NaCl | 16·7503 | 15·5317 | 18·2465 | 13·3767 |
| $CaSO_4$ | 0·5673 | 0·5772 | 0·5117 | 0·5234 |
| $CaCl_2$ | 0·1594 | 0·1533 | 0·1984 | 0·1037 |
| $MgCl_2$ | 0·1464 | 0·1444 | 0·1784 | 0·1336 |
| $MgBr_2$ | 0·0022 | 0·0024 | 0·0025 | 0·0017 |
| KCl | 0·0110 | 0·0109 | 0·0119 | 0·0086 |
| $FeCO_3$ | 0·0034 | 0·0044 | 0·0036 | 0·0015 |
| $H_2O$ | 82·3600 | 83·5757 | 80·8470 | 85·8508 |
| | 100 | 100 | 100 | 100 |

No. I has G. = 1·1300 at 16° Baumé and 20° C. No. II has G. = 1·1225 at 15° Baumé and 21° C. The Saginaw brines, Michigan, afford about 19·250 of salt.

Vast lakes of salt water exist in many parts of the world. Lake Timpanogos in the Rocky mountains, 4,200 feet above the level of the sea, now called the Great Salt Lake, is 2,000 square miles in area L. Gale found in this water 20·196 per cent. of sodium chloride (Stansb. Exped., cited in Am. J. Sc., **17**, 129, 1854). The Dead and Caspian seas are salt, and the waters of the former contain 20 to 26 parts of solid matter in 100 parts. Gmelin, who analyzed a portion of these waters of specific gravity 1·212, found them to contain $CaCl_2$ 3·336, $MgCl_2$ 12·167, NaCl 7·039, $CaSO_4$ 0·052, $MgBr_2$ 0·443, KCl 1·086, $AlCl_3$ 0·144, $NH_4Cl$ 0·007, $MnCl_2$ 0·161, = 24·435, with 75·565 water = 100. This result is given as corrected by Marchand.

An analysis of the water of Great Salt Lake (1869) by O. D. Allen (U. S. G. Surv. 40th Par. **2**, 433) gave:

| NaCl | $MgCl_2$ | $Na_2SO_4$ | $K_2SO_4$ | $CaSO_4$ | Cl |
|---|---|---|---|---|---|
| 79·11 | 9·75 | 6·22 | 3·58 | 0·57 | 0·57$^a$ = 100 |

$^a$ Excess.

Salt is obtained on a large scale commercially, in the U. S., by the evaporation of the waters of the Great Salt Lake, and in California from the sea-water in San Francisco Bay.

**Alt.**—Anhydrite, gypsum, polyhalite, occur as pseudomorphs after this species; also celestite, dolomite, quartz, hematite, pyrite; the removal of the salt cubes by their solution leaves a cavity which any mineral may then occupy. The hopper-shaped crystals often leave an impression of their form in clays.

MARTINSITE *Karsten*, J. pr. Ch., **36**, 127, 1845. Halite containing 9 p. c. $MgSO_4$; from Stassfurt.

HUANTAJAYITE *Raimondi*, Domeyko, Min. Chili, 5th Append., 1876; Min. Pérou, p. 64, 1878. An argentiferous variety of halite, if homogeneous. Described as occurring in cubes, also in incrustations made up of minute cubic crystals, also fibrous. H. = 2. Color white, not altered by exposure. Transparent. Fragile, not sectile like cerargyrite. Composition: 20NaCl + AgCl; an analysis ($\frac{3}{8}$) gave: NaCl 89, AgCl 11 = 100. B.B. decrepitates and fuses easily: on charcoal yields silver with soda. Occurs in a calcareous gangue with cerargyrite, embolite, etc., at the mine of San Simon, Huantajaya, Tarapaca, Chili. Called *lechedor* by the miners.

HYDROHALITE *A lam*, Tabl. Min., p. 69, 1869. A hydrous sodium chloride described by Mitscherlich; see Hausm. Handb., p. 1459, 1847.

**167. SYLVITE.** Muriate of Potash (fr. Vesuvius) *Smithson*, Ann. Phil., **6**, 258, 1823. Chloride of Potassium, Potassium chloride. Chlorkalium, *Germ.* Sylvine *Beud.*, Tr., **2**, 511, 1832. Hoevelit *H. Girard*, Jahrb. Min., 568, 1863. Leopoldit *E. Reichardt*, Jahrb. Min. 331, 1866 Schätzellit and Hövellit (fr. Stassfurt), B. H. Ztg., **24**, 276, Ann. Ch. Phys., **5**, 318, 324.

Isometric. Observed forms[1]:

*a* (100, *i-i*) *q* (540, *i*-$\frac{5}{4}$) *τ* (722, $\frac{7}{2}$-$\frac{7}{2}$) *β* (322, $\frac{3}{2}$-$\frac{3}{2}$) *y* (845, $\frac{8}{5}$-2).
*o* (111, 1) *ξ* (711, 7-7) *n* (211, 2-2) *t* (421, 4-2)

Brauns has obtained by etching faces of 931 (9-3 r) as a trapezohedal hemihedral form[2].

Habit cubic; *a*, also *a* with *o*, most common. Also in granular crystalline masses, rarely columnar; compact.

Cleavage: cubic, perfect. Fracture uneven. Brittle. H. = 2. G. = 1·97-1·99 Prietze, l. c. Luster vitreous. Colorless, white, bluish or yellowish red from inclusions. Transparent when pure. Refractive index[3], $n_y$ = 1·49031 Na. Soluble; taste, much like that of common salt, but somewhat bitter. Sometimes exhibits anomalous double refraction. Highly diathermanous[4].

**Comp.**—Potassium chloride, KCl = Chlorine 47·6, potassium 52·4 = 100. Sometimes contains also sodium chloride.

A. Müller (Vh. Ges. Basel, 113, 1854) found a Vesuvian salt pure with only a trace of sodium. Scacchi (Contrib. Min. Vesuv., II, 23) gives analyses of fifteen varieties with K : Na = 100 : 6·2. 10 : 17·5, etc., up to 10 : 94·8; some of the varieties contained also the alkaline sulphates, with (K.Na)Cl : (K,Na)$_2$SO$_4$ = 100 : 0·43. 100 : 6·45. 100 : 4·50, etc. Prietze, quoted by Huyssen (Zs. G. Ges., **20**, 461, 1868, and Jb. Min., 484, 1868) found in some of the Stassfurt sylvite 12 to 13 p. c. NaCl and 0·5 SO$_3$, but other analyses of material carefully separated from halite showed the pure KCl.

**Pyr., etc.**—B.B. in the platinum loop fuses, and gives a violet color to the outer flame. Added to a salt of phosphorus bead, which has been previously saturated with oxide of copper, colors the O.F. deep azure-blue. Dissolves in water, 100 parts taking up 34·5 at 18·75° C. Heated with sulphuric acid gives off hydrochloric acid gas.

**Obs.**—Occurs at Vesuvius, about the fumaroles of the volcano. Also at Stassfurt, in the carnallite beds of the salt formation; at Leopoldshall (*leopoldite*); at Kalusz in Galicia, where with the accompanying picromerite it has been derived (Tschermak, l. c.) from the alteration of carnallite.

The compound is the *Sal digestivus Sylvii* of early chemistry, whence Beudant's name for the species.

**Ref.**—[1] Tschermak, Kalusz, Anz. Ak. Wien, p. 24, 1868; Ber. Ak. Wien, **63** (1), 308, 1871. [2] Jb. Min., **1**, 224, 1886; also, **1**, 121, 1889. [3] Stefan, Ber. Ak. Wien, **63** (2), 241, 1871. [4] Magnus, Pogg., **134**, 302, 1868.

For experiments in *elasticity*, see Voigt, Nachr. Ges. Gött., 330, 1888; on *hardness*, Exner, Härte Kryst., p. 37, 1873.

**168. SAL-AMMONIAC.** Natürliches Salmiak (fr. Bucharia) *J. G. Model*, Versuch über ein nat. Salmiak, Leipzig, 1758. Muriate of Ammonia; Chloride of Ammonium. Salmiak *Germ.* Ammoniaque muriatée *Fr.* Salmiac *Beud.*, Tr., 1832. Clorammonio *Ital.*

Isometric. Observed planes[1]:

*a* (100, *i-i*) *d* (110, *i*) *o* (111, 1) *n* (211, 2-2) *s* (321, 3-$\frac{3}{2}$)

Artificial crystals show trapezohedral hemihedrism in the form 875 ($\frac{8}{5}$-$\frac{8}{7}$ r) Tschermak[3]. Naumann[2] has described forms with 311 developed with tetragonal symmetry, and others with 411, 310, having rhombohedral symmetry.

Twins: tw. pl. *o*. Also stalactitic, and in globular masses; in crusts, or as an efflorescence.

Cleavage: *o* imperfect. Fracture conchoidal. Rather brittle. H. = 1·5–2. G. = 1·528. Luster vitreous. Color white, yellowish, grayish. Transparent to translucent. Index $n_y$ = 1·6422 Grailich.

**Comp.**—Ammonium chloride, $NH_4Cl$ = Chlorine 66·3, ammonium 33·7 = 100. Chloride of iron is sometimes present giving a yellow color.

**Pyr., etc.**—Sublimes in the closed tube without fusion. Pulverized with calcium hydrate, or heated with a solution of caustic alkali, gives off pungent ammoniacal vapors. Soluble in three times its weight of water.

**Obs.**—Occurs about volcanoes, as at Etna, the island of Vulcano, Vesuvius, Stromboli, Sandwich Islands, and near Hecla after the eruption of 1845, as observed by Bunsen. Observed after the eruption of Vesuvius in 1855, in rhombic dodecahedrons with cavernous faces, and again in the lava of 1868 (Scc., l. c.) in more complex crystals, in part twins. It occurs usually where the lava has spread over soil and vegetation. Also found in small quantities in the vicinity of ignited coal seams, as at St. Etienne in France, and also at Newcastle, and in Scotland; crystallized near Duttweiler in Prussia, where a coal seam has been burning for more than a hundred years. It occurs also in Bucharia; at Kilauea in Hawaii, a variety which contains iron, and becomes rusty yellow on exposure; in guano from the Chincha Islands.

The *ἅλς ἀμμωνιακός*, sal-ammoniac of Dioscorides, Celsius, and Pliny, is proved by Beckmann (Hist. of Inventions, **4**, 360) to be common rock salt, dug in Egypt, near the oracle of Ammon. The name was afterward transferred to this compound, when subsequently manufactured in Egypt. Sal-ammoniac is supposed to have been included by the ancients, with one or two other species, under the name of *nitrum*, which, according to Pliny, gave the test of ammonia when mingled with quicklime.

**Ref.**—[1] Scacchi. Rend. Acc. Napoli, Oct., 1872. [2] Naumann, J. pr. Ch., **50**, 11, 310, 1850. Min. Mitth., **4**, 531, 1881.

**169. CERARGYRITE.** Argentum cornu pellucido simile (fr. Marienberg), *Germ.* Hornfarbs-Silber, *Gesner*, Foss., 63, 1565. Argentum rude jecoris colore, lucem corneam habens (fr. Freiberg, etc.) *G. Fabricius*, De Rebus Met., 1566. Glaserz, dursichtig wie ein Horn in einer Lantern, *Matthesius*, Sarept., 1585. Horn-Silfver, Minera argenti cornea, A. sulphure et arsenico mineralisatum, *Wall.*, 310. 1747. Argento acido salis mineralisatum, Hornerz, *Cronst.*, 159, 1758. Buttermilcherz (first mentioned early in 17th century). Kerargyre *Beud.*, Tr., **2**, 501, 1832. Kerat *Haid.*, Handb., 506, 1845. Argyroceratite *Glock.*, Syn., 249, 1847. Chlorargyrit *Weisbach*, Synops. Min., 37, 1875. Kerargyrite.

Silberhornerz, Silberkerat, Hornsilber, Chlorsilber, *Germ.* Chlorsilfver, Silfverhornmalm *Swed.* Horn Silver, Corneous Silver. Argent muriaté, Argent corné, Chlorure d'argent *Fr.* Cherargirio, Argento cornea *Ital.* Plata cornea *Span.*

Isometric. Observed forms[1]:

*a* (100, *i-i*) *d* (110, *i*) *o* (111, 1) *p* (221, 2) *n* (211, 2-2)

Twins: tw. pl. *o*. Habit cubic. Usually massive and resembling wax; sometimes columnar; often in crusts.

Cleavage none. Fracture somewhat conchoidal. Highly sectile. H. = 1–1·5. G. = 5·552. Luster resinous to adamantine. Color pearl-gray, grayish green, whitish to colorless, rarely violet-blue; on exposure to the light turns violet-brown. Transparent to translucent. Index[2], $n_y$ = 2·0611 Na.

**Comp.**—Silver chloride = Chlorine 24·7, silver 75·3 = 100.

Some varieties contain mercury; Domeyko (Min. Chili, 3d Ed., p. 416, 1879) describes one from the La Julia mine, of the Cerro de Caracoles, Atacama, which yielded: Cl 22·64, Ag 66·68, Hg 2·20 = 91·52, with impurities and loss 8·48. Moesta gives 1·31 p. c. mercury for the cerargyrite of Los Bordos, Copiapo. See also huantajayite under halite (p. 156), and the species which follow.

**Pyr., etc.**—In the closed tube fuses without decomposition. B.B. on charcoal gives a globule of metallic silver. Added to a bead of salt of phosphorus, previously saturated with oxide of copper and heated in O.F., imparts an intense azure-blue to the flame. A fragment placed on a strip of zinc, and moistened with a drop of water, swells up, turns black, and finally is entirely reduced to metallic silver, which shows the metallic luster on being pressed with the point of a knife. Insoluble in nitric acid, but soluble in ammonia.

**Obs.**—Occurs in veins of clay slate, accompanying other ores of silver, and usually only in the higher parts of these veins. It has also been observed with ocherous varieties of brown iron ore; also with several copper ores, calcite, barite, etc.; upon stibiconite.

The largest masses, and particularly those of a green color, are brought from Peru, Chili, and Mexico, where it occurs with native silver. In Chili, at some mines, it is a much less common ore than embolite; often contains, intimately mixed with it, native silver in very minute grains; it occurs at Tres Puntas, Atacama, Chañarcillo near Copiapo, and elsewhere in Chili. Also in Nicaragua near Ocotal; in Dept. of Gracias, Honduras. It was formerly obtained in the mining districts of Johanngeorgenstadt and Freiberg, but is now rare; a mass weighing six and three-quarter pounds, from this region, is in the Zwinger collection at Dresden. It also occurs in the Altai, at the mines of Zmeinogorsk and Krukovskoi; at Kongsberg in Norway; in Alsace; rarely in Cornwall, and at Huelgoet in Brittany. In thin incrustations on stibiconite from Sonora, Mexico.

In the U. S., in Colorado, near Leadville, Lake Co.; near Breckenridge, Summit Co., and elsewhere. In Nevada, about Austin, Lander Co., abundant; at mines of Comstock lode. In Arizona, in the Willow Springs distr., veins of El Dorado cañon, in San Francisco distr. In Idaho, at the Poorman mine, in crystals, some half an inch across, mostly cubes and cubo-octahedrons, but occasionally with other planes, and in twins consisting of two interpenetrating cubes, the angles of one projecting from the faces of the other; also at various mines in Custer Co., Alturas Co., and at the Horn Silver and other mines, Tara Creek. In Utah, in Beaver, Summit and Salt Lake counties.

At Andreasberg in the Harz, an earthy variety is met with, called by the Germans Buttermilk ore (*Buttermilcherz, thonige Hornsilber*), which, according to Klaproth (Beitr., **1**, 137, 1795), contains: Silver 24·64, chlorine 8·28, alumina (Cu *tr.*) 67·08. Funckens describes it as "weiss und dünn wie eine Buttermilch" (Lenz Min., **2**, 101, 1794).

Named from *κέρας*, *horn*, and *ἄργυρος*, *silver*—*Ceratargyrite*, the proper derivative, being contracted to *Cerargyrite*. The Greek *k* becomes *c*, as in other cases.

**Ref.**—[1] Cf. Gdt.. Index, **1**, p. 437, 1886. [2] Wernicke, Pogg., **142**, 560, 1871.

Bordosite *Bertrand*, Ann. Mines, **1**, p. 412, 1872. A mineral substance, color yellow to red, occurring with amalgam and resulting from its decomposition. It becomes dark rapidly on exposure to the air. Analysis: AgCl 31·23, HgCl 45 53, HgO 22·70 = 99·46 Bertrand regards the HgO as adventitious, and proposes for it the name *hydrargyrite;* deducting this there remain: AgCl 40·69, and HgCl 59·31 = 100, or AgCl + HgCl, to which he gives the name of *bordosite*. Both species are very uncertain. Locality Los Bordos, Chili.

**170. EMBOLITE.** Chlorobromure d'argent *Domeyko*, Ann. Mines, **6**, 153, 1844; Berthier, ib., **2**, 540, 1842. Plata cornea verde *Domeyko*, Min., 202, 1845. Embolit *Breith.*, Pogg., **77**, 134, 1849. Chlorobromide of Silver. Chlorbromsilber. Megabromite, Microbromit, *Breith.*, B. H. Ztg., **18**, 449, 1859.

Isometric Observed forms:

*a* (100, *i-i*) *d* (110, *i*) *o* (111, 1) *e* (210, *i*-2)

Usually massive; sometimes stalactitic or concretionary on surface.

Cleavage none. Fracture uneven. Sectile. H. = 1–1·5. G. = 5·31–5·43 Domeyko; 5·53 Yorke; 5·79–5·81 Breith. Luster resinous, somewhat adamantine. Color grayish green and asparagus-green to yellowish green; yellow, often dark and becoming darker on exposure. Transparent to translucent.

**Comp.**—Ag(Cl,Br), the ratio of the chlorine to the bromine varying indefinitely, the yellowish varieties and those of deeper green colors containing the largest proportion of bromine.

**Anal.**—1, W. von Beck, Jb. Min., 165, 1876. 2, Munro, Ch. News, **53**, 99, 1886. 3, C. Wood quoted by Welch, ib., **54**, 94, 162, 1886.

| | Br | Cl | Ag |
|---|---|---|---|
| 1. Orenburg, *cryst.* | 28·44 | 8·20 | 63·36 = 100 |
| 2. St. Arnaud, Victoria | 25·84 | 9·70 | 64·45 = 99·99 |
| 3. " " | 24·16 | 10·73 | 65·14 = 100·03 |

For other analyses, see 5th Ed., p. 116, these show variations from AgCl = 81·4 and AgBr 18·6 to AgCl 51 and AgBr 49. Cf. Welch, l. c., for a discussion of the various analyses published.

The *megabromite* and *microbromite* of Breithaupt are varieties of embolite based on the proportion of bromide to chloride; and are even indistinct as varieties, these extremes being connected by indefinite shadings.

**Obs.**—Abundant in Chili, constituting the principal silver ore of the mines of Chañarcillo, and found also at Agua-Amarga, Tres-Puntas, Rosilla, and at all the new openings in the province of Copiapo; found also at Eulalia in Chihuahua, Mexico; at the mine of Coloal in Gracias, Honduras. At St. Arnaud, Victoria; in New South Wales, at Sunny Corner, Bathurst, and in the Silverton mines.

Named from *ἐμβόλιον, an intermediate*, because between the chloride and bromide of silver.

**171. BROMYRITE.** Bromure d'Argent, Plata verde *Mex.* (fr. Mexico and Huelgoet), *Berth.*, Ann. Mines, **19**, 734, 742, 1841, **2**, 526, 1842. Bromide of Silver; Bromic Silver. Bromsilber *Germ.* Bromit *Haid.*, Handb., 506, 1845. Bromyrite *Dana*, Min., 93, 1854. Bromargyrit *Rg.*, Min. Ch., 196, 1860. Plata cornea amarilla melada *Domeyko*, Min., 214, 1860.

Isometric. Observed forms:

*a* (100, *i-i*) *d* (110, *i*) *o* (111, 1)

Crystals rare. Usually in small concretions.

Cleavage none. Fracture uneven. Sectile. H. = 2–3. G. = 5·8–6. Luster resinous to adamantine. Color, when pure, bright yellow to amber-yellow; slightly greenish; often grass- or olive-green externally; little altered on exposure. Transparent to translucent. Index, $n_y$ = 2·2533 Na, Wernicke.

**Comp.**—Silver bromide, AgBr = Bromine 42·6, silver 57·4 = 100.

**Pyr., etc.**—In the closed tube and with metallic zinc reacts like cerargyrite. B.B. on charcoal emits pungent bromine vapors and yields a globule of metallic silver. Fused with potassium bisulphate in a matrass gives off yellowish brown vapors of bromine. Insoluble in nitric acid. Difficultly soluble in ammonia.

**Obs.**—With other silver ores in the district of Plateros, Mexico, and at the mine of San Onofre, seventeen leagues from Zacatecas, associated with cerargyrite and cerussite; also in crystals at Chañarcillo, Chili, with cerargyrite, sometimes embedded in calcite; also at Huelgoet in Brittany, with cerargyrite.

**172. IODOBROMITE.** Jodobromit *A. von Lasaulx*, Jb. Min., 619, 1878. Jodbromchlorsilber *Germ.*

Isometric. In octahedrons with cubic planes.

Cleavage: *o* indistinct. Sectile. Soft. G. = 5·713. Luster resinous. Color sulphur-yellow, sometimes greenish.

**Comp.**—$2AgCl.2AgBr.AgI$ = Chlorine 7·9, bromine 17·8, iodine 14·1, silver 60·2 = 100.

**Anal.**—Lasaulx, l. c.

Cl 7·09 Br 17 30 I 15·05 Ag 59·96 = 99·40

**Pyr., etc.**—B.B. on charcoal gives off bromine vapors and leaves a silver globule.

**Obs.**—Found in small cavities in ferruginous quartz at the "Schöne Aussicht" mine, near Dernbach, Nassau, associated with beudantite, carminite, and iodyrite.

---

**173. IODYRITE.** Iodure d'Argent *Vauquelin*, Ann. Ch. Phys., **29**, 99, 1825; *Domeyko*, Ann. Mines, **6**, 158, 1844. Plata cornea amarilla clara *Domeyko*, Min., 205, 1845. Iodic Silver. Iodsilber *Germ.* Iodit *Haid.*, Handb., 506, 1845. Iodyrite *Dana*, Min., 95, 1854. Iodargyrit *Rg.*, Min. Ch., 197, 1860. Iodsilber, Jodsilber *Germ.* Argent ioduré *Fr.*

Hexagonal; hemimorphic. Axis $\dot{c} = 0·81960$; $0001 \wedge 10\bar{1}1 = 43° 25' 20''$ Zepharovich[1].

**Forms**[2]: *m* ($10\bar{1}0$, *I*) *e* ($30\bar{3}4$, $\frac{3}{4}$) as tw. pl. *g* ($30\bar{3}2$, $\frac{3}{2}$) *f* ($30\bar{3}1$, 3)
*c* (0001, *O*) *μ* ($10\bar{1}2$, $\frac{1}{2}$) *o* ($10\bar{1}1$, 1) *i* ($20\bar{2}1$, 2) *u* ($40\bar{4}1$, 4)

Also on artif. crystals[3]: *a* ($11\bar{2}0$, *i*-2); *ν* ($20\bar{2}3$, $\frac{2}{3}$)?, *e* ($30\bar{3}4$, $\frac{3}{4}$), *π* ($40\bar{4}5$, $\frac{4}{5}$)?; *β* ($9·9·\bar{18}·20$, $\frac{9}{10}$-2)?.

$c\mu = 25° 19'$ $ci = 62° 9'$ $cu = 75° 12'$ $ii' = 52° 28\frac{1}{2}'$
$ce = 35° 22'$ $cf = 70° 36'$ $oo' = 40° 12'$ $uu' = 57° 49'$
$cg = 54° 50'$

Iodyrite is homœomorphous with greenockite. An isometric form is also known,[4] into which the hexagonal form passes on increase of temperature, and conversely. The former change is accompanied by absorption of heat[5].

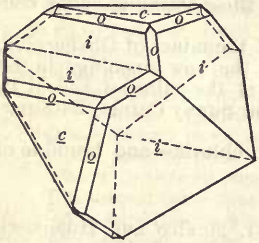
Natural crystals in hexagonal prisms; rarely twins[6] with tw. pl. *e*. Also massive, and in thin plates with a lamellar structure.

Cleavage: *c* perfect. Sectile, plates flexible.

Soft. G. = 5·60–5·70; 5·707 Dmr.; 5·609 Rath. Luster resinous to adamantine. Color citron- and sulphur-yellow to yellowish green, sometimes brownish. Streak yellow. Translucent. Index, $n_y = 2·1816$ Na, Wernicke.

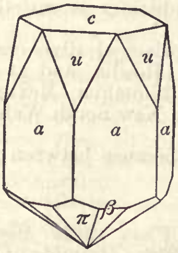
**Comp.**—Silver iodide, $AgI$ = Iodine 54, silver 46 = 100.

1.



New Mexico, Rath[6].

2.



Artif. cryst., Zeph[1].

**Pyr., etc.**—In the closed tube fuses and assumes a deep orange color, but resumes its yellow color on cooling. B.B. on charcoal gives fumes of iodine and a globule of metallic silver. With zinc reacts like cerargyrite and bromyrite. Fused with potassium bisulphate in a matrass, yields violet vapors of iodine.

**Obs.**—Occurs in thin veins or seams in hornstone at Albarradon, near Mazapil, in Mexico; at Algodones, 12 leagues from Coquimbo; less abundantly at Delirio mines of Chañarcillo, Chili, where the crystals are sometimes half an inch broad; also at Guadalajara in Spain. At Dernbach, Nassau, with iodobromite. In Arizona at Cerro Colorado mine. In New Mexico, with vanadinite and descloizite at Lake Valley, Sierra Co.

**Ref.**—[1] Artif. cryst., Zs. Kr., **4**, 119, 1879; Dx. obtained $\dot{c} = 0·81438$, Ann. Ch. Phys., **40**, 85, 1854. [2] See Dx., l. c. TOCORNALITE *Domeyko*, 2d App. Min. Chili, 41, 1867. Plata iodurada mercurial. Granular massive. Color pale yellow, becoming darker on exposure. Streak yellow. An iodide of silver and mercury.

Analysis gave: Ag 33·80, Hg 3·90, I 41·77, siliceous residue 16·65 = 96·12. The loss is due to some water belonging with the residue, and probably some iodine. From the mines of Chañarcillo, Chili. Named after M. A. Tocornal, rector of the Santiago university.

Several minerals, chloro-iodides of silver and mercury but of variable composition, are mentioned by Domeyko, Min. Chili, 3d Ed., 431, 1879.

COCCINITE. Iodure de Mercure *Del Rio*, Ann. Mines, **5**, 324, 1829; *Beud.*, Tr., **2**, 515, 1832. Coccinit *Haid.*, Handb., 572, 1845. Mercure iodure *Fr.* Iodquecksilber *Germ.* Chlorselenquecksilber *del Castillo.*

In particles of a reddish brown color on selenide of mercury, adamantine in luster, at Casas Viejas, Mexico; and supposed by Del Rio to be an iodide of mercury. But Castillo says (Colegio de Min. Mexico, 1865) that specimens labeled by Del Rio contain no iodine, and appear to be largely chlorine and mercury, yet are not calomel. Castillo describes it from Zimapan and Culebras, both massive and in acute, acicular, rhombic pyramids, 2–6 mm. long; color fine red to yellow, and sometimes yellowish green, changing to greenish gray and dark green on exposure; transparent to translucent. In a closed tube affords a sublimate, white when cold, of $Hg_2Cl_2$, and leaves a residuum which is dull red while hot, orange-yellow when cold, and which B.B. turns aurora-red, and is dissipated with an odor like that of selenium.

ZIMAPANITE *Adam*, Tabl. Min., 70, 1869. A hypothetical vanadium chloride, credited to Del Rio.

BUSTAMENTITE *Adam*, Tabl. Min., 67, 1869. Hypothetical lead iodide, $PbI_2$, not known to occur in nature. The artificial compound is hexagonal, cf. Rg., Kr. Ch., 305, 1881.

ZINC IODIDE—ZINC BROMIDE.—Iodine and bromine are stated by Mentzel to occur along with a cadmiferous zinc in Silesia, and hence it is inferred that iodide and bromide of zinc exist in nature, though not yet distinguished. Ann. Mines, **5**, 324, 1829.

---

## **Fluorite Group.** $\overset{\text{II}}{R}(Cl,F)_2$. Isometric.

**174. HYDROPHILITE.** Hydrophilit *Hausm.*, Handb., 857, 1813. Chlorure de Calcium, *Beud.*, Tr., **2**, 512, 1832. Clorocalcite *Scacchi*, Rend. Acc. Sc. Napoli, Oct. 12, 1872; Contrib. Min. Vesuv., II, 37 (Mem. Acc. Sc. Napoli, Dec. 13, 1873). Chlorocalcite.

Isometric. In cubic crystals, sometimes with *o* and *d*. As a crystalline or mealy incrustation.

G. = 2·2 artif. Color white, sometimes stained violet. Transparent to translucent. Taste bitter. Deliquesces readily.

**Comp.**—Calcium chloride, $CaCl_2$ = Chlorine 64·0, calcium 36·0 = 100.

The *chlorocalcite* from Vesuvius contained also the chlorides of potassium, sodium, and manganese.

**Pyr., etc.**—B.B. fusible. Very soluble in water, attracting moisture from the air and rapidly deliquescing.

**Obs.**—Occurs at Luneburg in anhydrite and gypsum, and associated with halite (Hausm.). At Vesuvius in crystals (*chlorocalcite*) in bombs of the eruption of April, 1872.

At Guy's Cliffe, Warwickshire, as an impure slimy exudation on sandstone. Mixed with clay in the province of Tarapaca and elsewhere in Peru. From crevices between ejected blocks near the middle of a solfatara in the crater of Barren island, Bay of Bengal, chiefly as a red and orange deliquescent incrustation mixed with ferric oxide and basic aluminium sulphate (Mallet).

Named from ὕδωρ, *water*, and φίλος, *friend*, in allusion to its hygroscopic properties.

The hydrous calcium chloride ($CaCl_2 + 6H_2O$) is known in artificial crystals belonging to the hexagonal system, cf. Rg., Kr. Ch., 265, 1881.

**175. FLUORITE** or FLUOR SPAR. Fluores lapides gemmarum similis sed minus duri—qui ignis calore liquescunt [whence he derives the name]—Colores varii, jucundi, (1) rubri, (2) purpurei (vulgo amethysti), (3) candidi, (4) lutei, (5) cineracei, (6) subnigri, etc. [with mention also of its use as a flux in smelting], *Agric.*, Berm., 458, 1529; *Germ.* Flusse *id.*, Interpr., 464, 1546. 1.

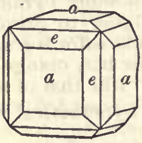
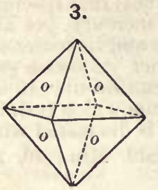
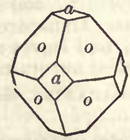
2.



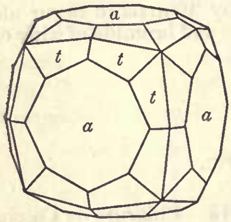
3.



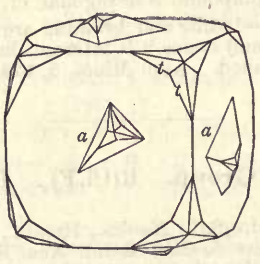
4.



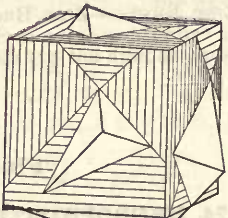
5.



6.



7.



Figs. 1–4, simple forms. 5. Freiberg. 6, 7, Alston Moor, England.

Twins: tw. pl. $o$, commonly penetration-twins (f. 6, 7). Habit cubic, often modified; less frequently octahedral or dodecahedral; forms $f$, $e$ (fluoroids) common; also the vicinal form $\zeta$, producing striations on $a$ (f. 8); hexoctahedron $t$ also common. Cubic crystals sometimes grouped in parallel position, thus forming a pseudo-octahedron. Also massive; granular, coarse or fine; rarely columnar; compact.

Cleavage: $o$ perfect. Fracture flat-conchoidal; of compact kinds splintery. Brittle. H. = 4. G. = 3·01–3·25; 3·180–3·189 Kenngott, mean 3·183. Luster vitreous, sometimes splendent; usually glimmering in massive varieties. Color white, yellow, green, rose- and crimson-red, violet-blue, sky-blue, and brown: wine-yellow, greenish blue, violet-blue, most common; red, rare. Streak white. Transparent—subtranslucent. Sometimes presenting a bluish fluorescence. Phosphoresces when heated gently. Refractive index for Na: $n_y$ = 1·4339 Sarasin; $n_y$ = 1·4324 (gray), 1·4342 (black), Kohlrausch. The index diminishes slightly with increase of temperature. Etching, natural and artificial, develops depressions corresponding usually to faces of $m$ (311) or $f$ (310); also other forms. Exhibits a difference of electrical potential between the faces and angles of a cube, both under the action of heat (pyro-electric) and of light (photo-electric). Sometimes exhibits anomalous double refraction[12]. See also p. 1034.

Hussak finds that all fluorite shows double refraction with varying degrees of intensity, the crystals consisting of a series of lamellæ crossing one another and apparently parallel to the dodecahedral planes. Isotropic spots also occur, though rarely. The structure of the crystals is that of the orthorhombic system with the axis of least elasticity normal to a cubic face. The abnormal double refraction is probably to be regarded as secondary and due to internal tension; it does not disappear at a red heat.

**Comp.**—Calcium fluoride, $CaF_2$ = Fluorine 48·9, calcium 51·1=100. Chlorine is sometimes present in minute quantities.

**Var.**—1. *Ordinary;* (*a*) cleavable or crystallized, very various in colors; (*b*) fibrous to columnar, as the Derbyshire blue-john used for vases and other ornaments; (*c*) coarse to fine granular; (*d*) earthy, dull, and sometimes very soft. A soft earthy variety from Ratovka, Russia, of a lavender-blue color, is the *ratovkite* or *ratofkite*.

The finely colored fluors have been called, according to their colors, *false* ruby, topaz, emerald, amethyst, etc. The colors of the phosphorescent light are various, and are independent of the actual color; the kind affording a green color is the *chlorophane* (fr. χλωρος, *green*, and φαίνεσϑαι, *to appear*) or *pyro-emerald*.

Wyrouboff attributes the various colors to compounds of carbon and hydrogen, derived from a slight infusion of organic matters in the solvent waters; he found (Bull. Soc. Ch., **5**, 334, 1866) that the blue and violet colors changed to purple on heating, and supposes that two CH substances, a blue and a red, were present, the former more volatile, and therefore leaving the color reddish after partial heating.

Breithaupt obtained for fluorite: G. = 3·017, fr. Alston Moor, Cumberland, white; 3·170, Euba, blue; 3·176, ib., white; 3·171, fr. Siberia, blue; 3·183, ib., white; 3·166, fr. near Marienberg, green; 3·172, ib., blue; 3·169, fr. Bösenbrunn in Voigtland, green; 3·186, ib., blue, 3·188, ib., white; 3·185, fr. Cornwall, fluorescent; 3·188, fr. Switzerland, rose-red; 3·193, fr. near Freiberg, green; 3·255, fr. Mexico, emerald-green transparent oct.; 3·324–3·357, fr. Siberia, violet-blue. For Kenngott's observations on specific gravity see Ber. Ak. Wien, **10**, 1853.

2. *Antozonite* of Schönbein. Stinkfluss *Germ.* The dark violet-blue fluor of Wölsendorf, Bavaria, afforded Schrötter 0·02 p. c. of ozone, which Schönbein (J. pr. Ch., **83**, 95, 1861, **89**, 7, 1863) called *antozone*, whence his name for this variety. Its strong odor is said often to produce headache and vomiting in the miners. More recently antozone has been shown to have no real existence, and the odor of this variety has been attributed to free fluorine.

**Pyr., etc.**—In the closed tube decrepitates and phosphoresces. B.B. in the forceps and on charcoal fuses, coloring the flame red, to an enamel which reacts alkaline on test paper. With soda on platinum foil or charcoal fuses to a clear bead, becoming opaque on cooling; with an excess of soda on charcoal yields a residue of a difficultly fusible enamel, while most of the soda sinks into the coal; with gypsum fuses to a transparent bead, becoming opaque on cooling. Fused in an open tube with fused salt of phosphorus gives the reaction for fluorine. Treated with sulphuric acid gives fumes of hydrofluoric acid which etch glass.

**Obs.**—Sometimes in beds, but generally in veins, in gneiss, mica slate, clay slate, and also in limestones, both crystalline and uncrystalline, and sandstones. Often occurs as the gangue of metallic ores, especially of lead. In the North of England, it is the gangue of the lead veins which intersect the coal formation in Northumberland, Cumberland, Durham, and Yorkshire. In Derbyshire it is abundant, and also in Cornwall, where the veins intersect metamorphic rocks. The Cumberland and Derbyshire localities especially have afforded magnificent specimens. Common in the mining district of Saxony; fine near Kongsberg in Norway. In the dolomites of St. Gothard it occurs in pink octahedrons; at Münsterthal in Baden in flesh-red hexoctahedrons. Rarely in volcanic regions, as in colorless octahedrons in the Vesuvian lava; also in massive form with other fluorine compounds in ejected masses inclosed in the tufa of Fiano and at other points in the Campania.

In *Maine*, on Long Island, Blue Hill Bay, in veins. In *N. Hampshire*, at N. village of Westmoreland, 2 m. S. of meeting-house, white, green, purple, constituting a vein in quartz; at the Notch in the White Mts., green oct. in quartz, rare. In *Vermont*, at Putney, in green cubes. In *Massachusetts*, at the Southampton lead mine. In *Connecticut*, at Trumbull, the *chlorophane* var., with topaz; at Plymouth, in octahedral and dodecahedral crystals; at Willimantic, purple, in a vein in gneiss, and also sparingly at the topaz vein; at the Middletown lead mine. In *New York*, in Jefferson Co., at Muscolonge lake, formerly abundant, in gigantic cubes, sometimes modified, of grass-green and pale-green shades, in granular limestone; in St. Lawrence Co., at Rossie and Johnsburgh, rarely in fine crystals; also at Macomb, where a large cave was recently opened (cf. Kunz, Am. J. Sc., **38**, 72, 1889), lined with cubic crystals, of a sea-green color, from 1 to 6 inches in diameter, some of the groups weighing 1000 pounds and the whole cavity estimated to contain 15 tons; at Lockport, occasionally in cubes, with selenite and celestite in limestone; also similarly near Rochester and Manlius; Amity, in thin seams, with spinel and tourmaline; at Brewster, at the iron mine in colorless to purple crystals, sometimes dodecahedral. In *New Jersey*, near the Franklin Furnace, Sussex Co. In *Virginia*, near Woodstock, in limestone; on the Potomac, at Shepardstown, in white limestone; at the mica mines of Amelia Court House, Amelia Co., a finely phosphorescent variety of green or purple color. In *Illinois*, Gallatin Co., for 30 m. along the Ohio, 10 to 15 m. below Shawneetown, and at other places, dark purple, often in large crystals, in Carboniferous limestone, with galena, and through the soil. In *Missouri*, in cavities in limestone at St. Louis, with calcite, dolomite, millerite. In *California*, at Mt. Diablo, rare in white cubes. In *Arizona*, in Castle Dome dist., white, pink, green, purple. In *Nova Scotia*, at Mabou harbor, green. Near Lake Superior, a few miles from the N.E. corner of Thunder Bay, in large violet cubes on amethyst, affording magnificent specimens.

**Alt.**—Fluorite is slightly soluble in waters containing calcium bicarbonate in solution. The alkaline carbonates decompose it, producing calcium carbonate or *calcite*, and a subsequent change of the calcite may produce other forms of pseudomorphs. Fluorite occurs changed to quartz, by substitution, and also to limonite, hematite, lithomarge, psilomelane, calamine, smithsonite, cerussite, kaolinite.

**Artif.**—Made by Scheerer and Drechsel in crystallized forms, J. pr. Ch., **7**, 63, 1873.

**Ref.**—[1] Klocke, monograph, Ber. Ges. Freib., **6**, No. 4, 1876, who gives early authorities, etc. Dx. adds the vicinal (40·1·0); Gdt. includes also $\epsilon$ (510), $\nu$ (12·1·1). Index, **2**, 51, 1888. Cf. Grailich, Kr. Opt. Unt., 70, 1858, on peculiar distorted forms. [2] Lsx., Jb. Min., 134, 1875. [3] Id., Zs. Kr., **1**, 359 seq., 1877. Kr., **7**, 449, 1883. *Hardness*, Exner, Härte Kryst., 31, 1873. *Pyro-electricity*, *Photo-electricity*, etc., Hankel, Wied., **2**, 66, 1877, **11**, 269, 1880. *Elasticity*, Klang, Wied., **12**, 321, 1881; Voigt, Jb. Min., Beil.-Bd., **4**, 236, 1885.

Bruiachite *Macadam*, Min. Mag., **7**, 42, 1886. Incrusts barite at Loch Bruithaich, Inverness-shire, Scotland. It was first noted by T. D. Wallace, ib., **6**, 169, 1885; its identity with fluorite was shown by Heddle, ib., **8**, 274, 1889.

Gunnisonite *Clarke* and *Perry*, Am. Ch. J., **4**, 140, 1882. Massive, deep purple; color of powder the same. Easily scratched by a knife. G. = 2·85. Analysis by E. A. Kebler, after deducting 12·75 p. c. admixed $CaCO_3$: $CaF_2$ 74·89, CaO 11·44, $SiO_2$ 6·87, $Al_2O_3$ 5·95, $Na_2O$ 0·85 = 100. From near Gunnison, Colorado. Probably an altered or impure fluorite.

**176. CHLOROMAGNESITE.** Cloruro di Maguesio *A. Scacchi*, Mem. Incend. Vesuv., 181, 1855. Cloromagnesite *Id.*, Att. Acc. Napoli, **6**, 1873.

Magnesium chloride, $MgCl_2$; found with other deliquescent salts of Vesuvius.

**177. SELLAITE.** *Strüver*, Att. Acc. Torino, **4**, 35, 1868.

Tetragonal. Axis $\dot{c} = 0·6596$; 001 ∧ 101 = 33° 24½′ A. Sella[1].

| | | | | | |

The form of sellaite is near that of the species of the Rutile Group, p. 233.

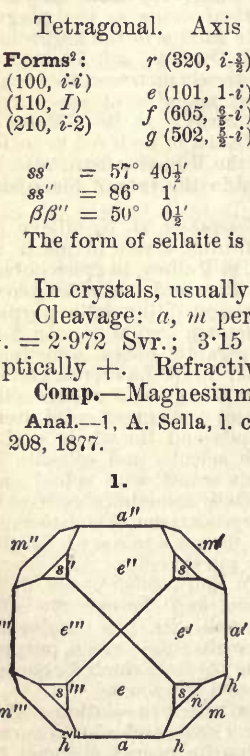
In crystals, usually prismatic in habit and somewhat fibrous in structure.

Cleavage: *a*, *m* perfect; also *e* (Mld.). Fracture conchoidal. Brittle. H. = 5. G. = 2·972 Svr.; 3·15 Sella. Luster vitreous, brilliant. Colorless, transparent. Optically +. Refractive indices: $\omega_D = 1·3780$, $\epsilon_D = 1·3897$, Sella.

**Comp.**—Magnesium fluoride, $MgF_2$ = Fluorine 61·4, magnesium 38·6 = 100.

**Anal.**—1, A. Sella, l. c. 2, 3, A. Cossa, on the corresponding artificial compound, Zs. Kr., **1**, 208, 1877.

1.



Sellaite, after Strüver.

| | | | F | Mg | |
|---|---|---|---|---|---|
| 1. | Gebroulaz glacier | G. = 3·15 | [61·58] | 38·42 | = 100 |
| 2. | *Artif.* | G. = 2·857 | [60·79] | 39·21 | = 100 |
| 3. | “ | | [61·06] | 38·94 | = 100 |

The natural mineral gave Strüver 39·64 p. c. Mg.

**Pyr., etc.**—B.B. in small fragments fuses with intumescence. Insoluble in water; also in acids, except concentrated sulphuric acid: with this it evolves hydrogen fluoride.

**Obs.**—Found embedded in anhydrite or in sulphur, also associated with albite, dolomite, magnesite, fluorite, celestite; from the moraine of the Gebroulaz glacier in Savoy near Moutiers, north of Modane.

Named after the Italian mineralogist and statesman, Quintino Sella (1827–1884).

**Artif.**—Formed artificially by A. Cossa (l. c.) in short prismatic or tabular crystals, with *a*, *m*; sometimes twins ‖ *e*. H. = 6. G. = 2·857. Phosphorescent, with a violet light in a powerful induction-current, which is also true of the natural compound. Difficultly fusible.

**Ref.**—[1] Mem. Acc. Linc., **4**, 455, 1887; Strüver obtained $\dot{c} = 0·6619$, Att. Acc. Torino, **12**, 59, 1876. Cf. also Mld., Bull. Soc. Min., **11**, 302, 1888. [2] Cf. Strüver. [3] A. Sella, l. c., also some other doubtful forms.

**178. LAWRENCITE.** *Daubrée,* C. R., **84**, 69, 1877. Eisenchlorür *Germ.*

Solid, becoming soft on exposure. Color green to brown.

**Comp.**—Ferrous chloride, $FeCl_2$ = Chlorine 55·9, iron 44·1 = 100.

**Obs.**—Present in meteoric irons, as those of Tazewell Co., Tenn., and Rockingham Co., N. C., as identified by J. Lawrence Smith (1818–1883), Am. J. Sc., **19**, 159, 1855, ib., **13**, 214, 1877, after whom the species is named. Probably also present in the Greenland native iron (Daubrée). Drops of ferric chloride, $FeCl_3$ (cf. molysite), formed from lawrencite, often exude in drops (*stagmatite*, Daubrée) from the surface of meteoric irons.

The existence of this substance at Vesuvius was announced by Monticelli and Covelli. The artificial $FeCl_2$ is hexagonal, uniaxial.

**179. SCACCHITE.** Protocloruro di Manganese *A. Scacchi,* Mem. Incend. Vesuv., 181, 1855. Scacchite *Adam,* Tabl. Min., 70, 1869.

Manganese protochloride, $MnCl_2$ = Chlorine 56·4, manganese 43·6 = 100. A deliquescent salt observed with magnesium chloride and other salts at Vesuvius.

Chloralluminite. Cloralluminio *A. Scacchi,* Att. Accad. Napoli, **6** (read Dec. 13, 1873). Aluminium chloride ($AlCl_3 + xH_2O$), produced with molysite and chloromagnesite, at Vesuvius, at the eruption of April, 1872.

**180. COTUNNITE.** Cotunnia *Monticelli & Covelli,* Prodr. Min. Vesuv., 1825. Cotunnite *Kbl.,* Char., **2**, 179, 1830. Lead chloride. Chlorblei *Germ.*

Orthorhombic. Axes $\breve{a} : \bar{b} : \dot{c}$ = 0·9976 : 1 : 1·6805 Schabus[1].
100 ∧ 110 = 44° 56′, 001 ∧ 101 = 59° 18¼′, 001 ∧ 011 = 59° 14¾′.

**Forms:** *b* (010, $i\text{-}\breve{i}$) *e* (120, $i\text{-}\breve{2}$) *μ* (102, $\frac{1}{2}\text{-}\bar{i}$) *p* (111, 1)
*a* (100, $i\text{-}\bar{i}$) *c* (001, *O*) *u* (104, $\frac{1}{4}\text{-}\bar{i}$) *v* (101, $1\text{-}\bar{i}$) *q* (122, $1\text{-}\breve{2}$)

*ee′* = 53° 14½′ *vv′* = 118° 37′ *pp′* = 81° 29′ *qq′* = 46° 36′
*uu′* = 45° 40½′ *ap* = *49° 15½′ *pp″* = 134° 24½′ *qq″* = 123° 58½′
*μu′* = 80° 13′ *pp‴* = *81° 15′ *qq‴* = 104° 14′

In acicular crystals. Also in semi-crystalline masses. Cleavage: *a*, perfect. Soft; scratched by the nail. G. = 5·238; 5·83 Rg. Luster adamantine; inclining to silky or pearly. Color white, also yellowish or with a tinge of green. Streak white.

**Comp.**—Lead chloride, $PbCl_2$ = Chlorine 25·5, lead 74·5 = 100.

**Anal.**—1, 2, Scacchi, Not. Min., I, p. 39 (Att. Acc. Nap., March 12, 1870): 1, wax-yellow var.; 2, white laminæ. Traces of fluorine are present.

| | Cl | Pb | |
|---|---|---|---|
| 1. | 25·36 | 74·98 | = 99·65 |
| 2. | 25·33 | 73·98 | = 99·31 |

**Pyr., etc.**—B.B. on charcoal fuses readily, spreading out on the coal and volatilizing, gives a white coating, the inner edge of which is tinged yellow from lead oxide; the coating in R.F. disappears, tingeing the flame azure; with soda gives metallic lead. Added to a salt of phosphorus bead, previously saturated with copper oxide, gives the reaction for chlorine (see cerargyrite). Soluble in about 22 parts of hot water.

**Obs.**—Found by Monticelli and Covelli, in the crater of Vesuvius, after the eruption of 1822, accompanied by sodium chloride, and chloride and sulphate of copper; also by Scacchi and Guiscardi on the lava of 1855, and by Scacchi on that of 1868 (l. c.). Occurs massive with other lead minerals, Mt. Challacollo, Tarapacá, Chili.

Named after Dr. Cotugno of Naples.

**Ref.**—[1] On artif. cryst., Ber. Ak. Wien, **4** (1), 456, 1850; with Miller (Min., p. 616), *μ* = 110, *e* = 011, *q* = 111, etc.; the crystals deviate at most but 3 or 4 minutes from the tetragonal type, and are near calomel in angle, as noted by Schrauf.

Pseudocotunnite. Pseudocotunnia *A. Scacchi,* Att. Accad. Napoli, **6**, 1873 (Contrib. Min., II, 38). Observed in acicular yellow opaque crystals, destitute of luster, accompanying cotunnite, at Vesuvius, as a result of the eruption of 1872. Composition believed to be $PbCl_2.KCl$, but uncertain.

**181. MOLYSITE.** Eisenchlorid *Hausm.,* 1819, Handb., 1463, 1847. Molisite *Scacchi.* Molysite *Dana,* Min., 5th Ed., 1868, p. 118.

Incrusting. Color brownish red, light or dark, and yellow.

**Comp.**—Ferric chloride, $FeCl_3$ = Chlorine 65·5, iron 34·5 = 100.

**Obs.**—Noticed by Hausmann at Vesuvius in 1819, forming a brownish red incrustation on lavas; and by Scacchi in the same region, as a result of recent eruptions (Eruz. Vesuv., 1850–55, Min. Contrib. Vesuv., II, 43, 1873), who attributes the yellow color of the lavas about the fumaroles or steam-holes partly to this species; by its decomposition a reddish brown deposit, insoluble in water, is formed.

Named from μόλυσις, *stain*, in allusion to its staining the lavas.

The artificial salt, $FeCl_3$, is hexagonal.

**182. TYSONITE.** *Allen* and *Comstock*, Am. J. Sc., **19**, 390, 1880. Fluocerite pt.

Hexagonal. Axis $\dot{c} = 0{\cdot}68681$; $0001 \wedge 10\bar{1}1 = {}^*38° 25'$ E. S. Dana[1].

**Forms:** *c* (0001, *O*); *a* (11$\bar{2}$0, *i*-2), *m* (10$\bar{1}$0, *I*); *p* (10$\bar{1}$1, 1), *q* (20$\bar{2}$1, 2); *s* (11$\bar{2}$1, 2-2).

Angles: *cq* = 57° 46′, *cs* = 53° 57′, *pp′* = 36° 12′, *ms* = 45° 34′, *ps* = 26° 20′.

In thick prisms with *c a m*, also tabular; crystals mostly altered to bastnäsite. Also massive, cleavable.

Cleavage: *c* perfect. Fracture subconchoidal. Brittle. H. = 4·5–5. G = 6·12–6·14. Luster vitreous to resinous, on cleavage surface somewhat pearly. Color pale wax-yellow, when fresh, changing to yellowish and reddish brown. Transparent to translucent. Optically negative.

**Comp.**—A fluoride of the cerium metals, $(Ce,La,Di)F_3$, ratio of Ce : La(Di) = 14 : 11.

**Anal.**—Allen and Comstock, l. c.

| | | |
|---|---|---|
| $\frac{2}{3}$ Ce 40·19[a] | La,Di 30·37[b] | F [29·44] = 100·00 |
| [a] Atomic weight 141·2. | [b] Joint atomic weight 138. | |

**Pyr., etc.**—B.B. blackens, but does not fuse. In closed tube decrepitates, changes color to a light pink. Insoluble in hydrochloric and nitric acids, but soluble in sulphuric acid, with evolution of hydrogen fluoride.

**Obs.**—Tysonite occurs in feldspar in the Pike's Peak region, El Paso Co., Colorado.

The original *fluocerite* occurs at Finbo and Broddbo near Falun, in Sweden, embedded in quartz and albite, accompanying pyrophysalite and allanite; it is described as being hexagonal with basal cleavage. The Broddbo mineral occurs in crystals with *cq* = 61° 2′ (A.Nd.). There seems every probability that this mineral is identical with tysonite, although the imperfect analysis of Berzelius (5th Ed., p. 126) has left its composition in doubt. The fluocerite from Österby, analyzed by Weibull and Tedin, seems to be quite distinct, see p. 175.

**Alt.**—Commonly altered to the fluocarbonate called bastnäsite (hamartite, or hydrofluocerite), p. 291.

**Ref.**—[1] Am. J. Sc., **27**, 481, 1884. The mineral from Broddbo, Sweden, called fluocerite by Nordenskiöld (see above) probably belongs here; he found $0001 \wedge 20\bar{2}1 = 61° 2'$, Öfv. Ak. Stockh., **27**, 550, 1870.

**183. CRYOLITE.** Chryolith, Thonerde mit Flussäure *Abildgaard*, Scherer's J., **2**, 502, 1799; d'Andrada, ib., **4**, 37, 1800. Kryolith *Karst.*, Tab., 28, 73, 1800; id. (with anal.), *Klapr.*, J. de Phys., **51**, 473, 1800, Beitr., **3**, 207, 1802; *Vauq.*, Ann. Ch., **37**, 89, 1801. Alumine fluatée alcaline, *H.*, Tr., **2**, 1801. Cryolite. Eisstein *Germ.*

Monoclinic. Axes $\grave{a} : \bar{b} : \dot{c} = 0{\cdot}96626 : 1 : 1{\cdot}38824$; $\beta = 89° 49' = 001 \wedge 100$ Krenner[1].

$100 \wedge 110 = 44° 1'$, $001 \wedge 101 = 55° 2\frac{1}{6}'$, $001 \wedge 011 = {}^*54° 14'$.

Twins[3]: tw. pl. (1) *m*, contact-twins with $m\underline{m} = 3^\circ\ 56'$, also as polysynthetic lamellæ resembling plagioclase; (2) *z* (112) contact-twins, and since $cz = mz$ nearly, the prism of one individual sensibly coincides with the base of the other, while the other prismatic faces unite in a diagonal line at a very obtuse angle; also (with tw. pl. $\bar{1}12$) shown as enclosed lamellæ, which may be produced by application of heat. (3) *a*, with *c*-face nearly ‖ *m*, seen in enclosed lamellæ; and perhaps also (4) *c*. Crystals often cubic in aspect and grouped in parallel position. Faces *m* striated ‖ edges *m*/*r*, *m*/*v*, also *m*/*c*. Massive, cleavable.

Cleavage: *c* most perfect, also *m*, *k* somewhat less so. Fracture uneven. Brittle. H. = 2·5. G. = 2·95–3·0. Luster vitreous to greasy; somewhat pearly on *c*. Colorless to snow-white, sometimes reddish or brownish to brick-red or even black. Transparent to translucent.

Optically +. Double refraction weak. Ax. pl. ⊥ *b*; $Bx_a \wedge \dot{c} = -43^\circ\ 54'$ in white light. Dispersion $\rho < v$; also horizontal. Axial angles:

$$2E_r = 58^\circ\ 50' \quad 2E_y = 59^\circ\ 24' \quad 2E_{bl} = 60^\circ\ 10' \text{ Krenner}^4.$$

Refractive index (for a prism with edge ‖ $Bx_o$) = 1·364 Na, Knr.; also 1·3343 Websky[5], or differing but little from that of water. On etching-figures, cf. Baumhauer[6].

**Comp.**—A fluoride of sodium and aluminium, $Na_3AlF_6$ or $3NaF.AlF_3$ = Fluorine 54·4, aluminium 12·8, sodium 32·8 = 100. A little iron sesquioxide is sometimes present as impurity.

**Anal.**—1, 2, Brandl, Zs. Kr., **7**, 386, 387, 1883. 3, Hillebrand, Bull. **20**, U. S. G. Surv., p. 48, 1885.

**Pyr., etc.**—Fusible in small fragments in the flame of a candle. B.B. in the open tube heated so that the flame enters the tube gives off hydrofluoric acid, etching the glass; the water which condenses at the upper end of the tube reacts for fluorine with Brazil-wood paper. In the forceps fuses very easily, coloring the flame yellow. On charcoal fuses easily to a clear bead, which on cooling becomes opaque; after long blowing, the assay spreads out, the fluoride of sodium is absorbed by the coal, a suffocating odor of fluorine is given off, and a crust of alumina remains, which, when heated with cobalt solution in O.F., gives a blue color. Soluble in sulphuric acid, with evolution of hydrofluoric acid. Slightly soluble in water, 1 part in 2730 at 12° C., Johnstrup.

**Obs.**—Occurs in a bay in Arksuk-fiord, in West Greenland, at Ivigtut (or Evigtok), about 12 m. from the Danish settlement of Arksuk, where it constitutes a large bed in a granitic vein in a gray gneiss. The crystals occur in cracks in the massive mineral. The first specimens of cryolite came through Denmark from Greenland, and the earliest notice of it was by Schumacher in the Abh. Nat. Ges. Copenhagen, **4**, 1795. The locality was described from personal observation by Giesecke in Ed. Encyc., **10**, 97, and Ed. Phil. J., **6**, 141, 1822; by J. W. Tayler in the Q. J. G. Soc., **12**, 140; and more recently by Johnstrup (Förh. Skand. Nat., **12**, 234, 1880). Johnstrup finds the cryolite limited to the granite; he distinguishes a central and a peripheral part; the former has an extent of 500 feet in length and 1000 feet in breadth and consists of cryolite chiefly, with quartz, siderite, galena, sphalerite, pyrite, chalcopyrite, and wolframite irregularly scattered through it. The peripheral portion forms a zone about the central mass of cryolite; the chief minerals are quartz, feldspar, and ivigtite, also fluorite, cassiterite, molybdenite, arsenopyrite, columbite. Its inner limit is rather sharply defined, though there intervenes a breccia-like portion consisting of the minerals of the outer zone enclosed in cryolite; beyond this it passes into the surrounding granite without distinct boundary. Also occurs sparingly near Miask, in the Ilmen Mts., in a topaz mine with chiolite (and chodneffite).

Cryolite and its alteration products, pachnolite, thomsenolite, prosopite, etc., also occur in very limited quantity at the southern base of Pike's Peak, El Paso county, Colorado, north and west of Saint Peter's Dome; they are found in vein-like masses of quartz and microcline embedded in granite; zircon, astrophyllite, and columbite are associated minerals. Also reported from the Yellowstone Park (Min. Res. U. S., 1886, p. 693).

Named from κρύος, *frost*, λίθος, *stone*, hence meaning *ice-stone*, in allusion to the translucency of the white cleavage masses.

**Artif., Alt.**—On artificial alteration products, showing that the sodium may be replaced by the alkaline earths (Ca, Mg, etc.), see Noellner, Zs. G. Ges., **33**, 139, 1881. The related minerals, pachnolite, thomsenolite, etc., are largely secondary products due to the alteration of the original cryolite.

**Ref.**—[1] Nat. Ber. aus Ungarn, **1**, 151, 1883. Cryolite, at first regarded as orthorhombic, was made triclinic by Des Cloizeaux, Propr. Opt., **1**, 64, 1857, N. R., p. 201, 1867, and by Websky, Jb. Min., 810, 1867; cf. also Dx., Bull. Soc. Min., **6**, 254. 1883, and Groth, Zs. Kr., **10**, 642, 1886. [2] Knr., l. c. [3] See Mgg., Jb. Hamb., **1**, 67. 1883–84, Zs. Kr., **11**, 167, 170, 1885; also Cross and Hillebrand, Bull. **20**, U. S. Geol. Surv., 45, 1885. [4] Knr., l. c. [5] Websky, l. c. [6] Zs. Kr., **11**, 133, 1885.

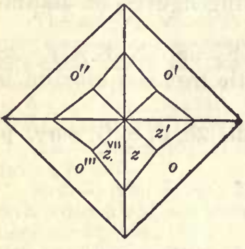
ELPASOLITE *Cross* and *Hillebrand*, Am. J. Sc., **26**, 283, 1883; Bull., **20**, U. S. Geol. Surv. p. 57, 1885. Massive or showing an indistinct isometric form; optically isotropic. Colorless to white. An imperfect analysis (Hillebrand) gave:

F 46·98 (calc.) Al 11·32 Ca 0·72 Mg 0·22 K 28·94 (approx.) Na 9·90 (approx.) = 98·08

This suggests a composition analogous to cryolite with sodium in part replaced by potassium. Occurs sparingly in cavities in the massive pachnolite from the Pike's Peak region, El Paso county, Colorado.

**184. CHIOLITE.** Chiolith (fr. Miask) *Hermann & Auerbach*, J. pr. Ch., **37**, 188, 1846. Arksutite *G. Hagemann*, Am. J. Sc., **42**, 94, 1866.

Tetragonal. Axis $\dot{c}$ = 1·0418; 001 ∧ 101 = 46° 10⅓′ Koksharov[1].



In small pyramidal crystals, *o* (111, 1), with an undetermined zirconoid, *z*, and rarely *c* (001, *O*). Angles: *oo′* =*71° 37′, *oo″* = 111° 40⅙′.

Twins: tw. pl. *o*, contact-twins sometimes prismatic in aspect. Distinct crystals rare and very small. Usually massive granular, resembling cryolite; structure crystalline.

Cleavage: *o*? H. = 3·5–4. G. = 2·84–2·90 Rg.; 2·99 Lindström. Color snow-white. Luster vitreous. Transparent to translucent. Optically negative, Dx., Knr.

**Comp.**—A fluoride of aluminium and sodium, $5NaF.3AlF_3$ = Fluorine 57·7, aluminium 17·5, sodium 24·8 = 100, Groth-Brandl.

**Anal.**—1, Brandl, Zs. Kr., **7**, 478, 1883. 2, 3, G. Lindström, G. För. Förh., **8**, 172, 1886.

| | | F | Al | Na |
|---|---|---|---|---|
| 1. Miask | | 57·30 | 17·66 | 24·97 = 99·93 |
| 2. Ivigtut | G. = 2·994 | 57·16[a] | 17·28 | 24·72 Ca 0·22, Mg 0·05 = 99·43 |
| 3. " | | 57·74[a] | 17·68 | 24·49 Mg 0·11 = 100·02 |

[a] Calculated.

Earlier analyses (5th Ed., p. 128) on less pure material were made by Hermann and Rammelsberg. The analysis of Hagemann, upon which "arksutite" was based, was shown by Groth (Zs. Kr., **7**, 479, 1883) to be untrustworthy, and the identity of the mineral with chiolite was later established by Nordenskiöld on the strength of Lindström's analysis (l.c.); cf. also Krenner, who noted the resemblance in form, Nat. Ber. aus Ungarn, **1**, 170, 1883.

**Pyr.**—Like cryolite, but somewhat more fusible.

**Obs.**—From the Ilmen Mts., near Miask, where it occurs in granite, with topaz, fluorite, phenacite, and cryolite. Also with cryolite at Ivigtut, Greenland, in white granular masses, occasionally showing cleavage.

Named from χιών, *snow*, λίθος, *stone*, in allusion to its appearance and similarity to cryolite (= *ice-stone*).

**Ref.**—[1] Vh. Min. Ges., p. 1, 1850–51; Min. Russl., **4**, 393. Cf. Kenng., Ber. Ak. Wien, **11**, 980, 1853, who made the crystals orthorhombic.

CHODNEFFITE. Chiolith (fr. Miask) *v. Wörth & Chodnev*, Vh. Min. Ges., 1845–46, 208, 216, 1846. Chodneffite *Dana*, Min., 234, 1850; Cryolite, ib., 97, 1854. Chodnewit. Nipholith *Naum.*, Min., 219, 1864.

Separated from chiolite on the basis of analyses by Chodnev and Rammelsberg (5th Ed., p.

129); but as shown by Groth, the differences are almost certainly due to want of purity in the material analyzed. The formula deduced (and still preferred, Rg.) for chiolite was $3NaF.2AlF_3$; that for chodneffite, $2NaF.AlF_3$.

**185. HIERATITE.** *A. Cossa*, Trans. Acc. Linc., **6**, 141, 1882; Bull. Soc. Min., **5**, 61, 1882.

Isometric. In octahedrons or cubo-octahedrons forming, with scales of sassolite, stalactitic concretions of grayish color and spongy texture.

The concretions contain also selen-sulphur, arsenic sulphide, and the alums of potassium, cæsium, rubidium, and, in small quantities, thallium. They are four-fifths soluble in boiling water, from which, on cooling, a gelatinous precipitate, later becoming crystalline, separates out; the latter consists of isotropic crystals, cubes with octahedral faces.

For these the composition $2KF.SiF_4$ was obtained on analysis = Fluorine 51·9, silicon 12·7, potassium 35·4 = 100.

**Obs.**—From the fumaroles of the crater of Vulcano (Greek name, Hiera), one of the Lipari Islands.

The following fluorides are mentioned by Scacchi as occurring at Vesuvius, Att. Acc. Napoli, **6**, 1873 (Contr. Min., II, 1874):

HYDROFLUORITE. Idrofluore *A. Scc.* Hydrofluoric acid gas (HF) observed especially after the eruptions of 1870, 1872.

PROIDONITE. Proidonina, *A. Scc.* Silicon tetrafluoride ($SiF_4$) observed in the exhalations at the time of the eruption of 1872.

CRYPTOHALITE. Criptoalite, *A. Scc.* A fluo-silicate of ammonium, perhaps $2NH_4F.SiF_4$, observed with sal ammoniac at a Vesuvian fumarole.

## II. Oxychlorides, Oxyfluorides.

### A. Oxychlorides.

| **196. Fluocerite** | $R_2O_3.4RF_3$ | R = Ce, etc. | |

---

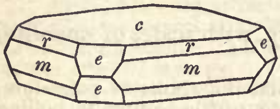
### A. Oxychlorides.

**186. MATLOCKITE.** *R. P. Greg*, Phil. Mag., **2**, 120, 1851. *Rg.*, Pogg., **85**, 144, 1852.

Tetragonal. Axis ć = 1·7627; 001 ∧ 101 = *60° 26′ Miller.

**Forms:** *c* (001, *O*); *m* (110, *I*); *e* (101, 1-*ĭ*); *r* (111, 1).
Angles: *ee'* = 75° 54½', *ee''* = 120° 52', *cr* = 68° 8½', *rr'* = 82° 2', *rr''* = 136° 17', *me* = 52° 3'.

Crystals tabular ‖ *c*. Cleavage: *c* imperfect. Fracture uneven, slightly conchoidal.



H. = 2·5–3. G. = 7·21. Luster adamantine, occasionally pearly. Color clear yellowish, sometimes a little greenish. Transparent to translucent.

**Comp.**—An oxychloride of lead, $Pb_2OCl_2$ or $PbCl_2.PbO$ = Chlorine 14·2, oxygen 3·2, lead 82·6 = 100, or Lead chloride 55·5, lead oxide 44·5 = 100.

**Anal.**—1, R. A. Smith, Phil. Mag., **2**, 120, 1851. 2, Rg., l. c.; he gives Cl 13·38, Pb 82·16, and G. = 5·395; the last cannot be correct.

| | $PbCl_2$ | PbO | | |
|---|---|---|---|---|
| 1. | 55·18 | 44·30 | ign. 0·07 | = 99·55 |
| 2. | 52·45 | 46·42 | | = 98·87 |

**Pyr., etc.**—Like mendipite.

**Obs.**—From an old mine at Cromford near Matlock in Derbyshire, with phosgenite; also, as a sublimation-product, at Vesuvius after the eruption of 1858, R. Cappa, C. R., **50**, 955, 1860. Probably from Mt. Challacollo, Tarapaca, Peru, in crystalline crusts in a quartzose gangue; an analysis, after deducting 32 p. c. quartz, gave: $PbCl_2$ 65·37, PbO 34·63. The excess of lead chloride is attributed to cotunnite, but the identification is incomplete. Raimondi, Min. Pérou, 170, 1878.

**Ref.**—[1] Min., p. 620, 1852.

**187. MENDIPITE.** Saltsyradt Bly (Salzsaures Blei) *Berz.*, Ak. H. Stockh., 184, 1823; Ed. J. Sc., **1**, 379, 1824. New ore of lead from Mendip, Peritomous Lead-baryte, *Haid.*, Min. Mohs, **2**, 151, 1825. Muriate of Lead, Chloride of Lead. Plomb chloruré, pt., *Fr.* Kerasine pt. [rest phosgenite] *Beud.*, Tr., **2**, 502, 1832. Chlor-Spath *Breith.*, Char., 61, 1832. Berzelite *Lévy*, Min. Heul., **2**, 448, 1837. Mendipit *Glock.*, Grundr., 604, 1839.

Orthorhombic. Axes: $\breve{a} : \bar{b}$ = 0·8005 : 1. 100 ∧ 110 = 38° 42' Miller[1].

**Forms:** *a* (100, *i*-*ĭ*), *b* (010, *i*-*ĭ*), *c* (001, *O*), *m* (110, *I*).
Angles: *am* = 38° 42', *mm'''* = 77° 24'.

Occurs in fibrous or columnar masses, often radiated.

Cleavage: *m* highly perfect; *a*, *b* less perfect. Fracture conchoidal to uneven. H. = 2·5–3. G. = 7–7·1. Luster pearly, inclining to adamantine upon cleavage face. Color white, with a tinge of yellow, red, or blue. Streak white. Feebly translucent to opaque.

**Comp.**—$Pb_3O_2Cl_2$ or $PbCl_2.2PbO$ = Chlorine 9·8, oxygen 4·4, lead 85·8 = 100, or Lead chloride 38·4, lead oxide 61·6 = 100. Analyses see 5th Ed., p. 120.

**Pyr., etc.**—In the closed tube decrepitates and becomes more yellow. B.B. on charcoal fuses easily, and is reduced to metallic lead with elimination of acid vapors, giving the coal a white coating of lead chloride, the inner edge of which is yellow from lead oxide. With salt of phosphorus bead, previously saturated with oxide of copper, colors the O.F. azure-blue. Soluble in nitric acid.

**Obs.**—Formerly found near Churchill in the Mendip Hills, Somersetshire, in small radiated crystalline masses with galena on earthy black manganese; also occurs at mine Kunibert near Brilon in Westphalia. Reported in opaque white crystals from Tarnowitz, Silesia; these, however, have been shown to be altered phosgenite.

**Ref.**—[1] Mlr., Min., 621, 1852.

**188. SCHWARTZEMBERGITE.** Oxychloroïodure de plomb (fr. Atacama) *Domeyko*, Ann. Mines, **5**, 453, 1864; Plomo oxichloro-ioduro, Min. Chili. Schwartzembergite *Dana*, 1868. Plumbiodite *Adam*, Tabl. Min., 67, 1869.

Rhombohedral. Optically uniaxial, negative, Btd.[1] In druses of small crystals. Also in thin amorphous crusts, compact, passing into earthy.

Brittle. H. = 2–2·5. G. = 6·2–6·3 Liebe. Luster adamantine. Color honey-yellow, when purest; also straw-yellow, inclining to lemon-yellow, sometimes a little reddish. Streak straw-yellow.

**Comp.**—Probably $Pb(I,Cl)_2.2PbO$, with I : Cl = 3 : 2. This requires: Lead chloride 13·4, lead iodide 33·1, lead oxide 53·5 = 100.

**Anal.**—Liebe, Jb. Min., 159, 1867:

| $PbCl_2$ | $PbI_2$ | $PbO$ | $PbSO_4$ | $PbCO_3$ | $Sb_2O_3$ |
|---|---|---|---|---|---|
| 11·40 | 30·89 | 48·92 | 5·51 | 1·88 | 0·91 = 99·51 |

Liebe regards all the ingredients as impurities except the iodide and oxide of lead.

**Pyr., etc.**—Very fusible, like cerargyrite; in fusing loses its color; on charcoal metallic globules. In a matrass abundant violet vapors of iodine. No effervescence with nitric acid, but loses color, becoming first brownish and then white, and, if some water be added, it dissolves completely on heating.

**Obs.**—Forms crusts on galena at a mine 15 leagues from the port of Paposo in the desert of Atacama, where it was discovered by Mr. Schwartzemberg. At the San Rafaël mine in Bolivia; Sierra Gorda, in Peru.

**Ref.**—[1] Bull. Soc. Min., 4, 87, 1881.

### 189. LAURIONITE. *Köchlin*, Ann. Mus. Wien, 2, 188, 1887.

Orthorhombic. Axes $\breve{a} : \bar{b} : \dot{c} = 0·7328 : 1 : 0·8315$ Köchlin[1].

$100 \wedge 110 = 36° 14'$, $001 \wedge 101 = 48° 36\frac{2}{3}'$, $001 \wedge 011 = 39° 44\frac{2}{3}'$.

**Forms:** *a* (100, *i*-ī), *b* (010, *i*-ĭ), *c* (001, *O*); *l* (210, *i*-2̄), *m* (110, *I*), *n* (120, *i*-2̆); *d* (012, ½-ĭ); *p* (151, 5-5̆); also uncertain 410, 320, 340, 160, and a pyramid near 141.

*ll'''* = 40° 15'  *nn'* = 68° 37'  *bd* = *67° 25½'  *pp''* = 153° 52'
*mm'''* = 72° 28'  *dd'* = 45° 9'  *pp'* = 29° 44'  *pp'''* = 140° 1'
*bm* = *53° 46'

In minute prismatic crystals flattened ∥ *b*; faces *b* with feather-like striations ∥ edge *b*/*p*.

Cleavage: *a* distinct; perhaps also *c*. H. = 3–3·5. Luster adamantine, on *a* silky. Colorless. Transparent.

**Comp.**—$PbClOH$ or $PbCl_2.Pb(OH)_2$ = Chlorine 13·7, oxygen 3·1, lead 79·7, water 3·5 = 100, or Lead chloride 53·5, lead oxide 43·0, water 3·5 = 100.

**Anal.**—Bettendorff, Ber. nied. Ges., p. 153, 1887.

| Cl | O | Pb | $H_2O$ | |
|---|---|---|---|---|
| 13·77 | 3·17 | 79·38 | 3·68 | = 100 |

**Pyr.**—B.B. fuses easily and quietly to a yellowish opaque bead; on charcoal with soda a lead globule. Soluble in nitric acid, also in part in hot water when in powder. The water is driven off above 142° C.

**Obs.**—Occurs in groups of crystals together with phosgenite and cerussite in cavities of lead slag at Laurion, Greece, as a result of the action of sea-water to which the slag had been exposed for some 2000 years.

**Ref.**—[1] L. c., and ib., 2, 83, 127 (Notizen); the symbol of *p* is erroneously given as (2·10·1). Cf. also Rath, Ber. nied. Ges., p. 150, June 6, 1887.

### 190. DAVIESITE. *L. Fletcher*, Min. Mag., 8, 174, 1889.

Orthorhombic. Axes $\breve{a} : \bar{b} : \dot{c} = 0·7940 : 1 : 0·4777$ Fletcher.

$100 \wedge 110 = *38° 27'$, $001 \wedge 101 = *31° 2'$, $001 \wedge 011 = 25° 32'$.

**Forms:**
*b* (010, *i*-ĭ)
*c* (001, *O*)
*m* (110, *I*)
*d* (101, 1-ī)
*e* (301, 3-ī)
*f* (011, 1-ĭ)
*g* (031, 3-ĭ)
*h* (051, 5-ĭ)
*v* (221, 2)
*t* (211, 2-2̄)
*s* (121, 2-2̆)
*r* (251, 5-$\frac{5}{2}$)

*mm'''* = 76° 54'  *ee'* = 122° 1'  *cv* = 56° 56½'  *br* = 33° 13½'
*dd'* = 62° 4'  *gg'* = 110° 11'  *bt* = 73° 1'  *vv'* = 62° 49'
*ff'* = 51° 4'  *hh'* = 134° 33'  *bv* = 58° 35'  *ss'* = 78° 37'

In minute prismatic crystals; faces *b* sometimes striated horizontally.

No cleavage observed. Fracture subconchoidal. Luster vitreous to adamantine. Colorless. Optically +. Ax. pl. ∥ 100. Bx ⊥ *c*.

**Comp.**—An oxychloride of lead, but exact composition doubtful.

**Pyr.**—Yields metallic lead on charcoal with soda. Readily dissolved in nitric acid, more so than mendipite.

**Obs.**—Occurs sparingly, associated with caracolite and percylite, on a matrix of massive anglesite at the Mina Beatriz, Sierra Gorda, Atacama. Near mendipite in prismatic angle, but without its perfect cleavage, and more easily dissolved in nitric acid.

Named after Thomas Davies, Esq., of the Mineral Department, British Museum.

**191. FIEDLERITE.** *G. vom Rath*, Ber. nied. Ges., p. 154, June 7, 1887.

Monoclinic. Axes $\grave{a} : \bar{b} : \acute{c} = 0{\cdot}81918 : 1 : 0{\cdot}89153$; $\beta = {}^*77° \; 20' = 001 \wedge 100$ Rath.

$100 \wedge 110 = {}^*38° \; 38'$, $001 \wedge 101 = 40° \; 36\frac{1}{3}'$, $001 \wedge 011 = 41° \; 7'$.

**Forms**: *a* (100, $i$-$\bar{\imath}$), *c* (001, *O*); *n* (650, $i$-$\frac{6}{5}$); *m* (110, *I*); *x* ($\bar{5}06$, $\frac{5}{6}$-$\bar{\imath}$), *y* ($\bar{5}03$, $\frac{5}{3}$-$\bar{\imath}$); *o* (111, −1), *u* (544, $-\frac{5}{4}$-$\frac{5}{4}$), *i* (577, $-1$-$\frac{7}{5}$), *p* (5·12·12, $-1$-$\frac{12}{5}$), *e* (5·24·24, $-1$-$\frac{24}{5}$).

Angles: *cx* = 47° 50½′, *cy* = 71° 12′, *co* = 47° 56′, *oo′* = 56° 8′, *ao* = 44° 59′, *mo* = *32° 12′.

Crystals minute, tabular ∥ *a*; twins with tw. pl. *a*. Faces *a* smooth, or with fine striations ∥ edge *a*/*o*; *c* dull.

Cleavage: *c* distinct. Luster adamantine. Colorless. Transparent.

**Comp.**—Contains lead and chlorine, perhaps an oxychloride.

Soluble completely in nitric acid, but less readily than laurionite.

**Obs.**—Occurs with laurionite, wh. see p. 171.

Named after the Saxon Commissioner of Mines, Fiedler, director of the Grecian exploration.

**192. PERCYLITE.** *H. J. Brooke*, Phil. Mag., **36**, 131, 1850.

Isometric. Observed forms:

*a* (100, $i$-$i$) *d* (110, $i$) *o* (111, 1) *e* (210, $i$-2)

Crystals minute cubes, other forms rare. Also massive.

H. = 2·5. Color and streak sky-blue.

**Comp.**—A hydrated oxychloride of lead and copper, perhaps $PbCuO_2H_2Cl_2$ = Chlorine 18·9, oxygen 4·3, lead 55·1, copper 16·9, water 4·8 = 100.

An analysis by Flight, but of very impure material, gave: Cl 13·37, Cu 8·78, Pb 37·64, $H_2O$ 2·87, Ag 8·98, $PbSO_4$ 22·98, O *undet.*, $CO_2$ 1·39 = 96·01. J. Ch. Soc., **25**, 1051, 1872.

**Pyr.**—In the closed tube yields water and odorless fumes. B.B. tinges the flame green with blue on the edges. With borax reacts for copper.

**Obs.**—The original mineral was found with gold, and supposed to be from Sonora, Mexico. Since obtained from South Africa with anglesite, cerussite, and cerargyrite. Also at the Mina Beatriz, Sierra Gorda, Atacama, with caracolite, daviesite, and numerous other lead salts, and perhaps Mina San Rafaël, Galeria del Norte, Bolivia, and Mt. de Challacolla, Tarapacá, Chili.

Named after Dr. John Percy, the English metallurgist (1817–1889). See Boléite, p. 1028.

**193. ATACAMITE.** Sable vert cuivreux du Pérou, Chaux cuivreuse unie à un peu d'acide muriatique et d'eau, *Rochefoucauld, Baumé & Fourcroy*, Mem. Ac. Paris, 1786 (pub'd in 1788); *Berthollet*, ib., 474 (note added in 1788). Kupfersand, Salzsaures Kupfer, *Karst.*, Tab., 46, 76, 1800. Cuivre muriaté *H.*, *Tr.*, 1801. Muriate of copper. Atacamit, Salzkupfererz, *Blumenbach*, Handb. Nat., 1805. Kupferhornerz, Atacamit, *Ludwig*, Min., 2, 178, 1804. Smaragdochalcit *Hausm.*, Handb., 1039, 1813. Halochalzit *Breith.*, Handb., 165, 1841. Remolinite *B. & M.*, Min., 618, 1852. Marcylite *Shep.*, Marcy's Expl. Red River, 135, 800, Washington, 1854, Am. J. Sc., **21**, 206, 1856; *Dana*, ib., **24**, 122, 1857. Botallackite *A. H. Church*, J. Ch. Soc., **18**, 212, 1865.

Orthorhombic. Axes $\breve{a} : \bar{b} : \acute{c} = 0{\cdot}66126 : 1 : 0{\cdot}75149$ Zepharovich-Klein[1].

$100 \wedge 110 = 33° \; 28\frac{1}{2}'$, $001 \wedge 101 = 48° \; 39\frac{1}{4}'$, $001 \wedge 011 = 36° \; 55\frac{1}{2}'$.

**Forms**[2]:
*a* (100, $i$-$\bar{\imath}$)
*b* (010, $i$-$\breve{\imath}$)
*c* (001, *O*)

*m* (110, *I*)
*t* (560, $i$-$\frac{6}{5}$)
*l* (230, $i$-$\frac{3}{2}$)
*s* (120, $i$-$\breve{2}$)
*k* (130, $i$-$\breve{3}$)

*x* (140, $i$-$\breve{4}$)
*u* (101, 1-$\bar{\imath}$)
*d* (201, 2-$\bar{\imath}$)[3]

From anal. 5–11, the impurities have been deducted. Darapsky (l. c.) gives a discussion of the variation in composition.

Analyses of an ore from Cobija, Bolivia, and of botallackite give half more water (see 5th Ed.). Liversidge obtained for a crystallized specimen from New South Wales 69·9 p. c. CuO and 14·3 $CuCl_2$ (Proc. Roy. Soc., N. S. W., Nov. 3, 1880).

**Pyr., etc.**—In the closed tube gives off much water, and forms a gray sublimate. B.B. on charcoal fuses, coloring the O.F. azure-blue, with a green edge, and giving two coatings, one brownish and the other grayish white; continued blowing yields a globule of metallic copper; the coatings, touched with the R.F., volatilize, coloring the flame azure-blue. In acids easily soluble.

**Obs.**—This species was originally found in the state of sand in the Atacama province, northern part of Chili. It occurs in different parts of Chili, especially at Los Remolinos; also in veins in the district of Tarapaca, Bolivia; at Tocopilla, 16 leagues north of Cobija, an important locality, in Bolivia; with malachite at Wallaroo in South Australia; in New South Wales, probably at the Cobar mines, Robinson Co.; in the Nellore district, India; at the malachite locality in the Serra do Bembe, near Ambriz, on the west coast of Africa; at the Estrella mine in southern Spain· at St. Just in Cornwall, in crusts and stalactitic tubes. In large pseudomorphous crystals, 2 inches long, altered to malachite, at the Medno-Rondiansky mine near Nizhni Tagilsk and in the Turginsk mines. In the U. S., with cuprite, gerhardtite, etc., at the United Verde mine, Jerome, Arizona.

Botallackite occurs at the Botallack mine, Cornwall, in thin crusts of minute interlacing crystals, closely investing killas; Schwarzenberg in Saxony; also supposed to invest some of the lavas of Vesuvius, but questioned by Scacchi, the mineral so called being a basic sulphate (Mem. Incend. Vesuv., 1855).

Atacamite is sometimes ground up in Chili, and sold under the name of *Arsenillo* as sand for letters.

**Alt.**—Occurs altered to malachite, cf. Tschermak (Min. Mitth., 39, 1873), who has imitated this result; also Kk., Bull. Soc. St. Pet., **18**, 186, 1872. Also altered to chrysocolla, cf. Rose, Reis. Ural., **1**, 409, 412, 1837, and Bärwald, Zs. Kr., **7**, 169, 1882.

**Artif.**—On artificial atacamite, see Field, Phil. Mag., **24**, 123, 1862; Debray, Bull. Soc. Ch. **7**, 104, 1866; Friedel, C. R., **77**, 211, 1873; on analogous oxybromide, C. R., 109, 266, 1889. Occurs as a recent formation on bronze coins at Bourbonne-les-Bains (Daubrée).

**Ref.**—[1] Mean deduced by Zepharovich (Ber. Ak. Wien, **68** (1), 120, 1873) from measurements by himself and Klein (Jb. Min., 495, 1871) on Australian crystals; the angles in the prismatic zone show great irregularities (cf. E.S.D., Min. Mitth., 103, 1874); compare also Brögger's results on Chilian crystals, Zs. Kr., **3**, 488, 1879. With Dx., $u = 110$, $b = 001$, etc.

[2] See Zeph., l. c. and ib., **63** (1), 6, 1871, for authorities, etc.; cf. also Miller, Min., p. 618, 1852; Schrauf, Atlas, Tf. XXIV; Gdt., Index, **1**, p. 261, 1886. [3] Bgr., Chili, l. c. [4] N. R., p. 39, 1867; cf. also Bgr., l. c.

A black oxychloride of copper, differing somewhat from atacamite, is described by Domeyko (3d Append., Min. Chili, 1871). It was amorphous, grayish black, without luster. Compact to granular. Fracture even or subconchoidal. It takes a semi-metallic polish under the knife. Composition as obtained by Stuven, deducting impurities, $CuCl_2$ 16·94, CuO 68·67, $H_2O$ 14·39.

*Marcylite* of Shepard, as originally described, was an impure atacamite of a black color; a trial afforded Shepard: Copper 54·30. O and Cl 39 20, H 9·50. G. = 4–4·1. From the south part of the Red River, near the Wachita Mts. (See further under Melaconite.)

TALLINGITE *A. H. Church*, J. Ch. Soc., 18, 77, 213, 1865.

In thin crusts, consisting of irregular aggregations of minute globules, appearing botryoidal under the microscope. Subcrystalline. H. = 3. G. = 3·5 approx. Color bright blue, inclining to green. Streak white. Subtranslucent. Hygroscopic.

A hydrated copper chloride, according to Church. Analysis yielded: Cl 11·33, CuO 66·24. which is explained as Cl 11·33, CuO 53·57, Cu 10·11. $H_2O$ 24·99 = 100, for which Groth writes $Cu_6(OH)_8Cl_2 + 4H_2O$. Another sample contained more water.

Occurs at the Botallack mine, Cornwall. Named after R. Talling, of Lostwithiel, by whom the mineral was collected.

MELANOTHALLITE. Melanotallo *A. Scacchi*, Att. Acc. Napoli, May, 1870.

In thin scales at first black and gradually changing from without to green.

Composition perhaps $CuCl_2.CuO.2H_2O$ = $CuCl_2$ 53 8, CuO 31 8, $H_2O$ 14·4 = 100. Analysis: E. Scacchi, Rend. Acc. Napoli, Dec., 1884, and Zs. Kr., 11, 405, 1886.

| | | |
|---|---|---|
| $CuCl_2$ 58·25 | CuO 31·37 | $H_2O$ (100°) 10·38 = 100 |
| 57·37 | 31·39 | 11·24 = 100 |

Dissolves in water, giving an acid reaction. Found with euchlorine and hydrocyanite at Vesuvius.

ERYTHROCALCITE. Eriocalco *A. Scacchi*. A hydrated copper chloride found in wool-like aggregates of a bright blue color; from the eruption of 1869 at Vesuvius.

It deliquesces on exposure. Composition $CuCl_2$ with an undetermined amount of water; an analysis of the aqueous solution gave: Cu 48·08, Cl 51·92. E. Scacchi, Rend. Acc. Napoli, Dec., 1884, Zs. Kr., 11, 405, 1886.

ATELITE. Atelina *A. Scacchi*, Att. Acc. Napoli, 6, 1873, Contr. Min., II, 22, 1874. Observed as more or less complete pseudomorphs after tenorite, and formed by the action on the latter of fumes of hydrochloric acid; as a result the black color is changed to green. An analysis gave: CuO 45·59, $CuCl_2$ 38·19, $H_2O$ and loss 16·22 = 100. This corresponds to $2CuO.CuCl_2.3H_2O$. Found at Mt. Vesuvius, as a result of the eruption of April, 1872. It is not far from atacamite. Named from ἀτελής, *imperfect*.

**194. DAUBRÉEITE.** Daubreite *I. Domeyko*, C. R., 82, 922, 1876; Min. Chili, p. 297, 1879.

Amorphous; structure compact, earthy, in part fibrous.

H. = 2–2·5. G. = 6·4–6·5. Color yellowish to grayish white. Opaque.

**Comp.**—A hydrated oxychloride of bismuth, perhaps $2Bi_2O_3.BiCl_3.3H_2O$ (Rg.).

**Anal.**—Domeyko, l. c.

| | | | |
|---|---|---|---|
| $Bi_2O_3$ 89·60 | Cl 7·50 | $H_2O$ 3·84(?) | $Fe_2O_3$ 0·72 = 101·66 |

**Pyr.**—In the closed tube gives off acid water, and becomes grayish in color; but on continued heating below fusion turns yellow again. B.B. colors the flame slightly blue; in very thin splinters fuses on the end instantly, the fused part becoming black and compact. Soluble in hydrochloric acid in the cold without residue; the solution has a more or less yellow color.

**Obs.**—Occurs at the Constancia mine, Cerro de Tazna, Bolivia. Named after M. Daubrée, of Paris.

**195. NOCERITE.** Nocerina *A. Scacchi*, Acc. Linc. Trans., 5, 270, 1881. Nocerin.

Hexagonal. In very slender white acicular crystals. Optically negative, uniaxial, Btd[1].

**Comp.**—Perhaps $2(Ca,Mg)F_2.(Ca,Mg)O$, but doubtful.

**Anal.**—E. Fischer and Lederer, Zs. Kr., **10**, 270, 1885.

| F | Al | Mg | Ca | Na | K | O |
|---|---|---|---|---|---|---|
| 37·60 | 4·38 | 17·52 | 26·92 | 2·47 | 0·51 | 11·40 = 100·80 |

**Obs.**—Occurs in volcanic bombs in the tufa of Nocera, near Naples, Italy; it is associated with fluorite, some brown crystals referred to amphibole, and minute crystals in hexagonal prisms, perhaps a variety of microsommite. The exterior of the bombs is covered with mica.

**Ref.**—[1] Bull. Soc. Min., **5**, 142, 1882.

FLUOSIDERITE *A. Scacchi;* E. Fisher, Zs. Kr., **10**, 270, 1885.

In minute crystals forming a granular crust of a bright red color underneath the mica covering of the bombs of Nocera which have yielded the nocerite (see above). Composition unknown; some measurements, but not leading to definite results, have been made by vom Rath, Ber. nied. Ges., Dec. 4, 1882.

PSEUDONOCERINA *A. Scacchi*, Mem. Accad. Napoli, **2**, 1885; Vulcani fluoriferi, p. 69.

In minute, transparent acicular crystals, resembling nocerite and also containing fluorine, but of unknown composition. Fusible B.B. Dissolves in boiling hydrochloric acid with difficulty; with sulphuric acid fluorine is liberated. Found in bombs inclosed in the tufa of Pacognano, near Vico Equense on the south side of the Bay of Naples.

**196. FLUOCERITE.** Neutralt flussspatssyradt Cerium *Berz.*, Afh., **6**, 56, 1818. Neutrales flusssaures Cerer, Flusscerium ceriumfluat, *Germ.* Neutral Fluate of Cerium. Cerium fluatée *Fr.* Flucérine *Beud.*, Tr., **2**, 519, 1832. Fluocerit *Haid.*, Handb., 500, 1845.

Massive.

H. = 4. G. = 5·70 W.; 5·93 Österby, Nd. Luster resinous. Color reddish yellow. Subtranslucent to opaque.

**Comp.**—$R_2OF_4$ or $R_2O_3.4RF_3$, where R = cerium metals chiefly, with some of the yttrium group.

**Anal.**—M. Weibull and Tedin, G. För Förh., **8**, 496, 1886; *b* recalculated on basis of atomic weights: Ce = 141, Di,La = 143, Y, etc. = 97·5.

| | $Ce_2O_3$ | $(La,Di)_2O_3$ | $(Y,Er,Yt)_2O_3$ | F | | $H_2O$ | |
|---|---|---|---|---|---|---|---|
| G. = 5·70 | $\frac{4}{4}$ 46·03 | 36·00 | 3·96 | 19·49 | | 1·78 | Cl,$Al_2O_3$ *tr.*, [$CaCO_3$ 1·50 = 108·76[a] |
| | Ce | La,Di | Y,Er,Yt | F | O | $H_2O$ | |
| | 39·53 | 30·82 | 3·19 | 19·49 | 4·43 | 1·78 | $CaCO_3$ 1·50 = 100·74 |

[a] Deduct O (= F) 8·21 = 100·55

**Pyr., etc.**—In the closed tube yields water, and at a high temperature corrodes the glass; the water contains fluorine, and tinges Brazil-wood paper yellow; the assay changes from yellow to white by heat. B.B. on charcoal infusible, but darkens in color. With soda it is not dissolved, but divides and swells up; the soda is absorbed by the charcoal, and leaves a gray mass on the surface.

**Obs.**—Occurs at Österby in Dalarne, Sweden, in pegmatyte veins with gadolinite, orthite, etc. Cf. remarks under tysonite, p. 166.

## III. Hydrous Chlorides, etc.

---

## A. Hydrous Chlorides.

**197. BISCHOFITE** *Ochsenius* [Die Bildung der Salzlager, Halle, 1877], JB. Ch., pp. 1284, 1285, 1877.

Crystalline-granular and foliated, sometimes fibrous.

H. = 1–2. G. = 1·65. Colorless to white. Luster vitreous to dull.

**Comp.**—$MgCl_2 + 6H_2O$ = Chlorine 35·0, magnesium 11·8, water 53·2 = 100.

**Anal.**—Koenig:

$\frac{2}{2}$ Cl 35·04 Mg 11·86 $H_2O$ [53·10] = 100

Soluble in 0·6 parts of cold water.

**Obs.**—Occurs in layers 2–3 cm. thick in halite, with kieserite and carnallite; the fibers transverse to the layers, at Leopoldshall, Prussia. The assumption of water is said to commence as soon as the layer is exposed to the air. The artificial salt is monoclinic, cf. Rg., Kr. Ch., 264, 1881.

Named after Dr. Gustav Bischof, the German chemist and geologist (1792–1870).

**198. KREMERSITE.** Eisenchlorid mit den Chloralkalien *Kremers*, Pogg., **84**, 79, 1851. Kremersit *Kenng.*, Min., 9, 1853.

Isometric. In octahedrons.

Color ruby-red. Easily soluble.

**Comp.**—$KCl.NH_4Cl.FeCl_3 + H_2O$ = Potassium chloride 24·2, ammonium chloride 17·3, ferric chloride 52·6, water 5·9 = 100; or Chlorine 57·5, potassium 12·7, ammonium 5·8, iron 18·1, water 5·9 = 100.

**Anal.**—Kremers, l. c.:

Cl 55·15 Fe 16·89 K 12·07 $NH_4$ 6·17 Na 0·16 H [9·56] = 100

**Obs.**—From fumaroles at Vesuvius, associated with ferric chloride as a product of sublimation.

Named after the chemist Dr. P. Kremers.

**199. ERYTHROSIDERITE.** Eritrosidero *A. Scacchi,* Contr. Min., II, p. 42, 1874. Rend. Acc. Napoli, Oct., 1872.

Orthorhombic. Axes $\breve{a} : \bar{b} : \dot{c}$ = 0·6911 : 1 : 0·7178 Scacchi.

100 ∧ 110 = *34° 39′, 001 ∧ 101 = 46° 5′, 001 ∧ 011 = 35° 40¼′.

**Forms:** *a* (100, *i*-ī); *d* (102, ½-ī), *e* (101, 1-ī). Angles: *mm‴* = 69° 18′, *dd′* = 54° 53′, *ee′* = 92° 10′, *ad* = 62° 33′, *ae* = 43° 55′.

Crystals somewhat tabular ‖ *a*. Color red, very deliquescent.

**Comp.**—$2KCl.FeCl_3.H_2O$ = Chlorine 53·8, iron 17·0, potassium 23·7, water 5·5 = 100.

**Anal.**—Scacchi, l. c.:

Cl 53·30 Fe 16·81 K 24·21 $H_2O$ 5·68 = 100

**Obs.**—Found at the cone of Vesuvius embedded in the lava of April, 1872, and undoubtedly formed at that time.

Named from ἐρυθρός, *red*, and σίδηρος, *iron*.

**200. DOUGLASITE.** *Ochsenius, Precht*, Ber. Ch. Ges., **13**, 2328, 1881. Eisenchlorürchlorkalium *Germ*.

A salt associated with carnallite at Stassfurt and stated to have the composition $2KCl.FeCl_2.2H_2O$ = Chlorine 48·2, potassium 26·6, iron 19·1, water 6·1 = 100.

The artificial salt is monoclinic with G. = 2·162. Cf. Sbs., Ber. Ak. Wien, **4** (1), 475, 1850, and Rg., Kr. Ch., 273, 1881.

**201. CARNALLITE.** Carnallit *H. Rose*, Pogg., **98**, 161, 1856. Kalium-Magnesiumchlorid *Germ*.

Orthorhombic. Axes $\breve{a} : \bar{b} : \dot{c}$ = 0·59356 : 1 : 0·69062 Hessenberg[1].

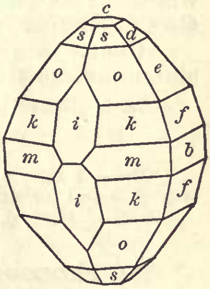
100 ∧ 110 = 30° 41½′, 001 ∧ 101 = 49° 19⅔′, 001 ∧ 011 = 34° 37⅚′.

**Forms**[2]: *b* (010, *i*-ĭ), *c* (001, *O*), *m* (110, *I*), *i* (201, 2-ī), *d* (043, ⁴⁄₃-ī), *e* (021, 2-ĭ), *f* (041, 4-ĭ), *s* (223, ⅔), *o* (111, 1), *k* (221, 2)

*mm‴* = *61° 23′ *ff′* = 140° 12′ *ss′* = 70° 20′ *ss‴* = 39° 59′
*ii′* = 133° 29′ *cs* = 42° 3′ *oo′* = 87° 30′ *oo‴* = 48° 28′
*dd′* = 85° 17′ *co* = *53° 32′ *kk′* = 107° 32′ *kk‴* = 57° 13′
*ee′* = 108° 11½′ *ck* = 69° 43′

Crystals rare, resembling hexagonal pyramids. Commonly massive, granular. No distinct cleavage. Fracture conchoidal. Brittle. H. = 1. G. = 1·60. Luster shining, greasy. Color milk-white, often reddish and with a metallic schiller due to minute enclosed scales of hematite. Transparent to translucent. Strongly phosphorescent. Taste bitter. Deliquescent. Optically +. Double refraction strong. Ax. pl. ‖ *b*. Bx ⊥ (100).

$2E_r$ = 115° 1′, $2E_{bl}$ = 117° 0′ Dx.[3]



Hessenberg.

**Comp.**—$KMgCl_3.6H_2O$ or $KCl.MgCl_2 + 6H_2O$ = Chlorine 38·3, potassium 14·1, magnesium 8·7, water 39·0 = 100 or Potassium chloride 26·8, magnesium chloride 34·2, water 39·0 = 100.

Analyses (5th Ed., p. 118, also Hammerbacher, Inaug. Diss., p. 21, Erlanger, 1874) show the presence of some sodium and calcium chlorides, calcium sulphate, etc. It also sometimes incloses besides iron oxide more or less organic matter. Hammerbacher found thallium in the Stassfurt mineral.

**Pyr., etc.**—B.B. fuses easily. Soluble in water, 100 parts of water at 18·75° C. taking up 64 5 parts; deliquescent.

**Obs.**—Occurs at Stassfurt, where it forms beds in the upper part of the salt formation, alternating with thinner beds of common salt and kieserite, and also mixed with the common salt. Its beds consist of subordinate beds of different colors, reddish, bluish, brown, deep red, sometimes colorless. The red varieties inclose scales of iron oxide and resemble some varieties of oligoclase (sunstone) from Tvedestrand (Groth). Sylvite occurs in the carnallite and may have been formed from it (Tschermak); as may also have been true at Kalusz, Galicia. Also found with salt at Maman in Persia.

Named after von Carnall of the Prussian mines.

**Artif.**—Occurs artificially formed in the salt-pans at Halle.

**Ref.**—[1] On natural crystals, a secondary formation at Stassfurt, Min. Not., **7**, 12, 1866. Rg. (Kr. Ch., 204, 1855) made the artificial crystals hexagonal with *co* = 53° 42′; they were later shown to be orthorhombic, Dx., Ann. Mines, **6**, 593, 1864, and N. R., **46**, 1867. Marignac obtained on artificial crystals: *mm‴* = 61°, *co* = 53° 35′, Ann. Mines, **12**, 3, 1857. The axes of Hbg. are calculated from his measured angle *mm‴* = 61° 23′ and an angle (Rg.) for artif. crystals.

viz.: $oo^{\text{iv}} = 72°\ 40'$, that is $co = 53°\ 40'$. [2] Hbg., l. c., all but *i* observed by Dx. (l.c.) on artificial crystals. [3] On masses from Stassfurt, l. c.

**202. TACHHYDRITE.** Tachhydrit *Rammelsberg*, Pogg., **98**, 261, 1856. Tachyhydrite, Tachydrite.

Rhombohedral. Axis $\dot{c} = 1{\cdot}90$; $rr' = 104°$ Groth[1].

Massive; in roundish masses with easy rhombohedral cleavage, and twin-lamellæ forming planes of parting.

Color wax- to honey-yellow. Transparent to translucent. Very deliquescent on exposure. Optically uniaxial, negative, Dx.[2]

**Comp.**—$CaMg_2Cl_6.12H_2O$ or $CaCl_2.2MgCl_2 + 12H_2O$ = Chlorine 41·1, calcium 7·7, magnesium 9·3, water 41·9 = 100, or Calcium chloride 21·4, magnesium chloride 36·7, water 41·9 = 100.

**Anal.**—Hammerbacher, Inaug. Diss., p. 24, Erlangen, 1874. Also Rg., l. c.; 5th Ed., p. 119.

$\frac{2}{3}$ Cl 40·85 Ca 7·16 Mg 9·97 $H_2O$ 42·50 = 100·48

**Pyr., etc.**—Fuses easily. Very soluble; 100 parts of water at 18·75° C. dissolving 160·3 of the salt.

**Obs.**—From the salt mines of Stassfurt, in thin seams with carnallite and kieserite, in anhydrite.

Named in allusion to its ready deliquescence, from ταχύς, *quick*, and ὕδωρ, *water*.

**Ref.**—[1] Tab. Ueb., 74, 1874. [2] N. R., 20, 1867.

**203. FLUELLITE.** Fluellite *Lévy*, Ann. Phil., **8**, 242, 1824. Fluate of Alumine, Fluorid of Aluminium.

Orthorhombic. Axes $\breve{a} : \bar{b} : \dot{c} = 0{\cdot}7700 : 1 : 1{\cdot}8776$ Miller[1].

$100 \wedge 110 = 37°\ 35\frac{3}{4}'$, $001 \wedge 101 = 67°\ 42'$, $001 \wedge 011 = 61°\ 57\frac{2}{3}'$.

In rhombic pyramids (*r*, 111) with basal plane.

Angles: $rr' = {}^*97°\ 48'$, $rr'' = {}^*144°$, $rr''' = 70°\ 56'$, $cr = 72°$.

Cleavage: *r* indistinct. H. = 3. G. = 2·17. Luster vitreous. Colorless to white. Transparent. Ax. pl. ‖ 100. Bx ⊥ *c*. Ax. angle large, = 100° approx. Groth. Refractive index 1·47.

**Comp.**—A hydrous fluoride of aluminium, $AlF_3 + H_2O$ = Fluorine 56·0, aluminium 26·4, water 17·6 = 100, Groth-Brandl.

**Anal.**—Brandl, Zs. Kr., **7**, 484, 1883.

F 56·25 Al 27·62 Na 0·58 $H_2O$ [15·55] = 100

**Obs.**—A rare mineral found at Stenna-gwyn, Cornwall, in minute crystals on quartz, with wavellite and torbernite.

**Ref.**—[1] Min., p. 607, 1852.

**204. PROSOPITE.** Prosopit *Scheerer*, Pogg., **90**, 315, 1853, **92**, 612, 1854, **101**, 361, 1857.

Monoclinic (or triclinic): Axes: $\grave{a} : \overset{1}{b} : \dot{c} = 1{\cdot}3188 : 1 : 0{\cdot}5950$; $\beta = 85°\ 40' = 001 \wedge 100$ Dx.[1]

$100 \wedge 110 = 52°\ 45'$, $001 \wedge 101 = 23°\ 30\frac{2}{3}'$, $001 \wedge 011 = 30°\ 40\frac{5}{6}'$.

**Forms**[2]: *b* (010, *i-ì*), *m* (110, *I*), *o* (011, 1-*ì*), *t* ($\bar{1}$11, 1), *z* (211, −2-2), *y* (231, −3-$\frac{3}{2}$).

$mm''' = 105°\ 30'$ $tt' = 58°\ 13'$ $bz = {}^*66°\ 59'$ $mz = {}^*45°\ 28'$
$bm = {}^*37°\ 15'$ $zz' = 46°\ 2'$ $by = 38°\ 7'$ $mt = 54°\ 59'$
$oo' = 61°\ 22'$ $yy' = 103°\ 46'$

In embedded crystals; also granular massive. Crystals sometimes tabular ‖ *b*.

Cleavage: *z* distinct. Fracture uneven. Brittle. H. = 4·5. G. = 2·88–2·89. Luster vitreous, weak. Colorless, white, grayish. Transparent to translucent. Optically +. Double refraction strong. Ax. pl. ‖ *b*. Bx nearly ‖ edge *z*/*z*′. Dispersion $\rho > v$. Ax. angles, Dx.:

$2H_{a\,r} = 65°\ 9'$ ∴ $2E_r = 104°\ 14'$ also $2H_{o.r} = 120°\ 56'$ ∴ $2V_r = 63°\ 30'$ $\beta_r = 1{\cdot}500$

$2H_{a.y} = 64° 21' \therefore 2E_y = 102° 50'$ also $2H_{o.y} = 121° 42' \therefore 2V_y = 62° 45'$ $\beta_y = 1{\cdot}502$

$2H_{a.bl} = 60° 35' \therefore 2E_{bl} = 96° 24'$ " $2H_{o.bl} = 124° 38' \therefore 2V_{bl} = 59° 20'$ $\beta_{bl} = 1{\cdot}506$

**Comp.**—A hydrous fluoride of aluminium and calcium, $CaAl_2(F,OH)_8$ or $CaF_2.2Al(F,OH)_3$ Groth-Brandl.

**Anal.**—1, Brandl, Zs. Kr., **7**, 490, 1883. 2, Hillebrand, Bull. **20**, U. S. G. Surv., 64, 1885. An earlier incomplete analysis was made by Scheerer.

| | | F | Al | Ca | Mg | Na | $H_2O$ | O |
|---|---|---|---|---|---|---|---|---|
| 1. Altenberg | | 35·01 | 23·37 | 16·19 | 0·11 | 0·33 | 12·41 | [12·58] = 100 |
| 2. Colorado | G. = 2·880 | $\frac{5}{5}$ 33·18 | 22·02 | 17 28 | 0·17 | 0·48 | 13·46 | [13·41] = 100 |

**Pyr., etc.**—In the glass tube affords water and silicon fluoride. Decomposed by sulphuric acid. The water goes off above 260° C.

**Obs.**—Occurs at the tin mines of Altenberg, in crystals, part of which are a kind of kaolin, and others, according to observations by G. J. Brush (Am. J. Sc., **25**, 411, 1858), cleavable violet fluorite, and others still. fluorite partly kaolinized. Also found at the Schlackenwald tin mines. In cellular pachnolite, derived from the alteration of cryolite, with fluorite and astrophyllite at St. Peter's Dome near Pike's Peak, Colorado.

Named from *προσωπεῖον, a mask,* in allusion to the deceptive character of the mineral.

**Ref.**—[1] Made triclinic by Dx. (N. R., 190, 1867), but as shown by Groth (Zs. Kr., **7**, 489, 1883) the variations in angle lie within the probable errors of observation, and hence it seems better to regard it as monoclinic, at least provisionally. These axes are calculated from the fundamental angles of Dx., the mean of 010 ∧ 110, 0$\bar{1}$0 ∧ 1$\bar{1}$0, also of 010 ∧ 211, 0$\bar{1}$0 ∧ 2$\bar{1}$1, being taken. | 7. | " | | 50·61 | 13·26 | 17·22 | 10·43 | 8·42 = 99·94 |

**Pyr., etc.**—Fuses more easily than cryolite to a clear glass. The massive mineral decrepitates remarkably in the flame of a candle. In powder easily decomposed by sulphuric acid.

**Obs.**—Found with pachnolite on the cryolite of Greenland, as a result of alteration of the latter. First noticed by Dr. Julius Thomsen of Copenhagen, the originator of the cryolite industry, after whom it is named. It differs strikingly from pachnolite in its pearly basal cleavage and its nearly square prisms; and from cryolite in the horizontal striæ of the same and the facility of cleavage. The compact variety referred here by Dr. Hagemann has much of the aspect of chalcedony; it incrusts cryolite or occupies seams or cavities in it, and is covered by the chalky gearksutite; the incrustations are sometimes half an inch or more thick.

Also occurs sparingly with pachnolite and other fluorides at St. Peter's Dome, near Pike's Peak, Colorado.

**Ref.**—[1] Nat. Ber. aus Ungarn, **1**, 162, 1882.

HAGEMANNITE *Shepard*, Am. J. Sc., **42**, 246, 1866. Closely resembles in aspect and condition the compact thomsenolite, but passes sometimes into a yellow, opaque, jaspery variety. It incrusts the cryolite, and also constitutes seams ⅓ to ½ inch thick. It sometimes traverses a drusy ferruginous pachnolite. It is ocher-yellow to wax-yellow in color, rarely faint greenish, dull, or with only a faintly glimmering luster, and looks like an iron flint, or yellow chloropal. H. = 3–3·5. G. = 2·59–2·60. Adheres but feebly to the tongue.

Hagemann obtained in an analysis: F 40·30, Al 12·06, Fe 5 96, Mg 2·30, Ca 11·18, Na 8·45, Si 7·79, $H_2O$ 10·44. G. = 2·83. Decrepitates surprisingly in the flame of a candle.

No probable formula can be deduced. Excluding the Si,Mg,Fe, the composition is that of thomsenolite; it is consequently probably an impure thomsenolite. Cf. Groth, Zs. Kr., **7**, 480, 1883.

## 207. GEARKSUTITE *Hagemann; Dana*, Min., p. 130, 1868. Evigtokite *Flight*, J. Ch. Soc., 43, 140, 1883.

Earthy, kaolin-like in aspect, but consisting of very minute colorless needles, with oblique extinction.

H. = 2. Luster dull. Color white.

**Comp.**—Perhaps $CaF_2.Al(F,OH)_3.H_2O$ = Fluorine 42·9, aluminium 15·1, calcium 22·4, water 15·1, oxygen 4·5 = 100, if F : OH = 2 : 1, Hillebrand.

**Anal.**—1, Hillebrand, Bull. **20**, U. S. G. Surv., 59, 1885. 2, G. Lindström, G. För. Förh., **7**, 687, 1885.

| | F | Al | Ca | Na | K | $H_2O$ | O | |

| 1. Colorado | $\frac{2}{2}$ 42·07 | 15·20 | 22·30 | 0·10 | 0·04 | 15·46 | [4·83] | = 100 |
| 2. Ivigtut | 41·81[a] | 15·37 | 21·02 | 1·06 | 0·23 | 15 03 | 4·82 | Fe 0·30, Mg 0·16, Cl 0·20=100 |

[a] Direct determination 40·55.

Hagemann's analysis (5th Ed., p. 130) is shown by Hillebrand to be incorrect in the determination of fluorine and water; the same author shows that Flight's *evigtokite* is identical with gearksutite. Flight gives: Al 16·23, Ca 22·39, Na 0·43 or $AlF_3$ 49 87, $CaF_2$ 43·66, NaF 0·76, $H_2O$ [5·71] = 100.

**Pyr.**—B.B. fuses easily to a white enamel. Gently heated in the tube gives off neutral water, but more strongly heated attacks the glass. Soluble in acids.

**Obs.**—Occurs sparingly with the Greenland cryolite, and is one of the results of its alteration. The underlying material is compact thomsenolite. Also more abundant with the fluorides, cryolite, pachnolite, etc., of St. Peter's Dome near Pike's Peak, Colorado.

Named from γή, *earth*, and *arksutite*, alluding to its earthy aspect.

## 208. RALSTONITE. *G. J. Brush*, Am. J. Sc., 2, 30, 1871.

Isometric. In octahedrons, also with cubic planes.

Cleavage none. Fracture uneven. Brittle. H. = 4·5. G. = 2·56–2·62. Luster vitreous. Colorless to white, milky, often yellow on the surface. Transparent to translucent. Often shows weak double-refraction, Btd.[1]

**Comp.**—A hydrous fluoride of sodium and aluminium, $(Na_2,Mg)F_2.3Al(F,OH)_3.2H_2O$, Penfield and Harper. If Na : Mg = 1 : 1 and F : OH = 2 : 1, this requires: Fluorine 43·4, aluminium 23·0, magnesium 4·5, sodium 4·4, water 17·9, oxygen 6·8 = 100.

**Anal.**—1, Nordenskiöld, on 0·22 gr., G. För. Förh., **2**, 81, 1874. 2, Brandl, on 0·5 gr., Zs. Kr., **7**, 474, 1883. 3, Penfield, Am. J. Sc., **32**, 380, 1886. 4 Penfield and Harper, ibid.

[a] This, as calculated, includes F 38·13, O 10·69.

Penfield and Harper confirm Nordenskiöld in finding the fluorine insufficient to unite with the bases; they complete analysis 4 by calculating the amount of hydroxyl required, viz. 16·27 (= 8·61 $H_2O$), here F : OH = 2 : 1.

**Pyr., etc.**—In the closed tube whitens, yields water at first, then a copious white sublimate which etches the tube. The water reacts acid. B.B. on charcoal a faint white sublimate. In the forceps whitens, colors the flame yellow, but does not fuse. With cobalt solution gives a deep blue. In salt of phosphorus dissolves completely to a colorless bead in both flames. Soluble with effervescence in a bead of sodium carbonate. Decomposed by sulphuric acid with evolution of hydrofluoric acid.

**Obs.**—Occurs with cryolite and thomsenolite at Ivigtut, Arksuk Fiord, Greenland.

**Ref.**—[1] Bull. Soc. Min., 4, 34, 1881.

**209. YTTROCERITE.** Yttrocerit *Gahn & Berzelius*, Afh., 4, 151, 1814. Yttrocererit *Leonh.*, Handb., 573, 1826. Yttria fluatée *Fr.* Fluate of Cerium and Yttria. Ytterflussspath, Flussyttrocalcit, *Germ.* Yttrocalcit *Glock.*, Syn., 283, 1847.

Massive: crystalline-granular and earthy.

Cleavage: in two directions inclined to each other 71° 30′. Fracture uneven. H. = 4–5. G. = 3·447 Berz.; 3·363 Rg. Luster glistening; vitreous to pearly. Color violet-blue, inclining to gray and white, often white; sometimes reddish brown.

**Comp.**—A fluoride of calcium with the metals of the cerium and yttrium groups. According to Rammelsberg the formula is $2(2RF_3.9CaF_2) + 3H_2O$, with R = Ce(La,Di) : Y(Er) = 1 : 2; further the cerium metals consist one-half of lanthanum and didymium, and the yttrium contains 30 p. c. of erbium.

**Anal.**—1, 2, Rg., Ber. Ch. Ges., 3, 857, 1870. Also earlier, Gahn and Berzelius (l. c. and Schw. J., 16, 241, 1816), 5th Ed., p. 125.

| | | CaO | $Ce_2O_3$ | $Y_2O_3$ | $H_2O$ |
|---|---|---|---|---|---|
| 1. | G. = 3·363 | 47·27 | 9·35 | 14·87 | 2·52 |
| 2. | | 49·32 | 16·14 | | |

**Pyr., etc.**—In the closed tube gives water. B B. on charcoal alone infusible; with gypsum the yttrocerite of Finbo fuses to a bead, not transparent, and that of Broddbo is infusible. With the three fluxes the Finbo mineral behaves like fluorite; the glass is, however, yellow in the oxidizing flame as long as hot, and becomes opaque sooner than the glass given by fluorite. In a pulverized state it dissolves completely in heated hydrochloric acid, forming a yellow solution.

**Obs.**—Occurs sparingly at Finbo and Broddbo, near Falun in Sweden, embedded in quartz, and associated with albite and topaz. Also at Amity, Orange Co., N. Y.; in Mass., probably Worcester Co.; at Mt. Mica, in Paris, Maine.

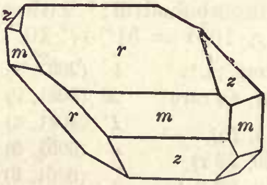
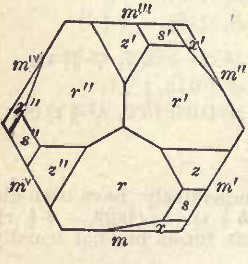


Figs. 1–6, simple forms. 7, Typical right-handed crystal. 8, Left-handed crystal. 9–12, Twins. 13, Distorted crystal. 9, 10, Sbk. 11, Switzerland, Dx. 12, Madagascar, Pfd.

Crystals commonly prismatic, with the *m* faces horizontally striated (f. 11); terminated either by both rhombohedrons (f. 1, 5, 6), or by one only (f. 3). Often in double six-sided pyramids or quartzoids through the equal development of *r* and *z* (f. 2); rarely *r* predominates (f. 4), the form then having a cubic aspect ($rr' = 85° 46'$). Crystals frequently distorted (f. 6, 13), when the correct orientation may be obscure except as shown by the striations on *m*. The faces *s* and $s_,$ also often striated ∥ edge $r/m'$ (*s*), or ∥ edge $r/m^{v}$ ($s_,$), cf. figs. 7, 8, 14; also striations common in other zones, f. 17, 18. Crystals often elongated to acicular forms, and tapering through the oscillatory combination of successive rhombohedrons with the prism. Occasionally twisted or bent. Frequently in radiated masses with a surface of pyramids, or in druses.

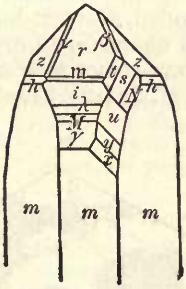
14.



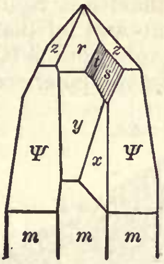
The + rhombohedron (*r*) is usually the predominating form, where *r* and *z* are not equally developed, and its faces often show a higher luster than those of *z*; it can always be recognized by the shape of the etching figures (cf. figs. 26, 27), and also in most cases by pyroelectrical phenomena when these are distinct (see below). As shown by Rose, simple crystals are either right- or left-handed. On a *right-handed* crystal (f. 7), *s*, if present, lies to the right of the *m* face, which is below the plus rhombohedron *r*, and with this belong the plus right trapezohedrons, as *x*, also *u*, *y*, and *t* (f. 15, 16), and minus left trapezohedrons (f. 17), as *ρ*, *τ*, also *a* (left). On a *left-handed* crystal (f. 8), *s* (properly *s*,) lies to the left of the *m* below *r*, and with it (f. 18, 19, 20, the last two twins) the plus left and minus right trapezohedrons, also *a* (right). The right- and left-handed forms (except apparently ξ and ξ,) occur together only in twins. In the absence of trapezohedral planes the striations on *s* (cf. above and f. 16), if distinct, serve to distinguish the planes *r* and *z*, and hence show the right- and left-handed character of the crystals.

Twins[3]: (1) tw. axis ċ (tw. pl. *m*), axes hence parallel, the individuals both right- or both left-handed but unsymmetrical, *r* then parallel to and coinciding with $\underline{z}$, the resulting form, as in fig. 9, mostly penetration-twins, the parts often irregularly united (cf. f. 19, 20), as shown by dull areas (*z*) on the plus rhombohedral face (*r*); otherwise these twins are recognized by pyro-electrical phenomena.

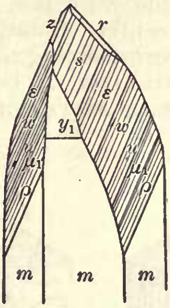
15.



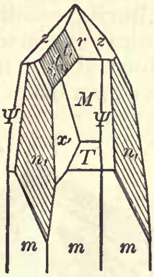
16.



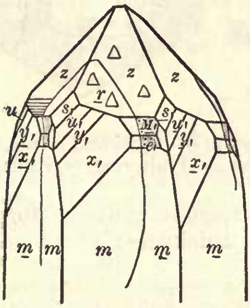
17.



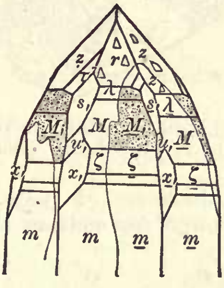
18.



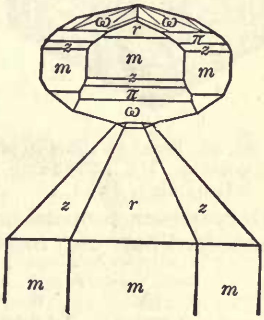
19.



20.



21.



Figs. 15–21, Rath: 15, Dissentis; 16–21, Alexander Co., N. C.

(2) Tw. pl. *a*, sometimes called the *Brazil law*, the individuals respectively right- and left-handed and the twin symmetrical with reference to an *a* face (f. 10), usually as irregular penetration-twins; in these twins *r* and $\underline{r}$, also *z* and $\underline{z}$, coincide. This kind of twinning sometimes gives rise to successive zones of alternate character (as in amethyst); the composition is seen by the simultaneous appearance of planes characterizing both forms (right and left), and in irregular areas on the surface having different physical character; also in the optical behavior of cross-sections (⊥ ċ), as well as by pyro-electrical phenomena. (3) Tw. pl. ξ $(11\bar{2}2)$, contact-twins (f. 11, 12), the axes crossing at an angle of 84° 33′, and a plane *m* coincident in both individuals; the like rhombohedral faces are usually symmetrical, i.e., *r* to $\underline{r}$, etc., but sometimes unsymmetrical, that is, *r* corresponds to *z*, etc. Groupings which simulate twins are common; pseudo-twins, with *s* as the approximate twinning-

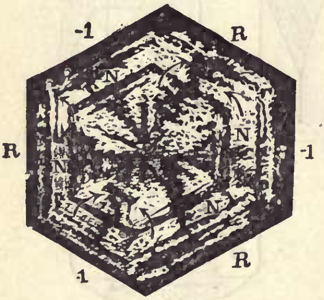
plane, are also produced by the arrangement of crystals in parallel position on the $-\frac{1}{2}R$ faces of calcite.

Massive forms common and in great variety, passing from the coarse or fine granular and crystalline kinds to those which are flint-like or cryptocrystalline. Sometimes mammillary, stalactitic, and in concretionary forms; as sand.

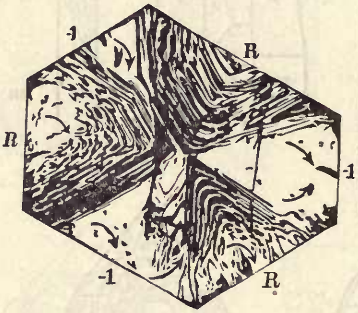
Cleavage: *r*, *z*, difficult and not often observed, also *m*, and sometimes *c*, more difficult; sometimes developed by sudden cooling after being heated; also (Mld.[4]) by the pressure of a sharp point on thin sections, e.g. cut $\parallel \dot{c}$ and $\perp m$. Also a lamellar structure $\parallel r$ and $\parallel z$ as gliding-planes, sometimes developed by secondary means (Judd[4]). Fracture conchoidal to subconchoidal in crystallized forms, uneven to splintery in some massive kinds. Brittle to tough. H = 7. G. = 2·653, 2·654 in crystals, Beud.; 2·660 cryst., Herkimer, Pfd.; cryptocrystalline forms somewhat lower (to 2·60) if pure, but impure massive forms (e.g. jasper) higher. Luster vitreous, sometimes greasy; splendent to nearly dull. Colorless when pure; often various shades of yellow, red, brown, green, blue, black. Streak white, of pure varieties; if impure, often the same as the color, but much paler. Transparent to opaque.

Optically +. Double refraction weak. Polarization circular; axial figure hence having a colored center. Rotation sometimes right-handed, also left-handed, the optical character corresponding to right- and left-handed character of crystals, as defined above; in twins (law 2) both right and left forms sometimes united, sections then often showing Airy's spirals in the polariscope; cf. figs. 23, 24, also 25.

23.



24.



25.

Figs. 23, 24, Basal sections in polarized light, showing interpenetration of right- and left-handed portions, Dx. 25, Same, showing also secondary lamellæ (at *a*, *b*), alternately right- and left-handed, Judd.

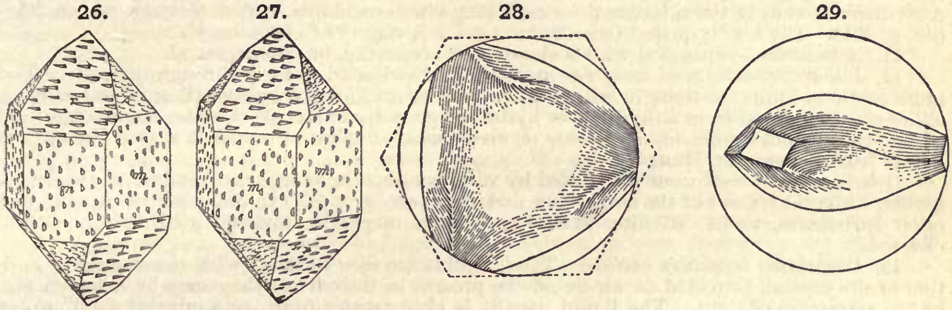
Rotatory power proportional to thickness of plate. Refractive indices[5] for the Fraunhofer lines; also rotatory power[6] for sections of 1mm. thickness:

| | A | B | C | D | E | F | G |
|---|---|---|---|---|---|---|---|
| $\omega$ = | 1·53913 | 1·54090 | 1·54181 | 1·54418 | 1·54711 | 1·54965 | 1·55425 |
| $\epsilon$ = | 1·54805 | 1·54990 | 1·55085 | 1·55328 | 1·55631 | 1·55894 | 1·56365 |
| $a$ | 12°·67 | 15°·75 | 17°·32 | 21°·71 | 27°·54 | 32°·77 | 42°·60 |

For $D_2$ $a$ = 21°·684, for $D_1$ $a$ = 21°·736.

Pyro-electric[7]; also electric by pressure or piezo-electric. By change of temperature a simple crystal is divided into + and − electrical zones parallel to the alternate prismatic edges; in right-handed crystals the right edges below *r*, and in left-handed the corresponding left edges (f. 7, 8), become *negative* on cooling, the alternate edges positive. In twins (1) two adjacent edges may have the same character; in twins (2, Brazil law) all the prismatic edges may have the same sign. Cross-sections $\perp \dot{c}$ are divided into sectors, and the irregular penetration is well exhibited by this method. A non-conductor for electricity, acting, in the form of fine threads, as an insulator in a remarkable degree even in a moist atmosphere. Comparable as a conductor, in the direction of the vertical axis, to glass at high temperatures, but not conducting normal to this direction[8].

Etching figures[11], developed by the action of hydrofluoric acid or alkaline carbonates, exhibit the right- and left-hand character of the crystals (Leydolt, Penfield, Molengraaff) as shown in figs. 26, 27. A sphere from a simple right-handed crystal subjected by Penfield to the action of acid was attacked rapidly in the direction of the vertical axis, but not at all at the + extremities of the axes. Cf. figs. 28, 29.



Figs. 26–29, Crystals etched by hydrofluoric acid, Penfield: 26, right-handed, 27, left-handed, crystal. 28, 29, sphere cut from simple right-handed crystal after being etched by acid for 7 weeks: 28, basal view; 29, front view; circle shows original form of sphere, dotted hexagon the position of axes.

**Comp.**—Silica, or silicon dioxide, $SiO_2$ = Oxygen 53·3, silicon 46·7 = 100.

In massive varieties often mixed with a little opal-silica. Impure varieties contain iron oxide, calcium carbonate, clay, sand, and various minerals as inclusions.

**Var.**—1. PHENOCRYSTALLINE: Crystallized, vitreous in luster.

2. CRYPTOCRYSTALLINE: Flint-like, massive.

The first division includes all ordinary vitreous quartz, whether having crystalline faces or not. The varieties under the second are in general acted upon somewhat more by attrition, and by chemical agents, as hydrofluoric acid, than those of the first. In all kinds made up of layers, as agate, successive layers are unequally eroded.

### A. PHENOCRYSTALLINE OR VITREOUS VARIETIES.

1. *Ordinary Crystallized; Rock Crystal.*—Colorless quartz, or nearly so, whether in distinct crystals or not. Ordinary as above described. Here belong the Bristol diamonds, Lake George diamonds, Brazilian pebbles, etc. Some variations from the common type are: (*a*) cavernous crystals, having deep cavities parallel to the faces—occasioned by the interference of impurities during their formation; (*b*) cap-quartz (Kappen-quarz *Germ.*), made up of separable layers or caps, due to the deposit of a little clayey material at intervals in the progress of the crystal; (*c*) drusy quartz, a crust of small or minute quartz crystals; (*d*) radiated quartz, often separable into radiated parts having pyramidal terminations; (*e*) fibrous (Faserkiesel *Germ.*), rarely delicately so, as a kind from Griqualand West, South Africa, altered from crocidolite (see *cat's-eye* below, also crocidolite p. 400).

2. *Asteriated; Star-quartz* (Stern-quarz *Germ.*).—Containing within the crystal whitish or colored radiations along the diametral planes. Occasionally exhibits asterism somewhat like that of the asteriated sapphire.

3. *Amethystine; Amethyst, Aμέθυστον, Theophr.*, etc.—Clear purple, or bluish violet. The color has been supposed to be due to manganese.

4. *Rose.*—Rose-red or pink, but becoming paler on exposure. Common massive, and then usually much cracked. Luster sometimes a little greasy. Fuchs states that the color is due to titanium; he found 1 to 1½ p. c. in specimens from Rabenstein, near Bodenmais. It may come in part from manganese.

5. *Yellow; False Topaz* or *Citrine.*—Yellow and pellucid, or nearly so; resembling somewhat yellow topaz, but very different in crystallization and in absence of cleavage.

6. *Smoky; Cairngorm Stone.* Mormorion *Plin.*, **37**, 63; Morion. (Rauch-quarz *Germ.*)—Smoky-yellow to smoky-brown, and often transparent; but varying to brownish black, and then nearly opaque in thick crystals. The color is probably due to some organic carbon-nitrogen compound (Forster). Called *cairngorms* from the locality at Cairngorm, S. W. of Banff, in Scotland. The name *morion* is given to some dark colored, nearly black, varieties.

7. *Milky.*—Milk-white and nearly opaque. Luster often greasy, and then called *greasy* quartz.

8. *Siderite*, or *Sapphire-quartz.*—Of indigo or Berlin-blue color; a variety occurring in an impure limestone at Golling in Salzburg.

9. *Sagenitic.*—Containing within acicular crystals of rutile (*a*), often in reticulated net-like forms; the mineral called from such specimens *sagenite* (fr. *σαγήνη, a net*) by de Saussure (see RUTILE).

Other included minerals in acicular forms are: (*b*) black tourmaline; (*c*) göthite; (*d*) stibnite; (*e*) asbestus; (*f*) actinolite; (*g*) hornblende; (*h*) epidote.

*Cat's-Eye* (Katzenauge *Germ.*, Œil de Chat *Fr.*)—Exhibiting opalescence, but without prismatic colors, especially when cut *en cabochon*, an effect sometimes due to fibers of asbestus. Also finely present in the siliceous pseudomorphs, after crocidolite, called *tiger-eye* (see crocidolite, p. 401). The highly-prized Oriental cat's-eye is a variety of chrysoberyl.

11. *Aventurine.*—Spangled with scales of mica, hematite, or other mineral.

12. *Impure from the presence of distinct minerals* distributed densely through the mass. The more common kinds are those in which the impurities are: (*a*) *ferruginous* (Eisenkiesel *Germ.*), either red or yellow, from anhydrous or hydrous iron sesquioxide; (*b*) *chloritic*, from some kind of chlorite; (*c*) *actinolitic;* (*d*) *micaceous;* (*e*) *arenaceous*, or sand. Sinopel is a red ferruginous quartz from Schemnitz, Hungary.

Quartz crystals also occur penetrated by various minerals, as topaz, corundum, chrysoberyl, garnet, different species of the amphibole and pyroxene groups, cyanite, zeolites, calcite, and other carbonates, rutile, stibnite, hematite, göthite, magnetite, fluorite, gold, silver, anthracite, etc.

13. *Containing liquids in cavities.* These liquids are seen to move with the change of position of the crystal, provided an air-bubble be present in the cavity; they may be detected also by the refraction of light. The liquid usually is either water (pure, or a mineral solution), or some petroleum-like or other compound. Quartz, especially smoky quartz, also often contains inclusions of both liquid and gaseous carbon dioxide. The water-cavities also occasionally contain minute cubes of sodium chloride. Cf. Hartley, Hawes[12]. Wright has shown the presence of the gases $CO_2$, N, $H_2S$, $SO_2$, $H_3N$ and F in the smoky quartz of Branchville, Conn.

### B. CRYPTOCRYSTALLINE VARIETIES.

1. *Chalcedony.* Murrhina *Plin.*, **37**, 7. *Ιασπις* pt. *Theophr.* Iaspis pt. *Plin.*, **37**, 37. Murrhina, *Germ.* Chalcedonius, *Agric.*, 466, 1546. Chalcedon, Achates vix pellucida, nebulosa, colore griseo mixta, *Wall.*, 83, 1747. Chalcedon *Germ.* Calcédoine *Fr.*—Having the luster nearly of wax, and either transparent or translucent. G. = 2·6–2·64. Color white, grayish, pale brown to dark brown, black; tendon-color common; sometimes delicate blue. Also of other shades, and then having other names. Often mammillary, botryoidal, stalactitic, and occurring lining or filling cavities in rocks. It often contains some disseminated opal-silica. The name *Enhydros* is given to nodules of chalcedony containing water, sometimes in large amount.

Embraced under the general name chalcedony is the crystalline form of silica which forms concretionary masses with radial-fibrous and concentric structure, and which, as shown by Rosenbusch (Mikr. Phys. Min., 345, 1882), is optically *negative*, unlike true quartz. It has $n_r$ = 1·537; G. = 2·59–2·64. Often in spherulites, showing the spherulitic interference-figure. Becker proposes to distinguish it under the name *chalcedonite* (U. S. G. Surv., Mon., **13**, 390, 1888). Cf. *lussatite* of Mallard, p. 197, which has a like structure, but is optically + and has the specific gravity and refractive index of opal.

2. *Carnelian.* *Σάρδιον* *Theophr.* Sarda *Plin.*, **37**, 23, id. = *Germ.* Carneol, *Agric.*, 468, 1546. Carneol, Agates fere pellucida, colore rubescente, *Wall.*, 82, 1747. Sard. Cornaline Fr.—A clear red chalcedony, pale to deep in shade; also brownish red to brown, the latter kind (Sardoine *Fr.*) reddish brown by transmitted light.

3. *Chrysoprase* (not Chrysoprasus *antiq.*). An apple-green chalcedony, the color due to the presence of nickel oxide. Klaproth found in that of Silesia 1·0 p. c. NiO; and Rammelsberg, in the same, 0·41 p. c. NiO.

4. *Prase.*—Translucent and dull leek-green; so named from *πράσον, a leek.* Always regarded as a stone of little value. The name is also given to crystalline quartz of the same color. "Vilioris est turbæ Prasius" says Pliny.

5. *Plasma.* Iaspis pt. *Plin.*, **37**, 37.—Rather bright green to leek-green, and also sometimes nearly emerald-green, and subtranslucent or feebly translucent; sometimes dotted with white.

*Heliotrope*, or *Blood-stone*, is the same stone essentially, with small spots of red jasper, looking like drops of blood.

The *Iaspis*, or jasper of the ancients, was a semitransparent or translucent stone, and included in Pliny's time all bright-colored chalcedony excepting the carnelian (sard). He gives special prominence to sky-blue and green, and mentions also a shade of purple (the color of the best, he says), a rose-color, the color of the morning sky in autumn, sea-green, terebenthine color (yellow like turpentine, as interpreted by King), smoke-color (his capnias), etc.; but in general there is a tinge of blue, whatever the shade. The green kinds may have been chrysoprase or plasma; or perhaps a variety of jade, a stone known in Europe since the Stone age.

The green, with a line running through it (Monogrammos), may have been plasma, or jade, with a narrow seam of white quartz.

Pliny's *Prasius*, spotted with red, was our heliotrope; his *Heliotrope* (**37**. 60) was a leek-green stone (prase or plasma) veined with blood-red (jasper); and the jasper was so abundant a part as to give a general red reflection to the whole when it was put in water in the face of the sun, whence the name from ἥλιος, *sun*, and *τρέπειν*, *to turn*.

6. *Agate*. 'Αχάτης [fr. Sicily] *Theophr*. Achates pt. *Plin*., **37**, 54.—Onyx pt. *Plin*., ib., 24.—A variegated chalcedony. The colors are either (*a*) banded; or (*b*) in clouds; or (*c*) due to visible impurities.

(*a*) *Banded*. The bands are delicate parallel lines, of white, tendon-like, wax-like, pale and dark brown, and black colors, and sometimes bluish and other shades. They follow courses, sometimes straight, more often waving or zigzag, and occasionally concentric circular, as in the eye-agate (*Leucophthalmus* Plin., **37**, 62, and *Triophthalmus* ib., 71). The fine translucent agates graduate into coarse and opaque kinds. The bands are the edges of layers of deposition, the agate having been formed by a deposit of silica from solutions intermittently supplied, in irregular cavities in rocks, and deriving their concentric waving courses from the irregularities of the walls of the cavity. As the cavity cannot contain enough of the solution to fill it with silica, an open hole has been supposed to be retained on one side to permit the continued supply; but it is more probable that it passes through the outer layers by osmosis, the denser solution outside thus supplying silica as fast as it is deposited within. The colors are due to traces of organic matter, or of oxides of iron, manganese, or titanium, and largely to differences in rate of deposition. The layers differ in porosity, and therefore in the rate at which they are etched by hydrofluoric acid; and consequently the etching process brings out the different layers, and makes engravings that will print exact pictures of the agate. Owing also to the unequal porosity, agates may be varied in color by artificial means, and this is done now to a large extent with the agates cut for ornament.

(*b*) *Irregularly* clouded. The colors various, as in banded agate.

A whitish clouded variety is probably the *Leucachates* Plin. (fr. λευκός, *white*); a wax-colored, his *Cerachates* (fr. *cera*, *wax*), a name that may have been applied also to ordinary wax-colored chalcedony, as the stone was one in little repute; (*c*) a reddish, his *Sardachates*, or carnelian-agate. The last probably included also banded kinds. *Hemachates* (fr. *αἷμα*, *blood*) was probably a true light-colored agate, blotched with red jasper, "blushing with spots of blood," as says Solinus (King, p. 207), of which there are very beautiful kinds, and not simple red jasper. *Iaspachates* must have been an agate in which bluish and greenish shades (Iaspis) predominated. These names are given by Pliny without accompanying descriptions. *Ruin-agate* or *Fortification-agate* is a variety with light to dark brown shades, showing, when polished, curious markings well described by the name.

(*c*) *Colors due to visible impurities*. (*a*) *Moss-agate*, or *Mocha-stone*, filled with brown moss-like or dendritic forms, as of manganese oxide, distributed through the mass. (*b*) *Dendritic Agate*, containing brown or black dendritic markings. These two are the *Dendrachates* Plin. (fr. *δένδρον*, *a tree*).

There is also *Agatized wood:* wood petrified with clouded agate.

7. *Onyx*. *'Ονυχιον* *Theophr*. Onyx pt. [rest agate, or stalagmite, p. 268] *Plin*., **37**, 24. Onice *Ital*.—Like agate in consisting of layers of different colors, but the layers are in even planes, and the banding therefore straight, and hence its use for cameos, the head being cut in one color, and another serving for the background. The colors of the best are perfectly well defined, and either white and black, or white, brown, and black alternate; also white and red. Onicolo *Ital*. (dimin.) is a name given to a kind of onyx in which a thin layer of white over black gives a bluish tinge.

8. *Sardonyx* Plin., **37**, 23.—Like onyx in structure, but includes layers of carnelian (sard) along with others of white or whitish, and brown, and sometimes black colors.

9. *Agate-Jasper*—An agate consisting of jasper with veinings and cloudings of chalcedony.

10. *Siliceous sinter*.—Irregularly cellular quartz, formed by deposition from waters containing silica or soluble silicates in solution. See also under opal, p. 195.

11. *Flint*. Silex pt. *Plin*., Feuerstein *Germ*.—Somewhat allied to chalcedony, but more opaque, and of dull colors, usually gray, smoky-brown, and brownish black. The exterior is often whitish, from mixture with lime or chalk, in which it is embedded. Luster barely glistening, subvitreous. Breaks with a deeply conchoidal fracture, and a sharp cutting edge. The flint of the chalk formation consists largely of the remains of diatoms, sponges, and other marine productions. The silica of flint, according to Fuchs, is partly soluble silica. There is usually a small amount of alumina and iron sesquioxide, with some water. The coloring matter of the common kinds is mostly carbonaceous matter. Flint implements play an important part among the relics of early man.

12. *Hornstone*. Silex pt., *Plin*. (Hornstein *Germ*.)—Resembles flint, but more brittle, the fracture more splintery. *Chert* is a term often applied to hornstone, and to any impure flinty rock, including the jaspers.

13. *Basanite; Lydian Stone*, or *Touchstone*. Lapis Lydius *Plin*., **33**, 43? Basanites id., **36**, 11, Lydite.—A velvet-black siliceous stone or flinty jasper, used on account of its hardness and black color for trying the purity of the precious metals. The color left on the stone after rubbing the metal across it indicates to the experienced eye the amount of alloy. It is not splintery like hornstone. It passes into a compact, fissile, siliceous, or flinty rock, of grayish and

other colors, called siliceous slate, and also *Phthanyte;* and then resembles ordinary jasper of grayish and other shades, especially the banded jaspers.

14. *Jasper.*—Impure opaque colored quartz. (*a*) *Red* (Hæmatitis *Plin.*, **37**, c. 60, not his Hæmatites), iron sesquioxide being the coloring matter. (*b*) *Brownish*, or *ocher yellow*, colored by hydrous iron sesquioxide, and becoming red when so heated as to drive off the water. (*c*) Dark green and brownish green. (*d*) Grayish blue. (*e*) Blackish or brownish black. (*f*) *Striped* or *riband jasper* (Bandjaspis *Germ.*), having the colors in broad stripes. (*g*) *Egyptian jasper*, in nodules which are zoned in brown and yellowish colors. (*h*) Jasponyx. (*i*) Jasperized wood.

*Porcelain jasper* is nothing but baked clay, and differs from true jasper in being B.B. fusible on the edges. *Red porphyry*, or its base, resembles jasper, but is also fusible on the edges, being usually an impure feldspar.

C. Besides the above there are also:

1. *Granular Quartz, Quartz-rock*, or *Quartzyte.*—A rock consisting of quartz grains very firmly compacted; the grains often hardly distinct. 2. *Quartzose Sandstone.* 3. *Quartz-conglomerate.* A rock made of pebbles of quartz with sand. The pebbles sometimes are jasper and chalcedony, and make a beautiful stone when polished. 4. *Itacolumyte*, or *Flexible Sandstone.* A friable sand-rock, consisting mainly of quartz-sand, but containing a little mica, and possessing a degree of flexibility when in thin laminæ. 5. *Buhrstone*, or Burrstone. A cellular, flinty rock, having the nature in part of coarse chalcedony.

6. *Pseudomorphous Quartz.*—Quartz appears also under the forms of many of the mineral species, which it has taken through either the alteration or replacement of crystals of those species. The most common quartz pseudomorphs are those of calcite, barite, fluorite, and siderite. (*a*) *Tabular quartz* consists of intersecting plates of quartz, and is probably a result of the quartz being deposited among intersecting plates of other minerals, as barite. (*b*) *Haytorite* of C. Tripe (Phil. Mag., **1**, 40, 1827) is a pseudomorph after datolite. (*c*) *Babel-quartz* is quartz which has, on the under surface, impressions of cubes of fluorite, arising from its having been deposited over the crystals; from Beer-Alston, Devonshire. (*d*) *Silicified shells* are proper pseudomorphs in quartz; they occur through many rock strata, including limestones. (*e*) *Silicified wood* is quartz pseudomorph after wood. The texture of the original wood is usually well retained, it having been formed by the deposit of silica from its solution in the cells of the wood, and finally taking the place of the walls of the cells as the wood itself disappeared.

*Beekite* (Beckite *Dufr.*) is a chalcedonic chert formed by the replacement of limestone fragments in the New Red conglomerate of South Devon, England; it often takes the form of calcareous shells or other fossils. Named after Dr. Beek, Dean of Bristol. See Hughes for occurrence, literature, etc., Min. Mag., **8**, 265, 1889.

**Pyr., etc.**—B.B. unaltered; with borax dissolves slowly to a clear glass; with soda dissolves with effervescence; unacted upon by salt of phosphorus. Insoluble in hydrochloric acid, and only slightly acted upon by solutions of fixed caustic alkalies, the cryptocrystalline varieties to the greater extent. Soluble only in hydrofluoric acid. When fused and cooled it becomes amorphous silica, having G. = 2·2.

**Obs.**—Quartz occurs as one of the essential constituents of granite, syenite, gneiss, mica schist, and many related rocks; as the principal constituent of quartz-rock and many sandstones; as an unessential ingredient in some trachyte (liparyte), porphyry, etc.; as the veinstone in various rocks, and for a large part of mineral veins; as a foreign mineral in the cavities of basalt, and related rocks, some limestones, etc., making geodes of crystals, or of chalcedony, agate, carnelian, etc.; as embedded nodules or masses in various limestones, constituting the flint of the chalk formation, the hornstone of other limestones—these nodules sometimes becoming continuous layers; as masses of jasper occasionally in limestone. It is the principal material of the pebbles of gravel-beds, and of the sands of the sea-shore, and sand-beds everywhere.

In graphic granite (*pegmatyte*) the quartz is arranged in parallel position in feldspar. The quartz grains in a fragmental sandstone are often found to have undergone a secondary growth by the deposition of crystallized silica with like orientation to the original nucleus. Cf. Sorby, Q. J. G. Soc., **36**, 1880, Pres. Address, p. 62; Irving, Am. J. Sc., **25**, 401, 1883.

Quartz crystals occasionally occur of enormous size. A group in the museum of the university at Naples weighs nearly half a ton. A crystal belonging to Sig. Rafelli, of Milan, measures 3¼ ft. in length and 5½ in circumference, and its weight is estimated at 870 lbs.; another in Paris is 3 ft. in diameter and weighs 8 cwt. About a century since a drusy cavity was opened at Zinken, which afforded 1,000 cwt. of rock crystal, and at that early period brought $300,000. One crystal weighed 800 lbs. A single cavity in a vein of quartz near the Tiefen Glacier, in Switzerland, discovered in 1867, afforded smoky quartz crystals weighing in the aggregate about 20,000 pounds; a considerable number of the single crystals having a weight of 200 to 250 pounds, or even more. A group from Moose Mountain, New Hampshire, at Dartmouth College, weighs 147½ lbs., and contains 48 crystals; four of them are from 5 to 5½ inches in diameter, ten from 4 to 4¼ inches. A crystal from Waterbury, Vt., 2 ft. long and 18 inches through, weighs 175 lbs.

Switzerland, Dauphiné, Piedmont, the Carrara quarries, and numerous other foreign localities, afford fine specimens of rock crystal; also Japan, whence the beautiful crystal spheres, in rare cases up to 6 inches in diameter. *Smoky quartz* crystals of great beauty, and often highly complex in form, occur at many points in the central Alps, also at Cairngorm, Scotland. The most beautiful amethysts are brought from India, Ceylon, and Persia, also from Brazil; inferior specimens occur in Transylvania, in large crystalline groups; in the vicinity of Cork, and on Achill Is., Co. Mayo, Ireland. The *false topaz* is met with in Brazil. *Rose quartz* occurs in a vein of manganese, traversing the granite of Rabenstein, near Zwiesel in Bavaria *Prase* is found in the iron mines of Breitenbrunn, near Schwarzenberg in Saxony; and in Brittany, near Nantes and Rennes. The amygdaloids of Iceland and the Färöer Islands afford magnificent specimens of *chalcedony;* also Hüttenberg and Leoben in Carinthia, etc. A smalt-blue variety, in cubical crystals (pseudomorphs of fluorite), occurs at Tresz'yan in Transylvania. The finest *carnelians* and *agates* are found in Arabia, India, Brazil, Surinam, also formerly at Oberstein and Saxony. Scotland affords smaller but handsome specimens (Scotch pebbles). *Chrysoprase*, at Kosemütz in Silesia. *Aventurine quartz*, at Cape de Gata in Spain. *Cat's-eye*, in Ceylon, the coast of Malabar, and also in the Harz and Bavaria. *Plasma*, in India and China, whence it is usually brought in the form of beads. *Heliotrope*, in Bucharia, Tartary, Siberia, and the island of Rum in the Hebrides. *Float stone*, in the chalk formation of Menil Montant, near Paris, and in some of the Cornish mines. The banks of the Nile afford the Egyptian jasper; the striped jasper is met with in Siberia, Saxony, and Devonshire. A *yellow jasper* is found at Vourla, bay of Smyrna, associated with opal, chrysoprase, and hornstone. The plains of Argos are strewn with pebbles of *red jasper*.

In New York, quartz crystals are abundant in Herkimer Co., at Middleville, Little Falls, Salisbury, and Newport, loose in cavities in the Calciferous sand-rock, or embedded in loose earth, and sometimes, according to Beck, in powdered anthracite. Fine quartzoids, at the beds of hematite in Fowler, Herman, and Edwards, St. Lawrence Co., also at Antwerp, Jefferson Co. In Gouverneur, crystals, with tourmaline, etc., in limestone, which have rounded angles as if they had been partially fused. On the banks of Laidlaw lake, Rossie, large implanted crystals. At Palatine, Montgomery Co., crystals, having one end terminated with the usual pyramid, while the other is rounded and smooth. At Ellenville lead mine, Ulster Co., in fine groups. At Diamond island and Diamond Point, Lake George, quartz crystals, as in Herkimer Co. In Mass., crystals with unusual modifications, sparingly at the Somerville syenite quarry. Pelham and Chesterfield, Mass., Paris and Perry, Me., Benton, N. H., Sharon, Vt., and Meadow Mount, Md., are other localities of quartz crystals. At Chesterfield, Mass., small unpolished rhombohedrons, in granite. At Paris, Me., handsome crystals of brown or smoky quartz. In large crystals, often perfect and weighing several pounds, at Minnesota mine, Lake Superior, occasionally enveloped in metallic copper, as if cast around the crystals. Drusy quartz, of brown, apple-green and other tints, at Newfane, Vt. Beautiful colorless crystals occur at Hot Springs, Arkansas. Alexander Co., N. C., has afforded great numbers of highly complex crystals, with rare modifications. Cf. Rath, l. c., Hidden, Am. J. Sc., 1881, 1883. Fine crystals of smoky quartz come from the granite of the Pike's Peak region, Colorado. Geodes of quartz crystals, also enclosing calcite, sphalerite, etc., are common in the Keokuk limestone of the west. For other localities, see the catalogue of localities in the latter part of this volume.

*Rose quartz*, at Albany, and Paris, Me., Acworth, N. H., Williamsburg, Mass., Southbury, Conn., and Port Henry, Essex Co., N. Y.; *smoky quartz*, at Goshen, Mass., Richmond Co., N.Y., etc.; *amethyst*, in trap, at Keweenaw Point, Pic bay, and Gargontwa, on Lake Superior; with fossilized wood at Specimen Mt., Yellowstone Park; at Bristol, Rhode Island, and sparingly throughout the trap region of Massachusetts and Connecticut; in Surry, New Hampshire; in Pennsylvania, in East Bradford, Aston, Chester, and Providence (one fine crystal over 7 lbs. in weight), in Chester Co.; very handsome at the Prince vein, Lake Superior, but now hardly obtainable, as the mine is not worked; also very large fine crystals, near Greensboro, N. C. Crystallized green quartz, in talc, at Providence, Delaware Co., Penn.; at Ellenville, N. Y., with chlorite. Chalcedony and agates of moderate beauty, in the same trap region; more abundantly about Lake Superior, the Mississippi, and the streams to the west; at Natural Bridge, Jefferson Co., N. Y.; about the Willamette, Columbia, and other rivers in Oregon; abundant and beautiful on N. W. shore of Lake Superior. Belmont's lead mine, St. Lawrence Co., N. Y., has afforded good chalcedony and chrysoprase, associated with calcite. Red jasper is found on Sugar Loaf Mt., Maine; in pebbles on the banks of the Hudson at Troy; yellow, with chalcedony, at Chester, Mass.; red and yellow, near Murphy's, Calaveras Co., Cal. Heliotrope occupies veins in slate at Blooming Grove, Orange Co., N. Y.

Smoky quartz in large crystals, some over 100 lbs., have been found on Paradise R., Nova Scotia.

Agatized and jasperized wood of great beauty and variety of color is obtained from the petrified forest called Chalcedony Park, near Carrizo, Apache Co., Arizona; also from the Yellowstone Park; near Florissant and elsewhere in Colorado; Amethyst Mt., Utah; Napa Co., California. Moss agates from Humboldt Co., Nevada, and many other points. On the occurrence of the ornamental varieties of quartz, see Kunz, Gems and Precious Stones of N. America, 1890.

The word quartz is of German provincial origin. Agate is from the name of the river Achates, in Sicily, whence specimens were brought, as stated by Theophrastus.

**Alt.**—Pseudomorphs of pyrite, cassiterite, magnetite, hematite, voltzite, after quartz, have been described. Quartz pseudomorphs after fluorite, barite, and other species are not uncommon.

**Artif.**—Repeatedly produced, both in well-formed crystals and in chalcedonic varieties; thus (Sénarmont) from gelatinous silica in a closed tube with excess of water at a high temperature; also (Daubrée) by the prolonged action of water vapor upon glass under pressure; again (Hautefeuille) by fusing a mixture of alkaline phosphates and fluorides with silica and alumina, orthoclase was obtained at the same time. By the fusion of silica and lithium chloride at a low red heat quartz crystals were obtained (Hautefeuille and Margottet); at a bright red, crystals of tridymite. Cf. Fouqué-Lévy, Synth. Min., 81, 1882; Bourgeois, Reprod. Min., 79, 1884.

**Ref.**—[1] Preisschrift, p. 61, 1825; cf. Kk. Min. Russl., 8, 129, 1878; Dbr. obtained *rz* = 46° 16′ 4″ 8, Pogg., **103**, 107, 1858.

On the crystallization of quartz see: Rose, Abh. Ak. Berlin, 217–274, 1844, a monograph of the first importance; he gives also the earlier bibliography (Weiss, Haid., Wackernagel, etc.), Dx , Mem. Ac. Sc., **15**, 404, 1858, a second equally important memoir, an abstract in Ann. Ch. Phys., **45**, 129, 1855; also later Min., **1**, 7, 1862. Sella, Ac. Sc. Torino, **17**, 1858 (Min. Sarda). E. COTTERITE *Harkness*, Min. Mag., **2**, 82, 1878. A variety of quartz, having a "peculiar metallic pearly luster," and forming a coating on ordinary quartz crystals, from Rockforest, Ireland.

### 211. TRIDYMITE. *G. vom Rath*, Pogg., **135**, 437, 1868.

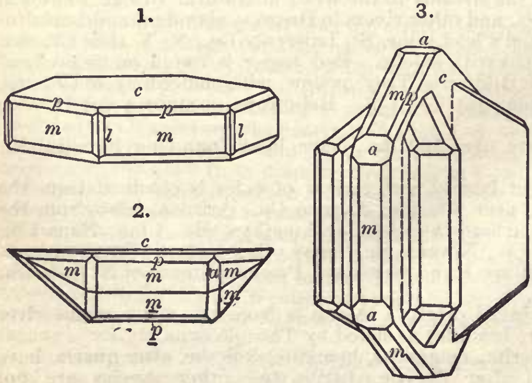
Hexagonal or pseudo-hexagonal. Axis $\dot{c} = 1{\cdot}65304$; $0001 \wedge 10\bar{1}1 = 62° 21'$ Rath[1].

**Forms**[1]: *c* (0001, *O*), *m* ($10\bar{1}0$, *I*), *a* ($11\bar{2}0$, *i*-2), *l* ($45\bar{9}0$, *i*-$\frac{9}{4}$), *i* ($32\bar{5}0$, *i*-$\frac{5}{3}$), *o* ($10\bar{1}3$, $\frac{1}{3}$)[2], *p* ($10\bar{1}1$, 1). Also *q* ($10\bar{1}6$, $\frac{1}{6}$), and *r* ($30\bar{3}4$, $\frac{3}{4}$) as tw. planes.

Angles: *ml* = 10° 53½′, *mi* = 13° 54′, *mp* = *27° 39′, *pp′* = 52° 35′, *co* = 32° 28′, *cq* = 17° 39′, *cr* = 55° 4′, *cp* = 62° 21′.

Crystals usually minute, thin tabular ∥ *c*. Twins very common: (1) tw. pl. *q* ($10\bar{1}6$) f. 2; often in trillings (f. 3), both contact- and penetration-twins. The twinning angle $c\underline{c}$ = 35° 18′, while in trillings it is 70° 36′, approximating closely to the regular octahedron; hence pseudo-isometric forms occur among the compound crystals. (2) *r* ($30\bar{3}4$), often combined with twins (1), $c\underline{c}$ = 69° 52′, also near the octahedral angle. Also united with polysynthetic twinning in fan-shaped groups and spherical rosettes.

Cleavage: prismatic, not distinct; parting ∥ *c*, sometimes observed. Fracture conchoidal.



**Figs. 1–3, Pachuca, Mexico, Rath.**

Brittle. H. = 7. G. = 2·28–2·33. Luster vitreous, on *c* pearly. Colorless to white. Transparent. Optically +. Double refraction weak. Mean refractive index = 1·476 for D, Mld. Often exhibits anomalous refraction phenomena.

A basal section often exhibits a series of differently orientated doubly refracting and biaxial bands, whose existence has been explained[3] by the assumption of a complex twinning of monoclinic or triclinic individuals with a prismatic plane (60°) as twinning-plane. These may be secondary, however, since at a moderately elevated temperature the sections become isotropic and uniaxial[4].

**Comp.**—Pure silica, $SiO_2$, like quartz.

**Pyr.**, **etc.**—Like quartz, but soluble in boiling sodium carbonate.

**Obs.**—Occurs chiefly in acidic volcanic rocks, trachyte, andesyte, liparyte, less often in doleryte; usually in cavities, often associated with sanidine, also hornblende, augite, hematite; sometimes in opal. First observed in crevices and druses in an augite-andesyte from the Cerro San Cristobal, near Pachuca, Mexico; later proved to be rather generally distributed. Thus in trachyte of the Drachenfels and Perlenhardt of the Siebengebirge; of Euganean Hills in N. Italy; Puy Capucin (Mont-Dore) in Central France, and Alleret, Haute Loire; in porphyryte of Waldböckelheim; in augite-andesyte of Gerenczes in Transylvania.

In the ejected masses from Vesuvius consisting chiefly of sanidine. In the andesyte of Krakatau (Zs. Kr., **10**, 174, 1885); at Lyttleton Harbor, near Christchurch, New Zealand, in compound crystals approximating to isometric forms (cf. above, and Rath, Ber. nied. Ges., July 7, 1886). With quartz, feldspar, fayalite in lithophyses of Obsidian cliff, Yellowstone Park. In the andesyte of Mt. Rainier, Washington. In the opal of Zimapan and elsewhere, as in the cacholong of Iceland and Hüttenberg, Carinthia.

Named from τρίδυμος, *three-fold*, in allusion to the common occurrence in trillings.

**Alt.**—The tridymite of the Euganean Hills (pseudo-tridymite, Mld.) has the common form of the species, but, as shown by Mallard, its specific gravity is very near that of quartz, with which it also agrees in optical characters; it is then to be regarded as a paramorph. Bull. Soc. Min., **13**, 162, 1890.

**Artif.**—First formed by Rose by dissolving a silicate in a salt of phosphorus bead, the skeleton of silica, consisting of tridymite; later also by Hautefeuille. Again by Friedel and Sarasin by heating gelatinous silica at a red heat with an alkaline solution in a closed tube. Cf. p. 192; also Fouqué-Lévy, Synth. Min., 85, 1882; Bourgeois, Reprod. Min., 81, 1884. As a recent formation at Plombières (Daubrée). Observed in the vitrified walls of the muffles of a zinc furnace with gahnite and willemite.

**Ref.**—[1] Pogg., **152**, 1, 1874. [2] Mallard on pseudo-tridymite (see above), Bull. Soc. Min., **13**, 162, 1890. [3] Schuster, Min. Mitth., **1**, 71, 1878; Lsx., Zs. Kr., **2**, 253, 1878. [4] Merian, Jb. Min., **1**, 193, 1884.

ASMANITE *Maskelyne*, Phil. Trans., **161**, p. 361, 1871. *Rath*, Pogg., Erg. Bd., **6**, 382, 1873. *Winkler*, Nov. Act. Leopold, Car. Akad., **40**, 339, 1878.

A form of silica found in the meteoric iron of Breitenbach, in very minute grains, generally much rounded and stained with iron on the surface. It is mixed with bronzite (after the removal of the iron, troilite, and chromite), and constitutes about one-third of the mixed siliceous minerals. Also (in irregular particles) in the Rittersgrün iron, making up about one-fourth of the non-metallic portion, with troilite and bronzite, which together form about one-half of the whole.

Described as orthorhombic, with $\breve{a} : \bar{b} : \dot{c} = 1·7437 : 1 : 3·3120$. Observed forms: 100, 001, 110, 013, 012, 023, 011, 043, 116, 112, 223. Angles (calc., Mask.): $110 \wedge 1\bar{1}0 = 59° 40'$, $001 \wedge 011 = 62° 14'$, $001 \wedge 112 = 62° 21'$ (*mm'* = 60°, *cp* = 62° 21' tridymite).

Cleavage: *c* good, with vitreous luster; *m* difficult. Very brittle H. = 5·5. G. = 2·245, Breitenbach. Luster generally resinous, resembling opal. Colorless. Transparent. Optically biaxial, negative. Ax. pl. $\parallel \breve{a}$. $Bx \perp \bar{b}$. $2E = 107°–107\frac{1}{2}°$. Dispersion $\rho > v$. Composition, nearly pure silica. Analyses: 1, 2, Maskelyne, 1 on 0 3114 gr., 2 on 0·2653 gr. 3, Winkler, l. c., p. 358.

| | $SiO_2$ | $Fe_2O_3$ | CaO | MgO | |
|---|---|---|---|---|---|
| 1. Breitenbach | 97·43 | 1·12 | 0·58 | 1·51 | = 100·64 |
| 2. " | 99·21 | 0·79 etc. | | | = 100 |
| 3. Rittersgrün | 97·84 | 1·65 | *tr.* | — | ign. 1 01 = 100·50 |

It has been pretty conclusively proved that asmanite is identical with tridymite, as suggested by Lasaulx (Zs. Kr., **2**, 274, 1878), Weisbach (cf. Winkler, l. c.), and Tschermak, Ber. Ak. Wien, **88** (1), 348, 1883. Groth regards tridymite as orthorhombic and isomorphous with brookite ($TiO_2$).

CRISTOBALITE *G. vom Rath*, Jb. Min., **1**, 198, 1887. Christobalite

In regular octahedrons up to 2 mm., in part spinel twins. Angle *oo'* = 70° 21' Mld. The forms sometimes skeleton-like with depressed faces. No cleavage. H. = 6–7. G. = 2·27 Rath; 2·34 Mld. Luster dull. Color white. Translucent. Shows abnormal double refraction, hence pseudo-isometric Mld. Mean refractive index = 1·432. $\omega - \epsilon = 0·00053$ Mld. Heated to 175° C. the double refraction disappears suddenly, reappearing on cooling.

Composition, pure silica, $SiO_2$. Analysis, Rath, on 0·08 gram, containing some gangue ($Fe_2O_3$, etc.): $SiO_2$ 91·0, $Fe_2O_3,Al_2O_3$ 6·2 = 97·2.

B.B. infusible. Occurs with tridymite in cavities in the andesyte of the Cerro S. Cristobal near Pachuca, Mexico.

The similarity between the pseudo-isometric twinned forms of tridymite and the octahedrons of cristobalite was pointed out by Rath; and the relation between the two forms of silica is minutely discussed by Mallard, Bull. Soc. Min., **13**, 172, 1890.

GRANULINE. Granulina *A. Scacchi*, Rend. Acc. Napoli, **21**, 176, October 1882. A form of silica, probably identical with tridymite, occurring as a white pulverulent incrustation on Vesuvian lava. Very hygroscopic, regaining in the air the water (17·4 p. c.) lost on ignition. G. = 1·73, after ignition 2·20. Readily soluble in sodium carbonate. White pearly hexagonal plates of tridymite occur with it which consist also of silica and water, losing 12·5 p. c. by ignition.

MELANOPHLOGITE *A. v. Lasaulx*, Jb. Min., 250, 627, 1876; 513, 1879. Melanoflogite *G. Spezia*, Mem. Acc. Linc., **15**, 300, 1883.

In minute cubes and spherical aggregates. The cubes have an isotropic crust, while the interior has aggregate polarization like chalcedony. H. = 6·5–7. G. = 2·04. Luster vitreous. Color light brown or colorless. Transparent. The double refraction is sometimes after the analogy of pseudo-isometric species. Mallard (Bull. Soc. Min., **13**, 180, 1890) shows that the crystals are made up of the fibrous melanophlogite turning black upon ignition, with G. = 2·04, with enclosed particles of quartz with G. = 2·65, both probably present by alteration from some earlier mineral.

Analyses.—1, Lasaulx, l. c. 2, Spezia, l. c. 3, Pisani, Bull. Soc. Min., **11**, 298, 1888.

| | | $SiO_2$ | $SO_3$ | $H_2O$ | C | $Fe_2O_3$ |
|---|---|---|---|---|---|---|
| 1. | | 86·29 | 7·20 | 2·86 | — | 0·70 SrO 2·80 = 99·85 |
| 2. | | 89·46 | 5·60 | 2·42 | 1·33 | 0·25 = 99·06 |
| 3. | G. = 2·02 | 91·12 | 5·30 | 1 52 | — | 0 43 ($Al_2O_3$) = 98·37 |

The carbon is present in minute yellow grains whose composition is undetermined; separated by use of hydrofluoric acid and heated on platinum foil they turn black and disappear. The mineral turns black superficially when heated B.B. (hence name from *μέλας*, *black*, and *φλέγεσϑαι*, *to be burned*) in consequence of the presence of this enclosed carbon.

Occurs with calcite and celestite implanted upon an incrustation of opaline silica over the sulphur crystals of Girgenti, Sicily.

This anomalous substance can hardly be regarded as other than of pseudomorphous origin.

SULFURICIN *Guyard*, Bull. Soc. Chim., **22**, 61, 1874. *Brezina*, Min. Mitth., 243, 1876.

A white porous silica, having a sour taste and impregnated with sulphur. From Greece. An analysis gave Guyard: $SiO_2$ 80·38, $SO_3$ 6·80, S 4·10, $H_2O$ 6·10, $Al_2O_3$ 0·43, $Fe_2O_3$ 0 57 (in orig. 8·57), MgO 0·37, CaO 1·25 = 100. Cf. melanophlogite.

VESTAN *Jenzsch*, Pogg., **105**, 320, 1878. A supposed triclinic form of silica from the melaphyre of Saxony and the Thüringer Wald. Cf. 5th Ed., p. 198.

JENZSCHITE *Dana*, Min., 5th Ed., p. 201. A name proposed for certain kinds of opal silica, described by Jenzsch (Pogg., **126**, 497, 1865), having the specific gravity of quartz but soluble in a hot solution of caustic potash. The kinds here referred to are a white cacholong from Hüttenberg in Carinthia, G. = 2·591; from Hutberg, near Weissig, in amygdaloid, G. = 2·633–2·647; from the porphyry of Regensberg, G. = 2·620; from Brazil, G. = 2·596. They are generally associated with chalcedony, and Jenzsch regards them as a result of its alteration.

PASSYITE *E. Marchand*. Ann. Ch. Phys., **1**, 392, 1874. An impure variety of silica occurring in white earthy masses at Contremoulins, Caux, France.

### 212. OPAL. Opalus, Pæderos, *Plin.*, **37**, 21, 22. Quartz resinite *H.*, Tr., **2**, 1801.

Amorphous. Massive; sometimes small reniform, stalactitic, or large tuberose. Also earthy.

H. = 5·5–6·5. G. = 1·9–2·3; when pure 2·1–2·2. Luster vitreous, frequently subvitreous; often inclining to resinous, and sometimes to pearly. Color white, yellow, red, brown, green, gray, blue, generally pale; dark colors arise from foreign admixtures; sometimes a rich play of colors, or different colors by refracted and reflected light. Streak white. Transparent to nearly opaque. Refractive indices, Dx.

$n_r$ = 1·4374, 1·4555 hyalite  1·450 fire-opal  1·442, 1·446 precious opal
$n_r$ = 1·406 white hydrophane  1·446 same, with absorbed water

Often shows double refraction similar to that observed in colloidal substances due to tension. The mammillary form, hyalite, often yields the uniaxial interference cross of a negative substance in parallel polarized light; this is referred to tension by Schultze, Ber. nied. Ges., 69, 1861. The cause of the play of color in the precious opal was investigated by Brewster (Ed. Phil. J., 38, 385, 1845), who ascribed it to the presence of microscopic cavities. Behrends, however, has given a monograph on the subject, Ber. Ak. Wien, **64** (1), 1871, and has shown that this explanation is incorrect; he refers the colors to thin curved lamellæ of opal whose refractive power may differ by 0·1 from that of the mass. These are conceived to have been originally formed in parallel position, but have been changed, bent, and finally cracked and broken in the solidification of the ground-mass.

**Comp.**—Silica, like quartz, with a varying amount of water, $SiO_2.nH_2O$. The water is sometimes regarded as non-essential.

The opal condition is one of lower degrees of hardness and specific gravity, and, as generally believed, of incapability of crystallization. The water present varies from 2 to 13 p. c. or more, but mostly from 3 to 9 p. c. A hyalite gave 3 p. c. $H_2O$; milk-opal 4·3 p. c.; fire-opal 6–8 p. c.; precious opal from Hungary gave 10 p. c.; geyserite 9–13 p. c. Small quantities of ferric oxide, alumina, lime, magnesia, and alkalies are usually present as impurities. Quartz is often mixed with the opal. For analyses, see 5th Ed., p. 198, also Rg., Min. Ch., pp. 164–168, 1875.

**Var.**—1. *Precious Opal.*—Exhibits a play of delicate colors, or, as Pliny says, presents various refulgent tints in succession, reflecting now one hue and now another. Seldom larger than a hazel-nut; a mass in the Vienna museum has the size of a man's fist and weighs 17 oz., but has numerous fissures, and is not wholly free from the matrix. *Harlequin opal* is a kind presenting a variegated play of colors in a reddish ground, resembling the fire-opal.

2. *Fire-opal.* Feueropal, fr. Mexico, *Humboldt*, *Karsten*, Klapr. Beitr., 4, 156, 1807.—Hyacinth-red to honey-yellow colors, with fire-like reflections, somewhat irised on turning.

3. *Girasol.*—Bluish white, translucent, with reddish reflections in a bright light.

4. *Common Opal.*—In part translucent; (*a*) *milk-opal*, milk-white to greenish, yellowish, bluish; (*b*) *Resin-opal* (Wachsopal, Pechopal, *Germ.*), wax-, honey- to ocher-yellow, with a resinous luster; (*c*) dull olive-green and mountain-green; (*d*) brick-red. Includes *Semiopal*, Halbopal *Wern.*; also

(*e*) *Hydrophane*, which is translucent, whitish, or light-colored, adheres to the tongue, and becomes more translucent or transparent in water (to which the name, from *ὕδωρ, water*, and *φαίνεσθαι, to make clear* alludes), a common quality of opal. *Pyrophane* is a name (from *πῦρ, fire*) given to a kind which by the absorption of melted wax is made translucent when hot, but becomes opaque again on cooling. The name has also been used for fire-opal.

(*f*) *Forcherite* Aichhorn [Wien. Ztg. Abendbl., Jul. 11, 1860]; an orange-yellow opal, colored by orpiment; G. = 2·17 Maly (J. pr. Ch., **86**, 501, 1862). It is from Knittenfeld, in Upper Styria.

*Blackmorite* A. C. Peale (Hayden's, 6 Ann. Rep., U. S. G. S., 169, 1873) is a yellow variety of opal from Mt. Blackmore, Montana. Analysis gave: $SiO_2$ 85·20, $H_2O$ at 110° 7·40, ign. 2·40, $Fe_2O_3$ 2·68, CaO 1·48 MgO 0·37, $Na_2O$ *tr.* = 99·53; G. = 2·172.

5. *Cacholong.* Kascholong *Germ.* Perl-mutter-opal *Karst.*, Tab., 1808.—Opaque, bluish white, porcelain-white, pale yellowish or reddish; often adheres to the tongue, and contains a little alumina. The word is of Tatar origin.

6. *Opal-agate.*—Agate-like in structure, but consisting of *opal* of different shades of color.

7. *Menilite.* Pechstein de Menil Montant *Delarbre & Quinquet*, J. de Phys., **31**, 219, 1787; Menilite *de Saussure*, Delameth. T. T., **2**, 169, 1797. Leberopal *Karst.*, Tab., 24, 1800.—In concretionary forms, tuberose, reniform, etc., opaque, dull grayish, grayish brown, occurring embedded in a shaly argillaceous deposit.

8. *Jasp-opal.* Karst. Tab., 26, 1808; Opal-jasper, Eisenopal, *Hausm.*, Handb., 428, 1813.—Opal containing some yellow iron oxide and other impurities, and having the color of yellow jasper, with the luster of common opal.

9. *Wood-opal.* Holz-opal *Germ.*—Wood petrified by opal; sometimes called lithoxyle when showing a woody structure.

10. *Hyalite.* Mullerisches Glas [= Muller's Glass, after the discoverer]; Hyalit *Wern.*, Hoffm. Min., **2**, *a*, 134, 1812, *Karst.*, Tab., 22, 1800; Gummistein *Blumenb.*, Nat., 553; Glasopal *Hausm.*, Handb., 424, 1813. Jalite *Ital.*—Clear as glass and colorless, constituting globular concretions, and also crusts with a globular, reniform, botryoidal, or stalactitic surface; also passing into translucent, and whitish. Less readily dissolved in caustic alkalies than other varieties.

11. *Fiorite, Siliceous Sinter.* Kieselsinter *Germ.*; *Santi*, Viaggio al Montomiata, Pisa, 1795, Crell's Ann., **2**, 589, 1796; *Thomson*, J. de Phys., **39**, 407, 1791. Breve Notizia di un Viaggiatore sulle Incrost. Sil. termali d'Italia, etc., 1795, Crell's Ann., **1**, 108, 1796, Bibl. Brittan, 185, 1796 (? name fiorite here given); *Pfaff.*, Crell's Ann., **2**, 589, 1796; Resinite termogino (*Ital.*).

Includes translucent to opaque, grayish, whitish, or brownish incrustations, porous to firm in texture; sometimes fibrous-like or filamentous, and, when so, pearly in luster (then called *Pearl-sinter*); formed from the decomposition of the siliceous minerals of volcanic rocks about fumaroles, and deposited from the siliceous waters of hot springs, in part by the action of vegetation. It graduates at times into hyalite.

(*a*) The original *fiorite* (or pearl-sinter), as described by Thomson, occurs in tufa in the vicinity of Santa Fiora, Italy, and also on Ischia, and at the Solfatara near Naples, in globular, botryoidal, and stalactitic concretions, pearly in luster. Thomson also mentions (1791) a similar incrustation as formed from the hot waters of the Sasso lagoons. It was referred by Werner to hyalite in 1816.

(*b*) The *Michaelite* (J. W. Webster, Am. J. Sc., **3**, 391, 1821) is similar, from the island of St. Michaels, one of the Azores, where it occurs in snow-white incrustations, capillary or filiform in structure, pearly in luster, with G. = 1·866.

(*c*) *Geyserite.* Kieseltuff (fr. Geysers) *Klapr.*, Beitr., **2**, 109, 1797; Geysirite *Delameth.*, Min., 1812; Damour, Bull. G. Fr., 157, 1848. Constitutes concretionary deposits about the geysers of the Yellowstone Park, Iceland, and New Zealand, presenting white or grayish, porous, stalactitic, filamentous, cauliflower-like forms, often of great beauty; also compact-massive, and scaly-massive; H. = 5; rarely transparent, usually opaque; sometimes falling to powder on drying in the air. *Pealite* F. M. Endlich (Hayden's 6 Ann. Rep., U. S. G. S., p. 153, 1873) is a variety of geyserite from the Yellowstone region containing but a small amount of water; one sample gave 1·5 p. c. with G. = 2·49. Named after A. C. Peale, chemist to the U. S. G. S. *Viandite* E. Goldsmith (ibid., 12 Ann. Rep., Pt. II, 407, 1883) is a form of silica, deposited by some of the hot springs of the Yellowstone Park, in thin sheets or sponge-like forms resembling a vegetable growth. It becomes soft and leather-like when dry. Contains when first collected a large, but probably not definite, quantity of water; this is estimated as forming 80 p. c. of the whole.

Analyses of ordinary geyserite from the Yellowstone region by A. C. Peale gave 9–13·4 p. c. $H_2O$; others from the Steamboat Springs, Nevada, by R. W. Woodward, gave 5·5 p. c. (U. S. G. S., 40th Par., **2**, 826, 1877). For description of thermal springs, etc., see A. C. Peale, Hayden's 12 Ann. Rep., U. S. G. S., Pt. II, pp. 65, 448, analyses (and by Leffmann) on p. 411, also (Iceland, New Zealand, quoted) p. 413. Leffmann's analyses are also given in Ch. News, **43**, 124, 1881. On the essential part played by vegetable growth in the deposition of siliceous sinter, see Weed, Am. J. Sc., **37**. 351, 1889, with analyses by Whitfield; also U. S. G. Surv., 9 Ann. Rep., pp. 619–676.

12. *Float-stone.* Quartz nectique, *H.*, Tr., **2**, 1801; Schwimmstein *Germ.*—In light concretionary or tuberose masses, white or grayish, sometimes cavernous, rough in fracture. So light, owing to its spongy texture, as to float on water. The concretions sometimes have a flint-like nucleus.

13. *Tripolite.* Tripel, Terra Tripolitana (fr. Tripoli, in part), *Wall.*, 32, 1747. Infusorial earth; Bergmehl, Kieselmehl, Kieselguhr, *Germ.* Farina fossilis. Randanite *Salvetat*, Ann. Ch. Phys., **24**, 348, 1848.—Formed from the siliceous shells of Diatoms (hence called *diatomite*) and other microscopic species, as first made known by Ehrenberg, and occurring in deposits, often many miles in area, either uncompacted or moderately hard. (*a*) *Infusorial Earth*, or *Earthy Tripolite*, a very fine-grained earth looking often like an earthy chalk, or a clay, but harsh to the feel, and scratching glass when rubbed on it.

(*b*) *Randannite* (*Randanite* wr. orthog.), a kaolin-like variety from Ceyssat (Ceyssatite *Gonnard*, Lyon, Feb. 15, 1875, who explains that the hamlet Randanne has been confounded with the larger town Randan) and Randanne, in Dept. Puy-de-Dôme, and from Algiers, with 9 to 10 p. c. $H_2O$. A deposit at Santa Fiora in Tuscany was made known by G. Fabbroni in 1794 (Giorn. Fis.-med di D. Brungnatelli, p. 154; Crell's Ann., **2**, 199, 1794; Bergmehl v. Santa Fiora *Klaproth*, Beitr., **6**, 348). It consists of a grayish white, loose, mealy earth; Fabbroni states that he made bricks of it which would float like those which Pliny described as made in Spain from a sort of pumice-like earth (**35**, 49), and supposes the material the same. Ehrenberg has shown it to be an infusorial earth.

(*c*) *Tripoli slate* (Polishing slate, Polirschiefer, Tripelschiefer, Saugkiesel, Klebschiefer, *Germ.*), a slaty or thin laminated variety, fragile; G. = 1·909–2·08. Often much impure from mixture with clay, magnesia, iron oxide, etc. (*d*) *Alumocalcite* (fr. Eibenstock, *Breith.*, Char., 97, 326, 1832) is a milk-white material, having a hardness of only 1 to 1½; G. = 2·174; it may be a variety of tripolite, containing a little lime and alumina.

**Pyr., etc.**—Yields water. B.B. infusible, but becomes opaque. Some yellow varieties, containing iron oxide, turn red. Soluble in hydrofluoric acid somewhat more readily than quartz; also soluble in caustic alkalies, but more readily in some varieties than in others.

**Obs.**—Occurs filling cavities and fissures or seams in igneous rocks, as trachyte (Opalmutter *Germ.*) porphyry, also in some metallic veins. Also embedded, like flint, in limestone, and sometimes, like other quartz concretions, in argillaceous beds; also formed from the siliceous waters of some hot springs; also resulting from the mere accumulation, or accumulation and partial solution and solidification, of the siliceous shells of infusoria, of sponge spicules, etc.,—which consist essentiallyof opal-silica. The last mentioned is the probable source of the opal of limestones and argillaceous beds (as it is of flint in the same rocks), and of part of that in igneous rocks. It exists in most chalcedony and flint. Common opal and hyalite are products of the decomposition of a Roman cement at the hot springs of Plombières in France.

*Precious opal* occurs in porphyry at Czerwenitza, near Kashau in Hungary; at Frankfort; at Gracias a Dios in Honduras; Esperanza, Queretaro in Mexico, with fire-opal, milk-opal, and other kinds; a beautiful blue opal, with delicate play of colors, on Bulla Creek, Queensland (Phil. Soc. Glasgow, **13**, 427, 1882); Abercrombie R., New South Wales. *Fire-opal* occurs at Zimapan in Mexico; the Färöer; near San Antonio, Honduras. *Common opal* is abundant at Telkebánya in Hungary; near Pernstein, Luckau, and Smrezet in Moravia; in Bohemia; at Kosemütz in Silesia; Hubertsburg in Saxony; Stenzelberg and Quegstein in Siebengebirge; Steinheim near Hanau; in Iceland; the Giant's Causeway, and the Hebrides; also within ½ m. and to the S.W. of the watering-place at Vourla, the harbor of Smyrna, with yellow jasper and hornstone, embedded in a low ridge of yellowish compact limestone; of a wax-yellow and grayish green color, occasionally white, at the Giant's Causeway. *Hyalite* occurs in amygdaloid at Schemnitz, Hungary; in clinkstone at Waltsch, Bohemia. *Wood-opal* forms large trees in the pumice conglomerates of Saiba, near Neusohl; Kremnitz, Hungary; near Hobart Town, Tasmania; and in many other regions of igneous rocks.

In U. S., *hyalite* occurs sparingly in N. York, at the Phillips ore bed, Putnam Co., in thin coatings on granite; in connection with the trap rock of New Jersey and Connecticut; rarely in N. C., Cabarrus Co., with the auriferous quartz; in Georgia, in Burke and Scriven Cos., lining cavities in a siliceous shell-rock; in Washington Co., good fire-opal; at the Suanna spring, Florida, small quantities of siliceous sinter. A remarkable specimen of hydrophane from Colorado absorbed half its own volume of water and became perfectly transparent (Kunz, Am. J. Sc., **34**, 479, 1887, Church, Min. Mag., **8**, 181, 1889). A water-worn specimen of fire-opal has been found on the John Davis river, in Crook Co., Oregon.

Common opal is found at Cornwall, Lebanon Co., Penn.; at Aquas Calientes, Idaho Springs, Col.; a white variety at Mokelumne Hill, Calaveras Co., Cal., and on the Mt. Diablo range. Geyserite occurs in great abundance and variety in the Yellowstone region (cf. above); also siliceous sinter at Steamboat Springs, Nevada. Other localities are given by Kunz, Gems and Precious Stones of N. A., 1890.

**Artif.**—Formed by the gradual drying of a siliceous jelly. See Fouqué-Lévy, Synth. Min., 92, 1882; Btd., Bull. Soc. Min., **3**, 57, 1880.

LUSSATITE *Mallard*, Bull. Soc. Min., **13**, 63, 1890. A form of silica, similar in structure to chalcedony but having a low specific gravity, G. = 2·04, near that of opal; refractive index (for D) 1·446 like opal, but crystalline and optically *positive*. It consists of pure silica, probably anhydrous, and is associated with true amorphous opal-silica. Observed in the well-known blue "chalcedony" of Tresztyan, Hungary; also forming an envelope with fibrous structure over clear quartz crystals in the bitumen of Lussat, near Pont-du-Chateau, Puy-de-Dôme; also from Cornwall; the Färöer. Cf. also observations on chalcedony, p. 188.

Colloid silica, probably directly derived from the remains of siliceous sponges, occurs in beds in the Lower Chalk of Berkshire and Wilton, England, similar to the malmstones of the Greensand. Jukes-Browne, Q. J. G. Soc., **45**, 403, 1889; Hinde, Phil. Trans., pt. 2, 403, 1885.

TABASHEER. Tabaschir *Germ.* Amorphous, opal-like silica deposited within the joints of the bamboo. Color milk-white. G. = 0·54 and when calcined less than 0·67. Refractive index, $n_r = 1{\cdot}119$ Dx. It absorbs water and becomes translucent like hydrophane; in certain oils it becomes as transparent as glass with a remarkable increase in refractive power. See Hintze, Zs. Kr., **13**, 392, 1887; Blasius, ib., **14**, 258, 1888; also Judd, Nature, **35**, 488, 1887.

### 1. Arsenolite Group. $R_2O_3$. Isometric.

**213. ARSENOLITE.** Arsenicum nativum farinaceum, A. n. crystallinum, *Wall.*, 224, 1747. A. calciforme *Cronst.*, 207, 1758. A. cubicum, etc., *Linn.*, 1768. White arsenic *Hill*, 1771. Natürlicher Arsenikkalk. Arsenikblüthe *Karst.*, Tab., 79, 1800. Arsenic oxidé *H.* Arsenit *Haid.*, Handb., 487, 1845. Arsenolite *Dana*, Min., 139, 1854. White arsenic, Arsenious acid, Arsenious oxide. Arsenige Säure *Germ.* Arsenikblomma *Swed.* Acide arsenieux, Arsenic blanc natif *Fr.* Arsenico bianco *Ital.* Arsenico blanco, Acido arsenioso *Span.*

Isometric. In octahedrons. Usually in minute capillary crystals, in stellar aggregates, or as crusts. Also botryoidal, stalactitic; earthy.

H. = 1·5. G. = 3·70–3·72. Luster vitreous or silky. Color white, occasionally with a yellowish or reddish tinge. Streak white, pale yellowish. Transparent to opaque. Taste astringent, sweetish. Refractive indices: $n_r$ = 1·748 Li, $n_y$ = 1·755 Na at 17° C., Dx.[1] Sometimes shows anomalous double refraction[1].

**Comp.**—Arsenic trioxide, $As_2O_3$ = Oxygen 24·2, arsenic 75·8 = 100.

**Pyr., etc.**—Sublimes in the closed tube, condensing above in minute octahedrons. B.B. on charcoal volatilizes in white fumes, giving a white coating and an alliaceous odor. Slightly soluble in hot water.

**Obs.**—Accompanies ores of silver, lead, arsenical iron, cobalt, nickel, antimony, etc., as a result of the decomposition of arsenical ores. Occurs at Andreasberg in the Harz; at Wheal Sparnon in Cornwall; Joachimsthal in Bohemia; Kapnik in Hungary; the old mines of Bieber in Hanau; the Ophir mine, Nevada; the Armagosa mine, Great Basin, California.

**Alt.**—Native arsenic is often covered by a blackish crust or powder, which has been considered a suboxide; but according to Suckow, it is a mixture of metallic arsenic and arsenic trioxide.

**Ref.**—[1] See references under senarmontite.

**214. SENARMONTITE.** Antimoine oxydé octaédrique *H. de Senarmont*, Ann. Ch. Phys., **31**, 504, 1851. Senarmontite *Dana*, Am. J. Sc., **12**, 209, 1851.

Isometric; in octahedrons. Also granular massive; in crusts.

Cleavage: octahedral, in traces. H. = 2–2·5. G. = 5·22–5·30. Luster resinous, inclining to subadamantine. Transparent to translucent. Colorless or grayish. Streak white. Refractive indices: $n_r$ = 2·073, $n_y$ = 2·087 Dx.[1] Anomalous double refraction strongly marked, resembling boracite[1].

**Comp.**—Antimony trioxide, $Sb_2O_3$ = Oxygen 16·7, antimony 83·3 = 100.

**Pyr., etc.**—In the closed tube fuses and partially sublimes. B.B. on charcoal fuses easily, and gives a white coating; this treated in R.F. colors the outer flame greenish blue. Soluble in hydrochloric acid.

**Obs.**—A result of the decomposition of stibnite and other ores of antimony. First found in the district of Haraclas in Algeria; occurs also at Perneck near Malaczka in Hungary. Endellion in Cornwall; the antimony mine of S. Ham, Wolfe Co., Quebec, Canada. The octahedrons from Algeria are sometimes nearly ½ inch in diameter.

Named after H. de Senarmont (1808–1862), who first described the species.

**Ref.**—[1] Cf. Dx., N. R., 3, 9, 1867; Mld., Ann. Mines, **10**, 108, 1876; Groth, Pogg., **137**, 1869; Grosse-Bohle, Zs. Kr., **5**, 222, 1880; Prendel, Min. Mitth., **11**, 7, 1889.

**Alt.**—Crystals from South Ham have been noted which were superficially altered to stibnite; 428, also others changed throughout, by paramorphism, to valentinite (Hintze).

---

## 2. Valentinite Group. $R_2O_3$.

**215. CLAUDETITE.** Prismatic Arsenious Acid *F. Claudet*, Proc. Ch. Soc., 1868, Ch. News, **22**, 128, 1868; Claudetite *Dana*, Min., 796, 1868. Rhombarsenite *Adam*, Tabl. Min., 41, 1869. Arsenphyllite. Acide arsénieux prismatique *Fr.*

Monoclinic. Axes $\grave{a} : \bar{b} : \grave{c}$ = 0·4040 : 1 : 0·3445; β = 86° 3′ = 001 ∧ 100 Schmidt [1].

100 ∧ 110 = 21° 57′, 001 ∧ 101 = 38° 47′, 001 ∧ 011 = 18° 58′.

**Forms**[1]:

bo = *75° 48′
oγ = *37° 24′
a′g = 53° 23½′
gg′ = 30° 19′

Crystals in thin plates, resembling selenite; tabular ‖ *b*, with the pyramids *o*, *g* prominent; often penetration-twins, with *a* as twinning-plane.

Cleavage: *b* perfect; fibrous fracture ‖ *m*. Flexible like selenite. H. = 2·5. G. = 3·85 Claudet; 4·151 Groth. Luster on cleavage surface pearly, otherwise vitreous. Colorless to white. Transparent to translucent. Optically +. Ax. pl. ‖ *b*. Bx ∧ $\grave{c}$ = + 5½°. $2H_r$ = 66° 14′ Li, $2H_y$ = 65° 21′ Na. Dispersion $\rho < v$.

**Comp.**—Arsenic trioxide, like arsenolite, $As_2O_3$ = Oxygen 24·2, arsenic 75·8 = 100.

**Pyr.**—As for arsenolite.

**Obs.**—Occurs in seams in an ore of arsenical pyrites, at the San Domingo mines, Portugal. Also observed as the result of the burning of a mine at Szomolnok (or Schmöllnitz) in Hungary, Szabo, Földt. Közl., **18**, 49, 1888, Schmidt, l. c.

**Alt.**—Crystals consisting of octahedral crystals (paramorphs) have been noted, Ulrich.

**Ref.**—[1] Szomolnok, Zs. Kr., **14**, 575, 1888. Cf. also Dx., Bull. Soc. Min., **10**, 303, 1887. Groth (Pogg., **137**, 414, 1869), who made the crystals orthorhombic, observed on crystals from a Freiberg furnace, a number of other planes, which are thus referred by Schmidt to the monoclinic axes, viz.: (1·0·12) = 001, γ (1·12·12) = 011, (210), μ (250), ν (150), *n* (171). α (1·48·12) = 041, β (1·24·12) = 021. [2] Schmidt, l. c.

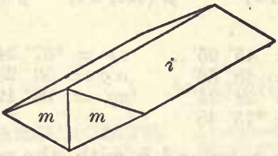
uu‴ = 80° 44′
vv′ = 52° 44′
vv‴ = 40° 39′
xx′ = 48° 15′

Commonly prismatic either ∥ ċ (*m*) or ă (*i*, *g*, *q*, *r*, or *s*); also tabular ∥ *b*; often rounded by striations ∥ *m*/*m*′ and ∥ *i*/*i*′. Crystals often aggregated in fan-shaped or stellar groups, in bundles and druses and as aggregations of thin plates. Also massive; structure lamellar, columnar, granular.

Cleavage: *b* perfect; also *m*. H. = 2·5–3. G. = 5·566. Luster adamantine, *b* often pearly; shining. Color snow-white, occasionally peach-blossom red, and ash-gray to brownish. Streak white. Translucent to subtransparent.

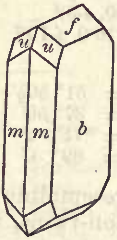
Ax. pl. ∥ *c* for red rays, ⊥ *c* for blue, for yellow nearly uniaxial; dispersion $\rho > v$ strong (Bräunsdorf); also in other crystals (Přibram, Algeria), the axes for red are sensibly united, those for other colors lie ⊥ *c*, and $\rho > v$. Bx always ⊥ *a*; axial angles small. Heated to 75° C. the axes ∥ *c* unite slightly, those ⊥ *c* open slightly, Dx[3].

1.



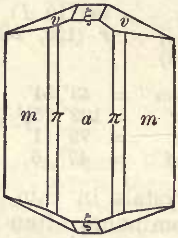
Bräunsdorf, Lasp.

2.



Přibram, Id.

3.



Constantine, Id.

**Comp.**—Antimony trioxide, $Sb_2O_3$ = Oxygen 16·7, antimony 83·3 = 100.

**Pyr., etc.**—Same as for senarmontite.

**Obs.**—Occurs with other antimonial ores, and results from their alteration. Found at Přibram in Bohemia, in veins traversing metamorphic rocks; at Felsöbánya in Hungary, with stibnite and arsenopyrite; Malaczka in Hungary; Bräunsdorf near Freiberg in Saxony; Allemont in Dauphiné; Sempsa, Province of Constantine, Algiers. Also at the antimony mine of South Ham, Wolfe Co., Quebec; with native antimony at the Prince William mine, York Co., N. B.

The *prismatic* form of $Sb_2O_3$ is obtained from solutions at a temperature above 100° C.

Named after Basil Valentine, an alchemist of the 15th century, who discovered the properties of antimony.

**Alt.**—Observed as a paramorph after senarmontite.

**Ref.**—[1] Mean of results for Bräunsdorf crystals, Zs. Kr., **9**, 162, 1884; cf. also Groth, Pogg., **137**, 429, 1869; Tab. Ueb., 84, 1874; and Brezina, Ann. Mus. Wien, **1**, 145, 1886; the last suggests *i* as 011, but without very distinct advantage. [2] See Brz. for critical summary of results of earlier authors, also Lasp., who adds many new planes. [3] N. R., 58, 1867, also Groth, l. c.

*Antimonophyllite* of Breithaupt, of unknown locality, occurring in thin angular six-sided prisms, is probably valentinite.

---

**217. BISMITE.** Bismuth trioxide, Bismuth Ocher *pt.* Wismuthoxyd, Wismuthocker, *Germ.* Bismuth oxydé *Fr.* Bismutocra *Ital.* Bismite *Dana*.

Orthorhombic. Axes $\breve{a} : \bar{b} : \dot{c}$ = 0·8166 : 1 : 1·0649 Nordenskiöld[1].

**Forms** (artif.): *c* (001, *O*); *m* (110, *I*); *q* (034, $\frac{3}{4}$-ĭ), *r* (011, 1-ĭ), *s* (032, $\frac{3}{2}$-ĭ), *t* (031, 3-ĭ).
Angles: *mm*‴ = *78° 28′, *rr*′ = 93° 36′, edge *m*/*m*′ ∧ *r*/*m* = *129° 31′.

Habit of artif. cryst. prismatic. Natural mineral not crystallized; occurs massive and disseminated, pulverulent, earthy; also passing into foliated.

Fracture conchoidal to earthy. G. = 4·361 Büsson. Luster adamantine to dull, earthy. Color greenish yellow, straw-yellow, grayish white.

**Comp.**—Bismuth trioxide, $Bi_2O_3$ = Oxygen 10·4, bismuth 89·6 = 100. Iron and other impurities often present.

**Pyr., etc.**—In the closed tube most specimens give off water. B.B. on charcoal fuses, and is easily reduced to metallic bismuth, which in O.F. gives a yellow coating of oxide. Soluble in nitric acid.

**Obs.**—Occurs pulverulent at Schneeberg in Saxony, at Joachimsthal in Bohemia; with native gold at Berezov in Siberia; in Cornwall, at St. Roach, and near Lostwithiel.

Dr. Jackson reports an oxide of bismuth not carbonated, as occurring with the tetradymite of Virginia.

See further, BISMUTITE, p. 307, which includes some bismuth ocher.

**Ref.**—[1] Öfv. Ak. Stockh., **17**, 447, 1860, and Pogg., **114**, 622, 1861.

KARELINITE *Hermann*, J. pr. Ch., **75**, 448, 1858. Massive. Structure crystalline. Cleavage in one direction rather distinct. H. = 2. G. = 6·60. Luster strongly metallic within. Color lead-gray. Analysis, Hermann: O [5·21], S 3·53, Bi 91·26 = 100.

From the Savodinski mine in the Altai, with hessite. The mineral is not homogeneous, containing along with the metallic substance a gray, earthy mass of bismutite. By treating the powdered mass with hydrochloric acid, a metallic powder remains, free from any native bismuth, which is the supposed mineral karelinite. Named after Mr. Karelin, the discoverer.

VANADIC OCHER. Vanadic acid *Teschemacher*, Am. J. Sc., **11**, 233, 1851. A yellow pulverulent substance, encrusting masses of native copper, along with quartz, at the Cliff mine, Lake Superior, according to Teschemacher. The color before the blowpipe changed to black; also the powder, boiled in nitric acid, afforded an apple-green solution, from which, on partial evaporation, after standing some weeks, red crystalline globules formed on the surface, which, as they enlarged, fell to the bottom; by means of these crystalline masses the vanadates of silver and lead were made. As no metal was found in the first solution, the yellow mineral was inferred to be probably vanadic oxide.

TANTALIC OCHER. Tantalochra *A. E. Nordenskiöld*, Finl. Min., 27, 1855. A tantalic ocher of brownish color occurring on crystals of tantalite at Pennikoja in Somero, Finland.

---

## 3. Tellurite Group. $RO_2$. Orthorhombic.

**218. TELLURITE.** Tellurige Säure *Petz*, Pogg., **57**, 478, 1842. Tellurite *Nicol*, Min., 429, 1849. Tellurocker *Rg.*, Min. Ch., 175, 1875.

Orthorhombic. Axes $\breve{a} : \bar{b} : \dot{c} = 0·45656 : 1 : 0·46927$ Brezina[1].

$100 \wedge 110 = 24° \, 32\frac{1}{3}'$, $001 \wedge 101 = 45° \, 47\frac{1}{6}'$, $001 \wedge 011 = 25° \, 8\frac{1}{3}'$.

**Forms**[2]: *b* (010, *i*-ĭ), *m* (110, *I*), *r* (120, *i*-2̆), *s* (140, *i*-4̆), *p* (111, 1).

Angles: *mm‴* = 49° 5′, *rr′* = 95° 12′, *ss′* = 57° 18′, *pp′* = 85° 53′, *pp″* = *96° 58·8′, *pp‴* = 36° 14′, *bp* = *71° 52·8′.

In slender prismatic crystals, tabular ‖ *b*, and often striated vertically; also grouped in tufts; in spherical masses with radiated structure.

Cleavage: *b* perfect. Flexible. H. = 2. G. = 5·90. Luster subadamantine. Color white, yellowish white, honey- or straw-yellow. Transparent to translucent. Optically —. Ax. pl. ‖ *a*. Bx ⊥ *b*. $2H_y = 140° \, 8'$ Na ($n = 1·6567$) Knr.

**Comp.**—Tellurium dioxide, $TeO_2$ = Oxygen 20·4, tellurium 79·6 = 100.

**Pyr.**—In the open tube fuses, when strongly heated, to brown drops and sublimes.

**Obs.**—With native tellurium at Fačzebaja and Zalathna, Transylvania. In cavities in and as an incrustation on native tellurium at the Keystone, Smuggler, and John Jay mines, Boulder Co., Colorado.

**Ref.**—[1] Fačzebaja, Ann. Mus. Wien, **1**, 135, 1886; cf. Knr. [Term. Füz., **10**, 81, 106, 1886], Zs. Kr., **13**, 69. [2] Brz., l. c.; vicinal planes *o* (3·16·0), *n* (3·34 0), *π* (1·42·1) also appear.

SELENOLITE. Selenious oxide ($SeO_2$) is noted by Bertrand as probably occurring with some selenium minerals at Cacheuta, Argentine Republic. Bull. Soc. Min., **5**, 92, 1882.

---

## 4. Molybdite Group.

**219. MOLYBDITE.** Molybdena or Molybdic Ocher. Molybdic Acid. Molybdänocker, Molybdänoxyd, Molybdänsäure *Germ.* Molybdine *Greg & Lettsom*, Dana, Min., 144, 1854. Brit. Min., 348, 1858. Molybdite *Breith.*, B. H. Ztg., **17**, 125, 1858.

Orthorhombic. Axes $\breve{a} : \bar{b} : \dot{c} = 0·3874 : 1 : 0·4747$ Nordenskiöld[1].

**Forms**: *a* (100, *i*-ī), *b* (010, *i*-ĭ), *c* (001, *O*); *m* (110, *I*), *μ* (430, *i*-$\frac{4}{3}$), *t* (103, $\frac{1}{3}$-ī), *s* (102, $\frac{1}{2}$-ī), *r* (203, $\frac{2}{3}$-ī).

Angles, *mm‴* = 42° 16′, *bμ* = *73° 48′, *cs* = *31° 30′.

In capillary crystallizations, tufted and radiated; also subfibrous massive; and as an earthy powder or incrustation.

Cleavage: *c* distinct; also *a* and *b*. H. = 1–2. G. = 4·49–4·50 Weisbach. Luster of crystals silky to adamantine, on *c* pearly; earthy. Color straw-yellow, yellowish white. Optically +. Ax. pl. ∥ *a*. Bx ⊥ *c*. Axial angles, Dx.[2]:

$$2H_{o.r} = 117° \ 15' \qquad 2H_{o.y} = 119° \ 23' \qquad 2H_{o.bl} = 127° \text{ approx.}$$

**Comp.**—Molybdenum trioxide, $MoO_3$ = Oxygen 33·3, molybdenum 66·7 = 100.

**Pyr., etc.**—B.B. on charcoal fuses and coats the charcoal with minute yellowish crystals of molybdic oxide near the assay, becoming white near the outer edge of the coating. This coating treated for an instant in R.F. assumes a deep blue color, which changes to dark red on continued heating. With borax gives in O.F. a yellow bead while hot, becoming colorless on cooling; in R.F. a saturated bead becomes brown or black and opaque. With salt of phosphorus gives a yellowish bead in O.F., becoming green when treated in R.F. and allowed to cool.

**Obs.**—Occurs with molybdenite, from which it is probably derived, at the foreign localities of that species; Adun-Chalon Mts. in Eastern Siberia, and at Pitkäranta on L. Ladoga, in silky tufts of capillary crystals.

In N. Hamp., at Westmoreland, earthy; in Penn., at Chester, Delaware Co.; Georgia, Heard Co., in silky fibrous tufts; in the gold region, a few miles north of Nevada City, Cal., in subfibrous masses, and tufted crystallizations of a deep yellow color (*molybdate of iron* of D. D. Owen, Proc. Ac. Philad., 6, 108 but shown by Genth to be this species mixed with limonite).

**Ref.**—[1] Artif. cryst., Öfv. Ak. Stockh., **17**, 300. 1860, Pogg., **112**, 160. [2] N. R., 26, 1867.

ILSEMANNITE *H. Höfer*, Jb. Min., 566, 1871. Crypto-crystalline. Color blue-black to black, on exposure becoming blue. Soluble in water, giving a deep blue solution. The solution contained on analysis chiefly a molybdate of molybdic oxide, and yielded on evaporation deep blue crystals, which were considered to be identical with the known compound $MoO_2.4MoO_3$, which is also supposed to be the composition of the mineral. A product of the decomposition of metallic molybdates, and occurs embedded in barite and associated with wulfenite at Bleiberg in Carinthia. Named after Mining Commissioner J. C. Ilsemann (1727–1822).

**220. TUNGSTITE.** Tungstic Ocher *B. Silliman*, Am. J. Sc., 4, 52, 1822. Wolframocker, Wolframsäure, Scheelsäure *Germ.* Wolframine *Lettsom & Greg*, Dana, Min., 1854, Brit. Min., 349, 1858.

Orthorhombic. Axes: $\breve{a} : \bar{b} : \acute{c}$ = 0·7002 : 1 : 0·3991 Nordenskiöld[1].

**Forms:** *a* (100, *i-ī*), *c* (001, *O*); *m* (110, *I*), *n* (021, *2-ī*). Rather uncertain 031, 041, 051, 081. Angles: *am* = *35°, *cn* = *38° 36′.

Pulverulent and earthy. Color bright yellow, or yellowish green.

**Comp.**—Tungsten trioxide, $WO_3$ = Oxygen 20·7, tungsten 79·3 = 100.

**Pyr., etc.**—B.B. on charcoal becomes black in the inner flame, but infusible. With salt of phosphorus gives in O.F. a colorless or yellowish bead, which treated in R. F. gives a blue glass on cooling. Soluble in alkalies, but not in acids.

**Obs.**—Occurs with wolframite in Cumberland, and Cornwall, England; at Lane's mine, Monroe, Ct., filling small cavities in other ores of tungsten, or coating them, and has resulted from their decomposition; in Cabarrus Co., N. C.; at St. Leonard, near Limoges, rarely in distinct crystals of a sulphur-yellow color on wolframite and quartz.

**Ref.**—[1] Artif. cryst., Öfv. Ak. Stockh., **17**, 449, 1860, and Pogg., **114**, 623, 1861.

---

MEYMACITE *Carnot*, C. R., 79, 639, 1874.

A hydrated tungstic oxide, formed from the alteration of scheelite. Sometimes yellow or greenish yellow, with the structure and cleavage of scheelite; sometimes when the alteration has been more complete, the mineral is friable between the fingers and has a yellow or brownish color. Luster resinous.

Analyses: 1 and 2 on friable material, color yellow to brownish, streak sulphur-yellow. G. = 3·80. 3, firm, with lamellar structure and yellowish streak. G. = 4·54.

| $WO_3$ | $Ta_2O_5$ | $Fe_2O_3$ | $Mn_2O_3$ | CaO | $H_2O$ | gangue | |
|---|---|---|---|---|---|---|---|
| 71·85 | 1·00 | 6·00 | 0·75 | 2·50 | 12·93 | 4·50 | = 99·53 |
| 74·25 | 1·05 | 6·10 | 0·65 | 4·65 | 11·75 | 1·85 | = 100·30 |
| 75·12 | 0·70 | 6·25 | 0·32 | 7·00 | 6·85 | 2·55 | = 98·79 |

Deducting the calcium tungstate and hydrated iron oxide, regarded as impurities, Carnot deduces the formula $WO_3.2H_2O$. In the tube gives off water. On charcoal turns black. With salt of phosphorus, gives in the O.F. a yellow bead, nearly colorless on cooling. In R.F. gives a bead colored violet to red (iron and tungsten together). With acids gives the reaction of tungsten when treated in the usual way.

Found with wolframite and scheelite at Meymac, Corrèze, France.

**221. CERVANTITE.** Spiesglanzokker pt. *Karst.*, Mus. Lesk., **1**, 534, 1789, Tab., 54, 78, 1800. Antimony Ocher pt. Antimonocker pt. *Germ.* Gelbantimonerz (from Hungary) *Breith.*, Char., 98, 1823. 224, 1832. Acide antimonieux *Dufr.*, Min., **2**, 654, 1845. Antimonous Acid, Antimonoso-antimonic Oxide. Cervantite *Dana*, Min., 1854.

Orthorhombic. In acicular crystallizations. Also massive; as a crust, or a powder.

H. = 4–5. G. = 4·084. Luster greasy or pearly, also bright or earthy. Color isabella-yellow, sulphur-yellow, or nearly white, sometimes reddish white. Streak yellowish white to white.

**Comp.**—$Sb_2O_4$ or $Sb_2O_3.Sb_2O_5$ = Oxygen 21·1, antimony 78·9 = 100.

**Pyr., etc.**—B.B. infusible and unaltered; on charcoal easily reduced. Soluble in hydrochloric acid.

**Obs.**—Occurs at various mines of stibnite, and results from the alteration of this and other antimonial ores. Found at Cervantes in Galicia, Spain; Chazelles in Auvergne; Felsöbánya, Kremnitz, and elsewhere in Hungary; Pereta in Tuscany; near St. Minvers, at Wheal Lea, at Wheal Kine, and at Endellion, in Cornwall; in Ayrshire, Scotland, at Hare Hill; in Borneo, in rhombic prisms half an inch long, terminating in two planes, and also massive; at the Carmen mine at Zacualpan in Mexico; at South Ham, Wolfe Co., Quebec; in California, Tulare Co., at Pass of San Amedio, with stibnite; with other antimony minerals in Sevier Co., Ark.

**222. STIBICONITE.** Antimony Ocher pt. (Syn. under Cervantite). Stibiconise *Beud.*, Tr., **2**, 616, 1832. Stiblith *Blum & Delffs*, J. pr. Ch., **40**, 318, 1847. Stibiconite *Brush*, Am. J. Sc., **34**, 207, 1862.

Massive, compact. Also as a powder and in crusts.

H. = 4–5·5. G. = 5·1–5·28. Luster pearly to earthy. Color pale yellow to yellowish white, reddish white.

**Comp.**—Probably $H_2Sb_2O_6$ or $Sb_2O_4.H_2O$ = Oxygen 19·9, antimony 74·5, water 5·6 = 100. Usually more or less impure.

**Anal.**—1, Blum & Delffs, l. c. 2, Santos, Chem. News, **36**, 167, 1877. 3, Sharples, Am. J. Sc., **20**, 423, 1880.

| | | O | Sb | As | $H_2O$ |
|---|---|---|---|---|---|
| 1. Goldkronach | G. = 5·28 | 19·54 | 75·83 | *tr.* | 4·63 = 100 |
| 2. Sevier Co., Arkansas | G. = 5·58 | 19·85 | [76·15] | — | 3·08 insol. 0·92 = 100 |
| 3. Sonora | G. = 5·07 | [20·0] | 75·0 | — | 5·0 |

**Pyr.**—In the closed tube gives off water, but does not fuse; on charcoal decrepitates, fuses with difficulty to a gray slag, and gives a white coating.

**Obs.**—From Goldkronach, Bavaria; with cervantite in Borneo, cf. Frenzel, Min. Mitth., 298, 1877. Probably from other localities of antimony ocher. Forms extensive deposits in Sonora, Mexico, usually massive. H. C. Lewis speaks of glassy octahedral crystals with G. = 4·9; he found 3·1 p. c. $H_2O$ (Amer. Nat., 608, 1882). Raimondi mentions a similar mineral derived from the alteration of stibnite from Chayramonte, Cajamarca, Peru.

VOLGERITE. Antimony Ocher pt. Hydrous Antimonic Acid. Volgerite *Dana*, Min., 142, 1854. Cumengite *Kenng.*, Min., 29, 1853.

Massive, or as a powder. Color white. Analysis: Cumenge, Ann. Mines, **20**, 80, 1851.

O 17·0 Sb 62·0 $H_2O$ 15·0 $Fe_2O_3$ 1·0 gangue 3·0 = 98·0

This corresponds perhaps to $Sb_2O_5.4H_2O$.

From the province of Constantine, Algeria. Volger remarks that white antimony ocher ($Sb_2O_5.5H_2O$) is a common result of the alteration of stibnite. Entwickl. Min., 77.

The following are uncertain minerals containing chiefly oxide of antimony.

RIVOTITE *Ducloux*, C. R., **78**, 1471, 1874.

Amorphous, compact, with a stony look. Fracture uneven. Fragile. H. = 3·5–4. G. = 3·55–3·62. Opaque. Color yellowish green to grayish green. Streak grayish green. Analysis.—Ducloux:

$Sb_2O_5$ 42·00 $Ag_2O$ 1·18 CuO 39·50 $CO_2$ 21·00 CaO *tr.* = 103·68

Occurs in small irregular masses disseminated through a yellowish white limestone, on the west side of the Sierra del Cadi, province of Lerida. Named after Prof. Rivot of the École des Mines, Paris

STIBIANITE *E. Goldsmith*, Proc. Ac. Philad., 154, 1878. An alteration product of stibnite, from Victoria, Australia. Massive, porous. H. = 5. G. = 3·67. Color reddish yellow, of powder pale yellow. Luster dull. Analysis by W. H. Dougherty. l. c.: $Sb_2O_5$ 81·21, $H_2O$ 4·46, gangue 13·55. After deduction of the impurities: $Sb_2O_5$ 94·79, $H_2O$ 5·21 = 100, which, if the results could be trusted, would correspond to the formula $Sb_2O_5.H_2O$.

**Stibioferrite** *E. Goldsmith,* Proc. Ac. Philad., p. 366, 1873. Amorphous. Brittle, fracture uneven to conchoidal. H. = 4. G. = 3·598. Luster slightly resinous. Color yellow to brownish yellow. Streak dull yellow. Soluble in hydrochloric acid. Analysis:

$Sb_2O_5$ 42·96 $Fe_2O_3$ 3·85 $H_2O$ 15·26 $SiO_2$ 8·84 loss 1·09 = 100

Occurs as a coating, sometimes ¼ inch thick, on stibnite from Santa Clara Co., Cal.

**Partzite** *A. Arents,* Am. J. Sc., **43**, 362, 1867. Apparently a hydrous oxide of antimony mixed with various metallic oxides, as pronounced by Blake (ib., **44**, 119). It varies in color from yellowish green to blackish green and black; has G. = 3·8; H. = 3–4; and an even conchoidal fracture.

An analysis afforded Arents: $Sb_2O_3$ 47·65, $Cu_2O$ 32·11, $Ag_2O$ 6·12, PbO 2·01, FeO 2·33, $H_2O$ 8·29 = 98·51. It occurs in the Blind Spring Mts., Mono Co., California, with argentiferous galena, and antimonial ores of lead and silver, from whose decomposition it has probably proceeded. Named for Dr. A. F. W. Partz.

A related mineral occurs at the mine of San Lorenzo, province of Huaylas, and mine des Italiens, province of Cajatambo, Peru, *Raimondi,* Min. Pérou, pp. 83, 86, 87, 1878.

**Stetefeldtite** *E. Riotte,* B. H. Ztg., **26**, 253, 1867. Appears to be very similar to partzite. It occurs massive; blackish and brown in color; H. = 3·5–4·5; G. = 4·12–4·24, with a shining streak. Stetefeldt (ib., p. 281) found as a mean of two analyses: $Sb_2O_4$ 43·77, S 4·7, Ag 23·74, Cu 12·78, Fe 1·82, $H_2O$ 7·9; and thence deduces $Sb_2O_5$ 46·47, S 4·59, Ag 23·23, Cu 2·27, FeO 2·41, CuO 13·28, $H_2O$ 7·75 = 100.

It comes from southeastern Nevada, in the Empire district; also in the Philadelphia district. Named for the mining engineer, Ch. Stetefeldt.

An antimonite of copper, resembling stetefeldtite, has been described by Domeyko as occurring at the Potochi copper mine, near Huancavelica, Peru. It is amorphous, compact. Fracture smooth or uneven, in parts coarsely granular. Color black or greenish black. Streak yellowish green. Luster weakly resinous. An analysis on the purest material obtainable (though still mixed with some sub-sulphate of copper) gave: $Sb_2O_4$ 32·93, CuO 32·27, $Fe_2O_3$ 11·14, ZnO 0·50, $SO_3$ 1·00, $H_2O$ (loss at low redness) 18·53, insoluble 1·57 = 96·94. B.B. infusible. Dissolves readily in hydrochloric acid. Domeyko regards the mineral as probably having come from the decomposition of chalcostibite. 3d Appendix Min. Chili, 1871.

**223. WATER.** Wasser *Germ.* Vatten *Swed.* Eau *Fr.* Acqua *Ital.* Agua *Span.*

Water exists in three states: (1) a solid, Ice, at or below 0° C.; (2) a liquid, Water proper, between 0° and 100°; (3) a gas, Steam and Aqueous Vapor, the former at 100° C. under a pressure of 760 mm., or at higher or lower temperatures with requisite increase or decrease of pressure, the latter in the atmosphere at all temperatures.

**ICE.** Eis *Germ.* Is *Swed.* Glace *Fr.* Ghiâccio *Ital.*

Hexagonal; probably hemimorphic. Axis $\dot{c}$ = 1·4026 approx.; $0001 \wedge 10\bar{1}1 = 58° \ 18\frac{1}{2}'$ Nordenskiöld.

**Forms**[1]: *c* (0001, *O*), *m* ($10\bar{1}0$. *I*); *r* ($10\bar{1}2$, ½), *s* ($10\bar{1}1$, 1), *t* ($40\bar{4}1$, 4).

Angles: *cr* = *39°, *cs* = 58° 18½′, *ct* = 81° 13½′, *rr′* = 36° 41′, *ss′* = 50° 21½′, *tt′* = 59° 14′.

Distinct faces rare. Usually, as snow crystals, in compound six-rayed stellate forms of great variety and delicacy; occasionally as hail[3], with hexagonal crystals projecting from a solid nucleus, or rarely in distinct quartzoids. Also granular and compact massive.

Brittle at low temperatures, but somewhat less so near the melting-point. H. = 1·5. G. = 0·9167 Bunsen[2]. Fracture conchoidal. Luster vitreous. Colorless to white when pure, but in thick layers pale blue. Transparent. Optically uniaxial, positive. Refractive indices, Reusch[4]:

$\omega_r = 1·30598$ $\epsilon_r = 1·30734$ $\omega_{gr} = 1·3120$ $\epsilon_{gr} = 1·3136$ $\omega_v = 1·317$ $\epsilon_v = 1·321$

Also Meyer[5]:

$\omega_r = 1·2970$ Li at $-8°$C. $\omega_y = 1·3090$ Na at $-8°$ $\omega_{gr} = 1·3107$ Tl at $- 3·8°$
$\epsilon_r = 1·3037$ " " $\epsilon_y = 1·3133$ " " $\epsilon_{gr} = 1·3163$ " "

**Comp.**—$H_2O$ = Oxygen 88·9, hydrogen 11·1 = 100.

**Obs.**—Formed as a coating over ponds, lakes, rivers, etc., at low temperatures; also direct from water vapor in the atmosphere as snow, often in crystals of great beauty and variety of form; also as frost, hail, etc. Forming permanent fields of snow at definite altitudes, depending upon the latitude; under favorable conditions changed into solid ice and descending as glaciers far below the snow-line; also, when the latter reach the sea, forming icebergs carried by ocean currents into lower latitudes.

**Ref.**—[1] Öf. Ak. Stockh., **17**, 439, 1860, or Pogg., **114**, 612, 1861; the measurements are only approximate, and but little weight can be given to them; forms apparently orthorhombic or tetragonal were also observed. Oxydulated copper. Ziguéline *Beud.*, Tr., **2**, 713, 1832. Ruberite *Chapm.*, Pract. Min., 63, 1843. Cuprit *Haid.*, Handb, 548, 1845. Ruby copper.

Ziegelerz = Tile Ore; Kupferlebererz; Hepatinerz. Ziguelina *Ital.*

Haarförmiges Rothkupfererz. Cuivre oxidulé capillaire, *H.* Kupferblüthe *Hausm.* Capillary Red Oxide of Copper. Chalkotrichit *Glock* , Grundr., 369, 1839. Plush Copper Ore.

Isometric; with trapezohedral hemihedrism. Observed forms[1]:

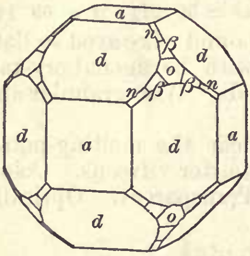
$a$ (100, $i$-$i$) $o$ (111, 1) $e$ (210, $i$-2) $q$ (331, 3) $\delta$ (533, $\frac{5}{3}$-$\frac{5}{3}$)[3] $s$ (321, 3-$\frac{3}{2}$)
$d$ (110, $i$) $\eta$ (510, $i$-5) $p$ (221, 2) $n$ (211, 2-2) $\beta$ (322, $\frac{3}{2}$-$\frac{3}{2}$)[2]

Also $x$ (986, $\frac{3}{2}$-$\frac{9}{8}$) developed as a trapezohedral hemihedral form, f. 3, Miers[4].

Commonly in octahedrons; also in cubes and dodecahedrons, often highly modified. Sometimes cubes lengthened into capillary forms. Also massive, granular; sometimes earthy.

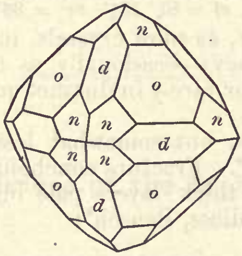
Cleavage: $o$ interrupted; rarely $a$[4]. Fracture conchoidal, uneven. Brittle. H. = 3·5–4. G. = 5·85–6·15; 5·992, Haid. Luster adamantine or submetallic to earthy. Color red, of various shades, particularly cochineal-red, sometimes almost black; occasionally crimson-red by transmitted light. Streak several shades of brownish red, shining. Subtransparent to subtranslucent. Refractive index high, $n_r$ = 2·849 Fizeau[5].

1.



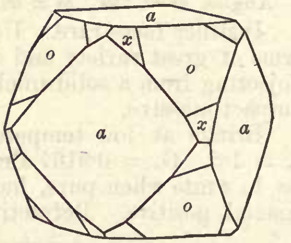
Arizona.

2.



Gov't Perm, Kk.

3.



Cornwall, Miers[4].

**Var.**—1. *Ordinary.* (*a*) Crystallized; commonly in octahedrons, dodecahedrons, cubes, and intermediate forms; the crystals often with a crust of malachite; (*b*) massive.

2. *Capillary; Chalcotrichite.* Plush copper Ore. In capillary or acicular crystallizations, which are cubes elongated in the direction of the octahedral axis (Knop, Jb. Min., 521, 1861).

3. *Earthy; Tile Ore,* Ziegelerz *Germ.* Brick-red or reddish brown and earthy, often mixed with red oxide of iron; sometimes nearly black. The *hepatinerz*, or *liver ore*, of Breithaupt has a liver-brown color. Von Bibra found (J. pr. Ch., **96**, 203, 1865) the tile-ore of Algodon bay, Bolivia, to be a mixture of atacamite, cuprite, hematite, and other earthy material.

**Comp.**—Cuprous oxide, $Cu_2O$ = Oxygen 11·2, copper 88·8 = 100.

**Pyr., etc.**—Unaltered in the closed tube. B.B. in the forceps fuses and colors the flame emerald-green; if previously moistened with hydrochloric acid, the color imparted to the flame is momentarily azure-blue from chloride of copper. On charcoal first blackens, then fuses, and is reduced to metallic copper. With the fluxes gives reactions for copper. Soluble in concentrated hydrochloric acid, and a strong solution when cooled and diluted with cold water yields a heavy, white precipitate of subchloride of copper.

**Obs.**—Occurs at Kamsdorf and Saalfeld in Thuringia; at Les Capanne Vecchie in Tuscany; on Elba, in cubes; in Cornwall, in fine translucent crystals with native copper and quartz, at Wheal Gorland and other Cornish mines; in Devonshire near Tavistock; in isolated crystals, sometimes an inch in diameter, in lithomarge, at Chessy, near Lyons, which are generally coated with, or entirely altered to, malachite; at Ekaterinburg in the Ural; in South Australia; also abundant in Chili, Peru, Bolivia; very fine crystals from Andacollo near Coquimbo.

In the U. S. it has been observed at Schuyler's, Somerville, and Flemington copper mines, N. J., crystallized and massive, associated with chrysocolla and native copper; also near New Brunswick, N. J., in red shale; 2 m. from Ladenton, Rockland Co., N. Y., with green malachite in trap; in soft earthy form in sandstone at Cheshire near New Haven, Conn.; at Cornwall, Lebanon Co., Pa.; in the Lake Superior region; at the copper mines in St. Genevieve Co., Mo. With malachite, limonite, etc., at the Copper Queen mine, Bisbee, Arizona, sometimes in fine crystals; beautiful *chalcotrichite* at Morenci; at Clifton, Graham Co., in crystals, and massive.

Named *cuprite* by Haidinger from the Latin *cuprum*, copper.

**Artif.**—An occasional furnace-product. Cf. Arzruni, Zs. Kr., **18**, 58, 1890. Also a recent formation on buried copper coins, bronze utensils, etc., cf. Fletcher, Min. Mag., **7**, 187, 1887.

**Alt.**—A deoxidation of cuprite sometimes takes place, producing native copper. It also becomes carbonated and green, by means of carbonated waters, changing to malachite or azurite; or through a silicate in solution it is changed to chrysocolla; or by taking oxygen it becomes melaconite. Limonite occurs as a pseudomorph by substitution after cuprite.

**Ref.**—[1] Cf. Mlr., Min., 223, 1852; Schrauf, Atlas, L. An early paper illustrated with 9 plates and 108 figures is given by Phillips in Trans. G. Soc. London, 1, 23, 1811. [2] Schrauf, Liskeard, Cornwall, Min. Mitth., 106, 1871. [3] Miers, Wheal Phœnix, Min. Mag., 8, 207, 1889. [4] Phil. Mag., 18, 127, 1884. [5] Quoted by Dx., N. R., 10, 1867.

HYDROCUPRITE *Genth*, Report Min. Penn., 46, 1875. From Cornwall, Lebanon Co., Penn. Is perhaps a hydrated cuprite. Amorphous, orange-yellow to orange-red; forms very thin coatings, sometimes rag-like, upon magnetite. A similar substance has been noted with cuprite at Schapbach, Baden (Sandb.).

## Periclase Group. RO. Isometric.

**225. PERICLASE.** Periclasia *Scacchi*, Mem. Min., Naples, 1841. Periklas *Germ.* Periclasite.

Isometric. In cubes or octahedrons. Also in grains.

Cleavage: cubic, perfect; octahedral less distinct. H. = nearly 6. G. = 3·674, Vesuvius; 3·90, Nordmark. Colorless to grayish, and dark green. Transparent to translucent.

**Comp.**—Magnesia, MgO = Oxygen 40, magnesium 60 = 100. Iron or manganese may be also present.

**Anal.**—1, 2, Damour, Ann. Mines, **3**, 381, 1843, and Bull. Soc. G. Fr., **6**, 311, 1849; also earlier, Scc., l. c. and 5th Ed., p. 134. 3, A. Sjögren, G. För. Förh., **9**, 526, 1887. 4, G. Lindström, ibid.

| | MgO | FeO | MnO | ZnO | ign. | |
|---|---|---|---|---|---|---|
| 1. Vesuvius G. = 3·674 | 93·86 | 5·97 | — | — | — | = 99·83 |
| 2. " | 93·38 | 6·01 | — | — | — | = 99·39 |
| 3. Nordmark G. = 3·90 | $\frac{3}{3}$ 86·38 | 0·46 | 8·27 | 1·98 | 1·45 | = 98·54 |
| 4. " | 87·38 | 0·19 | 9·00 | 2·52[a] | — | = 99·09 |

[a] Incl. some MnO.

**Pyr., etc.**—B.B. unaltered and infusible; the manganesian variety becomes dark colored. With cobalt solution after long blowing assumes a faint flesh-red color. The pulverized mineral shows an alkaline reaction when moistened, and dissolves in mineral acids without effervescence.

**Obs.**—Occurs disseminated through ejected masses of a white limestone, and in spots of small clustered crystals, on Mt. Somma, sometimes with forsterite and earthy magnesite. At the Kitteln manganese mine, Nordmark, Wermland, Sweden, in small grains in a dolomitic limestone together with hausmannite; the grains are surrounded by a more or less distinct zone of brucite formed by alteration.

Peculiar pseudomorphs of serpentine (and in part of dolomite), showing a structure apparently corresponding to a highly perfect cubic cleavage, have been observed at the Tilly Foster iron mine at Brewster, N. Y. (J. D. D., Am. J. Sc., 8, 375, 1874). The nature of the original mineral is in doubt; Tschermak has suggested that it may have been periclase.

Named from *περί*, *about*, and *κλάσις*, *fracture*, in allusion to the cleavage.

**Artif.**—Formed in crystals of a cubo-octahedral form by making lime to act at a high temperature on magnesium borate (Ebelmen); by the action of hydrochloric acid gas on magnesia (Deville); by the action of magnesium chloride on lime (Daubrée).

**226. MANGANOSITE.** Manganosit *Blomstrand*, G. För. Förh., **2**, 179, 1874.

Isometric. In minute octahedrons, with *d* and rarely *a*.

Cleavage: cubic. H. = 5–6. G. = 5·18. Luster vitreous. Color emerald green when fresh, becoming black on exposure. Isotropic.

**Comp.**—Manganese protoxide, MnO = Oxygen 22·6, manganese 77·4 = 100.

**Anal.**—Blomstrand, 9 För. Föhr., **2**, 182, 1874.

| | MnO | FeO | MgO | CaO | |
|---|---|---|---|---|---|
| $\frac{3}{2}$ | 98·04 | 0·42 | 1·71 | 0·16 | = 100·33 |

**Pyr., etc.**—B.B. blackens, without sensibly fusing. Dissolves with difficulty in strong nitric acid, forming a colorless solution. Reacts for manganese with the fluxes.

**Obs.**—Occurs with pyrochroite and manganite, in a manganiferous dolomite (anal.: $CaCO_3$ 56·47, $MnCO_3$ 30·10, $MgCO_3$ 13·56, $FeCO_3$ 0·18 = 100·31, Blomstrand) at Långban, Wermland, Sweden; also in calcite, brucite, or dolomite, with hausmannite, pyrochroite, garnet, etc., at the Moss mine, Nordmark, Wermland, Sweden.

**227. BUNSENITE.** Nickeloxydul *C. Bergemann*, J. pr. Ch., **75**, 243, 1858. Bunsenite *Dana*, Min., 134, 1868.

Isometric. In minute octahedrons, sometimes having truncated edges.

H. = 5·5. G. = 6·398. Luster vitreous. Color pistachio-green. Streak brownish black. Translucent. Artificial crystals observed in slags have a metallic luster, and brownish black color.

**Comp.**—Nickel protoxide, NiO = Oxygen 21·5, nickel 78·5 = 100.

**Obs.**—Occurs in cavities with other nickel ores, and ores of uranium, at Johanngeorgenstadt. Named after Prof. R. W. Bunsen of Heidelberg (b. 1811), who observed long since artificial crystals of this nickel oxide.

---

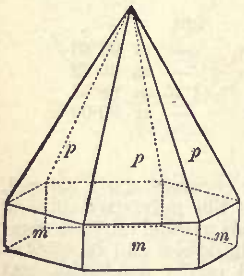
**228. ZINCITE.** Red Oxide of Zinc *A. Bruce*, Bruce's Min. J., **1**, No. 2, 96, 1810. Zinkoxyd, Rothzinkerz, *Germ.* Zinc oxydé *Fr.* Red Zink Ore. Zinkit *Haid.*, Handb., 548, 1845. Spartalite *B. & M.*, 218, 1852. Sterlingite F. Alger, Min., 565, 1844.

Hexagonal; hemimorphic. Axis $\dot{c} = 1·6219$; $0001 \wedge 10\bar{1}1 =$ *61 °54′ Rinne[1].

**Forms**[2]: *c* (0001, *O*), *m* ($10\bar{1}0$, *I*), *p* ($10\bar{1}1$, 1). Also on artif. cryst.[3]: *a* ($11\bar{2}0$, *i*-2), *s* ($10\bar{1}3$, $\frac{1}{3}$), *ρ* ($20\bar{2}5$, $\frac{2}{5}$), *n* ($10\bar{1}2$, $\frac{1}{2}$), *ω* ($30\bar{3}5$, $\frac{3}{5}$), *q* ($20\bar{2}3$, $\frac{2}{3}$), *ξ* ($80\bar{8}9$, $\frac{8}{9}$)[5] as tw. pl., *v* ($80\bar{8}5$, $\frac{8}{5}$), *y* ($20\bar{2}1$, 2); *d* ($11\bar{2}1$, 2-2)[5]; *μ* ($21\bar{3}3$, 1-$\frac{3}{2}$)[4].

Angles: *pp′* = 52° 21′, *cρ* = 36° 50′, *cω* = 48° 20′, *cv* = 71° 33′, *cd* = 72° 52′.

1.



Natural crystals rare, hemimorphic (f. 1); usually foliated massive, or in coarse particles and grains; also with granular structure.

Artif. crystals generally prismatic (*m*) or quartzoids (*p*) with *c*; hemimorphic in habit (as also shown by etching-figures, Rinne, l. c.), like wurtzite, greenockite, iodyrite, with which species it is homœomorphous. Also twinned, with *ξ* as tw. pl., Rath[6]; also with *c* tw. pl. and comp.-face, Rinne.

Cleavage: *c* perfect; prismatic, sometimes distinct. Fracture subconchoidal. Brittle. H. = 4–4·5. G. = 5·43–5·7; 5·684, cryst., Blake. Luster subadamantine. Streak orange-yellow. Color deep red, also orange-yellow. Translucent to subtranslucent. Optically +.

**Comp.**—Zinc oxide, ZnO = Oxygen 19·7, zinc 80·3 = 100. Manganese protoxide is sometimes present.

**Anal.**—Stone, Sch. Mines, Q., **8**, 149, 1887. See also 5th Ed., p. 135.

| | | ZnO | MnO | $Fe_2O_3$ |
|---|---|---|---|---|
| 1. Sterling Hill | G. = 5·531 | 93·28 | 6·50 | 0·44 = 100·22 |
| 2. " " | G. = 5·507 | 94·30 | 5·54 | 0·36 = 100·20 |

**Pyr., etc.**—Heated in the closed tube blackens, but on cooling resumes the original color. B.B. infusible; with the fluxes, on the platinum wire, gives reactions for manganese, and on charcoal in R.F. gives a coating of zinc oxide, yellow while hot, and white on cooling. The coating, moistened with cobalt solution and treated in O.F., assumes a green color. Soluble in acids without effervescence. On exposure to the air it suffers a partial decomposition at the surface, and becomes invested with a white coating of zinc carbonate.

**Obs.**—Occurs with franklinite and willemite, at Sterling Hill near Ogdensburg, and at Mine Hill, Franklin Furnace, Sussex Co., N. J., sometimes in lamellar masses in pink calcite. It was first noticed, described, and analyzed by Dr. Bruce. Has been reported as forming pseudomorphs after sphalerite at Schneeberg.

**Artif.**—Mitscherlich has observed minute six-sided prisms in the iron-furnaces of Königshütte, in Silesia. Similar crystals have been met with in the zinc furnace~~s near~~ Siegen; also in the furnaces and roast-heaps at the New Jersey zinc mines; surface drusy, color white to amber-yellow (Am. J. Sc., **13**, 417, 1852); in hexagonal prisms in the zinc furnaces at Bethlehem, Pa., and Newark, N. J.; by L. Stadtmüller at the iron furnace of Van Deusenville, Mass.; also at other furnaces in Europe and America. Cf. also ref. below and Gorgeu, Bull. Soc. Min., **10**, 36, 1887.

**Ref.**—[1]Artif. cryst. from Lerbach in the Harz, Jb. Min., **2**, 164, 1884; Rose gives $pp' =$ 52° 17′ to 52° 20′, Kr.-Chem. Min., 64, 1852. [2]E. S. D., Franklin Furnace, N. J., Am. J. Sc., **32**, 389, 1886. [3]Cf. Hausm. for a reconciliation of earlier observations, Handb., **2**, 199, 1847. [Stud., Gött. Ver. Bergm. Freunde, **5**, 215]; some of these planes are doubtful; also Greim, Ber. Oberhess. Ges., **24**, 1886. [4]Rath, Pogg., **122**, 406, 1864. [5]Busz, artif. cryst., Zs. Kr., **15**, 621, 1889. [6]Id., Pogg., **144**, 580, 1871; cf. Lévy, Ann. Mines, **4**, 516, 1843. See p. 1052.

CALCOZINCITE *Shepard*, Contrib. Min., Amherst, 1876, Am. J. Sc., **12**, 231, 1876. A substance from Sterling Hill, New Jersey, described as having a fine granular to columnar structure, light orange-yellow color. It is probably a mechanical mixture of zincite and calcite, as an analysis indicates.

**229. MASSICOT.** *Huot*, Min., 346, 1841. Massicottite *A. D'Achiardi* I Metalli, **1**, 221, 1883. Lead ocher, Plumbic ocher, Lead oxide. Bleiglätte, Bleioxyd, *Germ.* Chrysitin *Weisbach*, Synops. Min., 54, 1875. Plomb oxidé jaune *Fr.* Piombo ossidato *Ital.* Litarjirio nativo *Span.*, Domeyko, Min. Chili, 1879.

Massive; structure scaly crystalline or earthy.

H. = 2. G. = 8·0; 7·83–7·98, Mexico, Pugh; 9·2–9·36 when pure. Luster dull. Color between sulphur- and orpiment-yellow, sometimes reddish. Streak lighter than the color. Opaque. Does not soil.

Artif. cryst. early described as isometric, later shown to be orthorhombic; crystals thin tabular ∥ *a*, with *a* (100), *c* (001), *d* (*h*0*l*), *r* (111), *s* (455), *t* (233), and two other undetermined brachypyramids *q*, *v* Nd.[1] See also Mitsch.[2], who describes rhombic pyramids, also Grail.[3], Rg.[4], and Lüdecke[5], who mention tetragonal forms; also Michel[6], who finds them optically negative.

**Comp.**—Lead monoxide, PbO = Oxygen 7·2, lead 92·8 = 100. The natural mineral is more or less impure.

Analyses, see 5th Ed., p. 136.

**Pyr., etc.**—B.B. fuses readily to a yellow glass, and on charcoal is easily reduced to metallic lead.

**Obs.**—It is said to occur at Badenweiler in Baden, in quartz. Gerolt states that it has been ejected from the volcanoes of Popocatapetl and Jztaccituall, in Mexico. It is found in many places in the provinces of Chihuahua and Cohahuila in considerable quantities, having been collected along the streams between Ceralvo and Monterey, being supposed to come from the range of mountains running nearly north of Monterey. The specimens (often 2 or more cubic inches in size) are between orpiment- and sulphur-yellow in color, and glisten like a granular mica of a nearly golden color. The natural surface is slightly crystalline and shining, and when broken it shows a scaly texture.

Occurs also at Austin's mines, Wythe Co., Va.

**Artif.**—Artificial crystals have been obtained among furnace-products and by direct chemical methods, as well as from fusion. The yellow powder (PbO) obtained by heating lead in a current of air is called *massicot;* if, however, the heat is sufficient to fuse the oxide, the product, crystallizing usually in yellowish red scales, is called *litharge.*

**Ref.**—[1] Pogg., **114**, 619, 1861. [2] Ber. Ak. Berlin, 11, 1840. [3] Ber. Ak. Wien, **28**, 282, 1858. [4] Kr. Ch., **1**, 181, 1881. [5] Zs. Kr., **8**, 82, 1883. [6] Bull. Soc. Min., **13**, 56, 1890.

**230. TENORITE.** Kupferschwärze *Wern.*, Bergm. J., 1789. Melaconite *Huot*, Min., 326, 1841. Tenorite *Semmola*, Opere Minori, 45, Napoli, 1841, Bull. G. Fr., **13**, 206, 1841–42. Melaconisa *A. Scacchi*, Distrib. Sist. Min., 40, Napoli, 1842. Melaconite *Dana*, Min., 518, 1850. Black copper; Black Oxide of Copper. Kupferoxyd *Germ.* Cuivre oxydé noir *Fr.* Nero rame *Ital.* Cobre negro *Span.*

Monoclinic (or Triclinic). Axes: $\grave{a} : \bar{b} : \acute{c} = 1·4902 : 1 : 1·3604$; $\beta = 80° 28'$ = 001 ∧ 100 Maskelyne[1].

100 ∧ 110 = 55° 46′, 001 ∧ 101 = 38° $1\frac{2}{3}$′, 001 ∧ 011 = 53° 18′.

**Forms:** *a* (100, *i*-*ī*), *c* (001, *O*); *x* (601, – 6-*ī*), *q* (011, 1-*ĭ*), *u* (111, – 1), *o* ($\bar{1}$11, 1), *z* (611, – 6-$\bar{6}$).

Angles: *qq'* = 106° 36', *uu'* = 85° 6', *oo'* = 94° 38', *au* = 57° 4', *aq* = 84° 19', *a'o* = 65° 50.

The axial ratio of Maskelyne given above (he gives no angles) was deduced by him from melaconite crystals from Cornwall. Artif. crystals were described by Jenzsch as orthorhombic, but his results agree better with those of Maskelyne (Scacchi, Kalkowsky). Tenorite crystals from Vesuvius have been described by Scacchi, and later by Kalkowsky, who makes them triclinic on optical grounds. Supposed isometric crystals of melaconite from Lake Superior were perhaps pseudomorphs.

Twins: tw. pl. *a*. Often in thin shining flexible scales. Earthy; massive; pulverulent.

Cleavage: *c* easy, also *u* (111) Mask. Fracture conchoidal to uneven. H. = 3–4. G. = 5·825 cryst., Mask.; 6·25, massive, Whitney; 5·952, id., Joy. Luster metallic, and color steel- or iron-gray when in thin scales; dull and earthy, with a black or grayish black color, and ordinarily soiling the fingers when massive or pulverulent.

**Var.**—1. *Tenorite.* In minute scales with metallic luster, found at Vesuvius.

2. *Melaconite.* Earthy black massive.

**Comp.**—Cupric oxide, CuO = Oxygen 20·2, copper 79·8 = 100.

**Pyr., etc.**—B.B. in O.F. infusible; other reactions as for cuprite, p. 206. Soluble in hydrochloric and nitric acids.

**Obs.**—Found on lava at Vesuvius in scales from a twentieth to a third of an inch across, often hexagonal and sometimes triangular; and also pulverulent. Common in the earthy form about copper mines, as a result of the decomposition of chalcopyrite and other copper ores. Abundant thus at the Ducktown mines in Tennessee, and also formerly at Copper Harbor, Keweenaw Point, L. Superior. Named after Sr. Tenore, President of the Naples Academy.

**Ref.**—[1] Brit. Assoc., 33, 1865. Jenzsch, Pogg., **107**, 647, 1859. Kalkowsky, Zs. Kr., 3, 279, 1879. On paramelaconite, see p. 1043.

MARCYLITE *Shepard*, Marcy's Expl. Red River, 135, 1854, Shep. Min., 405, 1857. An uncertain mixture from the Red River, near the Wachita Mts., Arkansas. Supposed to consist of oxide of copper, sulphide of copper, with water. It is evidently a result of the alteration of a copper sulphide. See 5th Ed., p. 137.

A similar mixture from Peru is mentioned by Raimondi, Min. Pérou, 137, 1878.

LIME. Calcium oxide. Calce *Scacchi.*

Found at Vesuvius enveloped in the lava of 1631, as a result of the alteration of calcium carbonate.

PALLADINITE *Adam*, Tabl. Min., 82, 1869. Palladium oxide, PdO; credited to Lampadius.

---

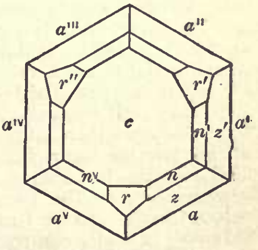
Twins: tw. pl. *r*; sometimes penetration-twins; often polysynthetic, and thus producing a laminated structure. Crystals often rough and rounded, especially if large. Planes in zone *ca* deeply striated horizontally; *c* striated ‖ edge *c/r*, or divided into sectors by lines radiating from center normal to edges *c/a*. Also massive, with nearly rectangular parting or pseudo-cleavage; granular, coarse or fine.

Parting: *c*, sometimes perfect, but interrupted; also *r* due to twinning, often prominent. Fracture uneven to conchoidal. Brittle, when compact very tough. H. = 9. G. = 3·95–4·10. Luster adamantine to vitreous; on *c* sometimes pearly. Occasionally showing asterism. Color blue, red, yellow, brown, gray, and nearly white; streak uncolored. Pleochroic in deeply colored varieties. Transparent to translucent.

7.



Ilmen Mts., Kk.

Normally uniaxial, negative; sapphire $\omega_r = 1·7676$ to $1·7682$ and $\epsilon_r = 1·7594$

to 1·7598; ruby $\omega = 1·7675$, $\epsilon = 1·7592$, Dx.[7] Often abnormally biaxial[8]. Phosphorescent with a rich red color, and yielding a double crimson line (at $\lambda = 6937$, 6942) in the spectroscope (Crookes).

**Var.**—There are three subdivisions of the species prominently recognized in the arts, and until early in this century regarded as distinct species; but which actually differ only in purity and state of crystallization or structure. Haüy first (in 1805) formally united them under the name here accepted for the species, though the fact that adamantine spar and sapphire were alike in crystallization did not escape the early crystallographer Romé de Lisle, and led him to suggest their identity.

VAR. 1. SAPPHIRE, RUBY.—Includes the purer kinds of fine colors, transparent to translucent, useful as gems. Stones are named according to their colors: *Sapphire* blue; true *Ruby*, or *Oriental Ruby*, red; *O. Topas*, yellow; *O. Emerald*, green; *O. Amethyst*, purple. A variety having a stellate opalescence when viewed in the direction of the vertical axis of the crystal, is the *Asteriated* Sapphire or Star Sapphire (*Asteria* of Pliny). The ruby sapphire was probably included under the *ἄνθραξ* of Theophrastus, and the *Carbunculus* and *Lychnis* of Pliny. The blue sapphire (Ceylon) was called Salamstein by Werner.

*Barklyite* is a more or less opaque magenta-colored ruby from Victoria, cf. Liversidge, Min. N. S. W., 198, 1888. *Chlorsapphir* is a deep green variety occurring in bombs of a "sanidine-gneiss" enclosed in an ancient trachytic tufa at Königswinter on the Rhine, cf. Polig, Ber. nied. Ges., May 7, 1888.

2. CORUNDUM.—Includes the kinds of dark or dull colors and not transparent, colors light blue to gray, brown, and black. The original adamantine spar from India has a dark grayish smoky-brown tint, but greenish or bluish by transmitted light, when translucent, and either in distinct crystals, often large, or cleavable-massive. It is ground and used as a polishing material, and being purer, is superior in this respect to emery. It was thus employed in ancient times, both in India and Europe. The "Armenian stone" is supposed by King to have been corundum rather than emery.

3. EMERY. Schmirgel *Germ.*—Includes granular corundum, of black or grayish black color, and contains magnetite or hematite intimately mixed. Sometimes associated with iron spinel or hercynite. Feels and looks much like a black fine-grained iron ore, which it was long considered to be. There are gradations from the evenly fine grained emery to kinds in which the corundum is in distinct crystals. This last is the case with part of that at Chester, Massachusetts. The specific gravity varies rather widely, G. = 3·75–4·31 Smith.

**Comp.**—Alumina, $Al_2O_3$ = Oxygen 47·1, aluminium 52·9 = 100. The crystallized varieties are essentially pure; analyses of emery show more or less impurity, chiefly magnetite.

For analyses, etc., see J. L. Smith, Am. J. Sc., **10**, 354, 1850, **11**, 53, 1851, **42**, 83, 1866, and 5th Ed., p. 139.

**Pyr., etc.**—B.B. unaltered; slowly dissolved in borax and salt of phosphorus to a clear glass, which is colorless when free from iron; not acted upon by soda. The finely pulverized mineral, after long heating with cobalt solution, gives a beautiful blue color. Not acted upon by acids, but converted into a soluble compound by fusion with potassium bisulphate.

**Obs.**—Usually occurs in crystalline rocks, as granular limestone or dolomite, gneiss, granite, mica slate, chlorite slate. The associated minerals often include some species of the chlorite group, as prochlorite, corundophilite, margarite, also tourmaline, spinel, cyanite, diaspore, and a series of aluminous minerals, in part produced from its alteration. Occasionally found in ejected masses enclosed in younger volcanic rocks, as at Königswinter, Niedermendig, etc. Rarely observed as a contact-mineral. The fine sapphires are usually obtained from the beds of rivers, either in modified hexagonal prisms or in rolled masses, accompanied by grains of magnetite, and several kinds of gems, as spinel, etc. The emery of Asia Minor, Dr. Smith states, occurs in granular limestone.

The best rubies come from the mines in Upper Burma, north of Mandalay, in an area covering 25 to 30 square miles, of which Mogok is the center. Also found in the marble hills of Sagyin, 16 miles north of Mandalay. The rubies occur *in situ* in crystalline limestone, also in the soil of the hillsides and in gem-bearing gravel. All the crystallized varieties of the species occur here; the spinel ruby is a common associate. A ruby weighing 304 carats is said to have been found here in 1890. Rubies and sapphires have also been reported from other localities, and the massive varieties are common especially in the crystalline rocks of southern India. Ruby mines have also been worked at Jagdalak, 32 miles east of Kábul, Afghánistán. Some fine sapphires were obtained in 1882 from the Zánskár range of the Kashmir Himalayas near the village Machél in Pádar, and since then mining has been carried on there with some success (Mallet, Min. India; La Touche, Rec. G. Surv. India, **23**, 59, 1890). Blue sapphires are brought from Ceylon, often as rolled pebbles, but also as well-preserved crystals. Corundum occurs in the Carnatic on the Malabar coast, on the Chantibun hills in Siam, and elsewhere in the East Indies; also near Canton, China. At St. Gothard, it occurs of a red or blue tinge in dolomite, and near Mozzo in Piedmont, in white compact feldspar. Adamantine spar is met with in large coarse, hexagonal pyramids in Gellivara, Sweden.

Emery is found in large boulders at Naxos, Nicaria, and Samos of the Grecian islands; also in Asia Minor, 12 m. E. of Ephesus, near Gumuch-dagh, where it was discovered *in situ* by Dr. J. Lawrence Smith, associated with margarite, chloritoid, pyrite, calcite, etc.; and also at Kulah, Adula, and Manser, the last 24 m. N. of Smyrna; also with the nacrite (?) of Cumberland, England. Other localities are in Bohemia, near Petschau; in the Ural, near Ekaterinburg; and in the Ilmen mountains, not far from Miask; in the gold-washings northeast of Zlatoust as small crystals (called *soimonite* after Senator Soimonov) in barsovite (Kk. Min. Russl., **1**, 30, **2**, 80). Corundum, sapphires, and less often rubies occur in rolled pebbles in the diamond gravels on the Cudgegong river, at Mudgee and other points in New South Wales.

In N. America, in *Maine*, at Greenwood, in cryst. in mica schist, with beryl, zircon, lepidolite, rare. In *Massachusetts*, at Chester, corundum and emery in a large vein, consisting mainly of emery and magnetite, associated with diaspore, ripidolite, margarite, etc.; the corundum occasionally in blue pyramidal crystals. In *Connecticut*, at W. Farms, near Litchfield, in pale blue crystals; at Norwich, with sillimanite, rare. In *New York*, at Warwick, bluish and pink, with spinel, and often in its cavities; Amity, white, blue, reddish crystals, with spinel and rutile in gran. limestone. Emery with magnetite and green spinel (hercynite) in Westchester Co. in Cortlandt township, near Cruger's Station, and elsewhere (Am. J. Sc., **33**, 194, 1887). In *New Jersey*, at Newton, blue crystals in gran. limestone, with grass-green hornblende, mica, tourmaline, rare; at Vernon, near State line, red crystals, often several inches long. In *Pennsylvania*, in Delaware Co., in Aston, near Village Green, in large crystals; at Mineral Hill, in loose cryst.; in Chester Co., at Unionville, abundant in crystals, some masses weighing 4,000 lbs., and crystals occasionally 4 in. long, with tourmaline, margarite, and albite; in large crystals loose in the soil at Shimersville, Lehigh Co. In *Virginia*, in the mica schists of Bull Mt., Patrick Co.

Common at many points along a belt extending from Virginia across western North and South Carolina and Georgia to Dudleyville, Alabama; especially in Madison, Buncombe, Haywood, Jackson, Macon, Clay, and Gaston counties in North Carolina. The localities at which most work has been done are the Culsagee mine, Corundum hill, near Franklin, Macon Co., N.C., and 26 miles S. E. of this, at Laurel Creek, Ga. The corundum occurs in beds in chrysolite (and serpentine) and hornblendic gneiss, associated with a species of the chlorite group, also spinel, etc., and here as elsewhere with many minerals resulting from its alteration. (Cf. Shepard, Am. J. Sc., **4**, 109, 175, 1872; also Genth, l. c.) Fine pink crystals of corundum occur at Hiawassee, Towns Co., Georgia.

In *Colorado*, in small blue crystals in mica schist near Salida, Chaffee Co. Gem sapphires are found near Helena, Montana, in gold-washings and in bars in the Missouri river, especially the Eldorado bar. In *California*, in Los Angeles Co., in the drift of San Francisqueto Pass. In *Canada*, at Burgess, Ontario, red and blue crystals.

**Alt.**—Corundum undergoes extensive alteration, a series of aluminous minerals being the result. The commonest change is to the potash mica damourite, also to spinel, cyanite, fibrolite, zoisite, margarite, and other species. Cf. Genth, Am. Phil. Soc., **13**, 361, 1873; ibid., **20**, 381, 1882; Am. J. Sc., **39**, 47, 1890.

**Artif.**—Formed by decomposing potash alum by charcoal (Gaudin); in crystals by exposing to a high heat 4 pts. of borax and 1 of alumina (Ebelmen); by subjecting in a carbon vessel aluminium to the action of boric acid, the process yielding large rhombohedral plates (Deville & Caron); by addition to the last of chromium fluoride in varying amounts, affording the red sapphire or blue sapphire, or a fine green kind; by action of aluminium chloride on lime (Daubrée). Again by the fusion of alumina and minium in siliceous earthen crucibles, yielding a fusible lead aluminate which was subsequently decomposed by the silica, setting free the alumina in hexagonal crystals of considerable size (Frémy and Feil); under varying conditions rubies, sapphires, etc., being obtained. Also by the decomposition of aluminium chloride by magnesium and water vapor at a high temperature in a sealed tube (Meunier). Cf. Fouqué-Lévy, Synth. Min., 218–224, 1882; Bourgeois, Reprod. Min., 62, 1884.

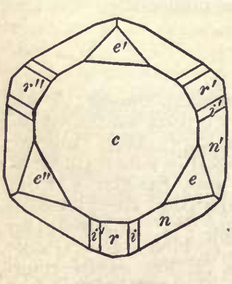
Twins: tw. pl. (1) *c*, penetration-twins; also comp. face often ⊥ *c* as in f. 5. (2) *r*, less common, usually as polysynthetic twinning lamellæ[5], producing a fine striation on *c*, and giving rise to a distinct parting or pseudo-cleavage ∥ *r*. Crystals often thick to thin tabular ∥ *c*, and grouped in parallel position or in rosettes; *c* faces striated ∥ edge *c*/*d* and other forms due to oscillatory combination; also in cube-like rhombohedrons; rhombohedral faces *u* horizontally striated and often rounded over in convex forms. Also columnar to granular, botryoidal, and stalactitic shapes; also lamellar, laminæ joined parallel to *c*, and variously bent, thick or thin; also granular, friable or compact.



Ural, Kk.

Parting: *c*, due to lamellar structure; also *r*, caused by twinning. Fracture subconchoidal to uneven. Brittle in compact forms; elastic in thin laminæ; soft and unctuous in some loosely adherent scaly varieties. H. = 5·5–6·5. G. = 4·9–5·3; of crystals mostly 5·20–5·25; of some compact varieties, as low as 4·2. Luster metallic and occasionally splendent; sometimes dull. Color dark steel-gray or iron-black; in very thin particles blood-red by transmitted light; when earthy, red. Streak cherry-red or reddish brown. Opaque, except when in very thin laminæ. Optically negative, artif. cryst., Michel. Sometimes feebly magnetic, and occasionally magnetipolar. Electrical conductivity $\parallel c$ nearly double that $\perp c$, the conductivity for both electricity and heat conforming to the crystalline symmetry, Bäckström[6].

Var. 1. *Specular.* Luster metallic, and crystals often splendent, whence the name *specular iron* (Glanzeisenerz *Germ.*). (*b*) When the structure is foliated or micaceous, the ore is called *micaceous* hematite (Eisenglimmer *Germ.*); some of the micaceous varieties are soft and unctuous (Eisenrahm *Germ.*).

2. *Compact columnar;* or fibrous. The masses often long radiating; luster submetallic to metallic; color brownish red to iron-black. Sometimes called *red hematite*, the name hematite among the older mineralogists including the fibrous, stalactitic, and other solid massive varieties of this species, also limonite and turgite. Often in reniform masses with smooth fracture, called *kidney ore* (rother Glaskopf, Blutstein, Eisenniere, *Germ.*).

3. *Red Ocherous. Reddle* or *Ruddle* (Röthel *Germ.*). Red and earthy. Often specimens of the preceding are red ocherous on some parts. *Reddle* and *red chalk* are red ocher, mixed with more or less clay.

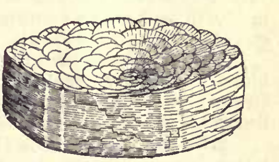
9.



1–4, Simple forms. 5, Vesuvius, Sbk. 6, Binnenthal, Calderon. 7, 8, Elba. 9, St. Gothard.

4. *Clay Iron-stone; Argillaceous hematite.* Hard, brownish black to reddish brown, often in part deep red; of submetallic to unmetallic luster; and affording, like all the preceding, a red streak. It consists of oxide of iron with clay or sand, and sometimes other impurities. (*b*) When reddish in color and jasper-like in texture, often called *jaspery* clay iron-stone. (*c*) When consisting of minute flattened concretions, it is the *lenticular iron ore;* also called *fossil ore.* Foerste has shown that this oölitic ore in the Clinton group consists largely of the fragmental remains of bryozoan corals. *Itabiryte* is a schist resembling mica-schist, but containing much specular ore in grains or scales, or in the micaceous form.

**Comp.**—Iron sesquioxide, $Fe_2O_3$ = Oxygen 30, iron 70 = 100. Sometimes contains titanium and magnesium, and passing into ilmenite, wh. see.

**Pyr., etc.**—B.B. infusible; on charcoal in R.F. becomes magnetic; with borax gives the iron reactions. With soda on charcoal in R.F. is reduced to a gray magnetic metallic powder. Soluble in concentrated hydrochloric acid.

**Obs.**—This ore occurs in rocks of all ages. The specular variety is mostly confined to crystalline or metamorphic rocks, but is also a result of igneous action about some volcanoes, as at Vesuvius. Many of the geological formations contain the argillaceous variety or clay iron-stone, which is mostly a marsh-formation, or a deposit over the bottom of shallow, stagnant water; but this kind of clay iron-stone (that giving a red powder) is less common than the corresponding variety of limonite. The beds that occur in metamorphic rocks are sometimes of very great thickness, and, like those of magnetite in the same situation, have resulted from the alteration of stratified beds of ore, originally of marsh origin, which were formed at the same time with the enclosing rocks, and underwent metamorphism, or a change to the crystalline condition, at the same time.

Beautiful crystallizations of this species are brought from the island of Elba, which has afforded it from a very remote period, and is described by Ovid as "Insula inexhaustis chalybdum generosa metallis." The surfaces of the crystals often present an irised tarnish and brilliant luster. St. Gothard affords beautiful specimens, composed of crystallized tables grouped in the form of rosettes (*Eisenrosen*), and accompanying crystals of adularia. Near Limoges, France, it occurs in large crystals. Fine crystals are the result of volcanic action at Etna and Vesuvius, and particularly in Fossa Cancharone, on Monte Somma, where it incrusts the ejected lavas; also formed in most recent eruptions about the fumaroles; in that of 1855, in fine crystallizations about the fumaroles, some so thin as to be blood-red by transmitted light (Scacchi). Arendal in Norway, Långban and Nordmark in Sweden, Framont in Lorraine, Dauphiné, Binnenthal and Tavetsch, Switzerland, also Cleator Moor in Cumberland, afford splendid specimens. Red hematite occurs in reniform masses of a fibrous concentric structure, near Ulverstone in Lancashire, in Saxony, Bohemia, and the Harz. In Westphalia it occurs as pseudomorphs after calcite. In Brazil it is associated with quartz. In Spain, also Chili, there are immense beds.

In *N. America*, widely distributed, and sometimes in beds of vast thickness in rocks of the Archæan age, as in the upper peninsula of Michigan, in the Marquette district, also in Menominee county and west of Lake Agogebic in Gogebic county; further through northern Wisconsin, Florence, Ashland and Dodge Cos., and in Minnesota near Vermilion lake, St. Louis Co.; in Missouri, at the Pilot Knob and the Iron Mtn.; the former 650 feet high, consisting mainly of an Archæan quartz rock, and having specular iron in the upper part, the iron ore in heavy beds interlaminated with quartz; the latter 200 feet high, and consisting at surface of massive hematite in loose blocks, many 10 to 20 tons in weight.

In New York, in Oneida, Herkimer, Madison, Wayne Cos., a lenticular argillaceous var. (*fossil ore*), constituting one or two beds in the Clinton group of the Upper Silurian; the same in Pennsylvania, and as far south as Alabama; and in Canada, and Wisconsin to the west; in Alabama, there are extensive beds along each border of the anticlinal valleys, through Jackson, Marshall, Blount, Cherokee, Etowah, Jefferson, Tuscaloosa counties (Min. Res. U. S., 1887); prominent mines are near Birmingham.

Besides these regions of enormous beds, there are numerous others of workable value, either crystallized or argillaceous. Some of these localities, interesting for their specimens, are in northern New York, at Gouverneur, Antwerp, Hermon, Edwards, Fowler, Canton, etc.; Woodstock and Aroostook, Me.; at Hawley, Mass., a micaceous variety; at Piermont, N. H., id.; in North and South Carolina a micaceous variety in schistose rocks, constituting the so-called *specular schist*, or *itabiryte*.

Named *hematite* from *αἷμα*, *blood*, it seeming, says Theophrastus, as if formed of concreted blood. This old Greek author speaks afterwards of a second kind of hematites (*'Αιματίτης ξανθή*), which was of a yellowish white color, probably a yellow ocher, an impure form of limonite, the species long called *brown hematite*.

**Alt.**—By deoxidation through organic matter forms *magnetite* or protoxides; and from the latter comes siderite by combination with carbonic acid; or by further deoxidation through sulphureted hydrogen forms *pyrite*. By combination with water forms limonite. Limonite, magnetite, and pyrite constitute occurring pseudomorphs after hematite.

**Artif.**—Formed in crystals by the action of steam on ferric chloride, regarded as the probable method of origin of the hematite of lavas; also by the action of ferric chloride on lime (Daubrée); by the action of a stream of hydrochloric acid gas on $Fe_2O_3$, the application being made very slowly, lest it be all converted to chloride. etc.

On the formation of hematite by sublimation, see Arzruni, Zs. Kr., **18**, 44, 1890, who also gives literature.

**Ref.**—[1] Vesuvius, Min. Russl., **1**, 3, 1853; Mohs gives 94° 2′; Lévy, Mlr., 93° 50′. [2] Cf. Mlr., Min., 236, 1852; also earlier, Hbg., Min. Not., **5**, 43, 1863, **6**, et seq., 1864 (list of planes on p. 6), **8**, 33, 41, **9**, 52, 1870; Rath, Pogg., **128**, 420, 1866; Svr., Att. Acc. Torino, **7**, 377, 1872; Scc., Contr. Min., II, 1 (Att. Acc. Napoli, **6**, 1873). Also Bkg., Zs. Kr., **1**, 562, 1877, **2**, 416, 1878.

[3] Flink, Pajsberg, also the following rhombohedrons not all above doubt: $1\cdot0\cdot\bar{1}\cdot10$, $2\cdot0\cdot\bar{2}\cdot15$, $10\bar{1}7$, $10\bar{1}6$, $10\bar{1}5$, $0\cdot1\cdot\bar{1}\cdot11$, $01\bar{1}7$, $01\bar{1}6$, Ak. H. Stockh., Bihang, **13** (2), 7, 25, 1888. [4] Id., Nordmark, ibid., p. 32.

[5] Bauer, Zs. G. Ges., **26**, 186, 1874; Mgg., Jb. Min., **1**, 216, 1884, **2**, 35, 1886. This seems to have been observed by Mohs as noted by Strüver, Rend. Accad. Linc., **4**, 347, 1888. [6] Bäckström, Öfv. Ak. Stockh., **45**, 533, 1888; also thermo-electric behavior, ibid., p. 553.

MARTITE. Martit *Breith.*, Char., 233, 1832. Martite is iron sesquioxide under an isometric form, occurring in octahedrons or dodecahedrons like magnetite, and believed to be pseudomorphous after magnetite; perhaps in part also after pyrite. Parting octahedral like magnetite. Fracture conchoidal. H. = 6–7. G. = 4·809–4·832, Brazil, Breith.; 4·65, Puy-de Dôme; 4·35, Frassem, Dewalque; 5·15, Brazil, Rg.; 5·194–5·205, Brazil, Lcx.; 5·33, Monroe, N. Y., Hunt. Luster submetallic. Color iron-black, sometimes with a bronzed tarnish. Streak reddish brown or purplish brown. Not magnetic, or only feebly so. The crystals are sometimes embedded in the massive sesquioxide. They are distinguished from magnetite by the red streak, and very feeble, if any, action on the magnetic needle.

Found at the localities mentioned; also in Vermont at Chittenden; in the Marquette iron region south of Lake Superior, where crystals are common in the ore, as if all of it, or the greater part, were martite; Bass lake, Ontario; at Monroe, N. Y.; in a rock containing quartz, feldspar, and hornblende, and embedded in each of these minerals in Digby county, Nova Scotia; at the Cerro de Mercado, Durango, Mexico, in large octahedrons (Silliman, Am. J. Sc., **24**, 375, 1882); in the schists of Minas Geraes, Brazil; at the Rother Adler mine near Rittersgrün, Saxony; in Moravia, near Schönberg, in granite.

The martite of Monroe contains some FeO, Brush. The octahedral crystals from Chittenden, Vt., according to D. Olmstead, are part true magnetite, with a black powder; part give a slightly reddish streak, with little FeO; and part give a red powder and contain no FeO.

Whether the crystals of martite are original crystals or pseudomorphs after either magnetite or pyrite, or both, is still questioned (cf. Lcx., Bull. Soc. Min., **12**, 49, 1889); but the latter seems to be much the most probable view. Rammelsberg found 1·83–2·30 p. c. FeO in the Brazil crystals. The octahedrons from the fumaroles of Vesuvius afforded him (Min. Ch., 159, 1860) $Fe_2O_3$ 92·91, FeO 6·17, MgO 0·82 = 99·90; G. = 5·235. The crystals from Frassem, France, contain 0·2 p. c. of sulphur, which suggests that these may be pseudomorphs after pyrite. The Brazilian crystals are pure $Fe_2O_3$, as found by Lacroix.

RAPHISIDERITE. Rafisiderite *A. Scacchi*, Att. Accad. Napoli, Mem., **3**, read Dec. 1, 1888. A form of iron sesquioxide occurring in the tufa of Pianura and Fiano in the Campania; it appears in minute acicular crystals for which an orthorhombic form is suggested.

**233. ILMENITE** or MENACCANITE. Specular Iron pt., Eisensand pt., of last cent. Menachanite (fr. Cornwall) *Wm. McGregor*, J. de Phys., 72, 152, 1791, Crell's Ann., 1791, and Kirwan's Min., 1796 (making it to consist of iron and an oxide of a probably new metal). Eisenhaltige Titanerz, Menakanit (from Cornwall) *Klapr.*, Beitr., **2**, 226; (fr. Aschaffenberg) ib., 232, 235, 1797. Titane oxydé ferrifère *H.*, Tr., 1801. Mänaken *Karst.*, Tab., 74, 1808. Titaneisenstein, Titaneisen, *Germ.* Titanic or Titaniferous Iron. Crichtonite (spelled Craitonite) *Bourn.*, Cat., 430, 1813. Axotomes Eisenerz (fr. $\pi\pi_, = 39° 39'$
$nn_, = 52° 10'$

Twins: (1) tw. pl. *c*; (2) *r*, as tw. lamellæ, less common than with hematite. Crystals usually thick tabular; also acute rhombohedral. Often in thin plates or laminæ. Massive, compact; in embedded grains, also loose as sand.

Fracture conchoidal. H. = 5–6. G. = 4·5–5. Luster submetallic. Color iron-black. Streak submetallic, powder black to brownish red. Opaque. Influences slightly the magnetic needle.

**Comp., Var.**—If normal, $FeTiO_3$ = Oxygen 31·6, titanium 31·6, iron 36·8 = 100, or Titanium dioxide 52·7, iron protoxide 47·3 = 100; or $(Fe,Ti)_2O_3$ since $Fe_2O_3$ and $Ti_2O_3$ are isomorphous. The ratio of titanium to iron varies widely, usually corresponding (Rg.) to $m FeTiO_3 . n Fe_2O_3$. Sometimes also contains magnesium, replacing the ferrous iron.

The varieties recognized arise mainly from the proportions of iron to titanium. They have been named as follows, commencing with that containing the most titanium. No satisfactory external distinctions have yet been made out, and their true relations are in many cases in doubt.

1. *Kibdelophane.* About 30 p. c. titanium. In crystals, but usually massive, or in thin plates; *rr'* = 94° 1'; G. = 4·661, Gastein, Mohs; 4·723–4·735, ib., Breith.

2. *Crichtonite.* Composition essentially like that of the preceding. In acute rhombohedrons, with basal cleavage; G. = 4·79, from St. Cristophe (original); 4·689, same compound from Ingelsberg, Rg.; luster bright.

3. *Ilmenite.* Contains 26–30 p. c. titanium, and near the preceding in composition, but with more sesquioxide of iron (anal. 9). Crystallized and massive; G. = 4·895, from Ilmen Mts. (original), Breith.; 4·81–4·873, ib., Rg. For same compound fr. Egersund, 4·744–4·791, Rg.; fr. Kragerö 4·701.

4. *Menaccanite.* About 25 p. c. of titanium, and with more iron sesquioxide than in the preceding. Massive, and in grains or as a sand (Eisensand). G. = 4·7–4·8, fr. near Menaccan, Cornwall (orig.). Similar compound from Iserwiese, 4·676–4·752, Rg.

5. *Hystatite.* 15–20 p. c. titanium, and much $Fe_2O_3$. $rr'$ = 93° 50'; G. = 5, Arendal (orig.). *Washingtonite* belongs here. Occurs in large tabular rather dull crystals; $rr'$ = 94° approximately; G. = 4·963, Westerly, R. I., and 5·016, Litchfield, Ct. (orig.), Shepard; for latter, 4·986, Rg.

6. *Uddevallite* D. About 10 p. c. titanium and 70 p. c. of $Fe_2O_3$. The Aschaffenberg titanic iron is near this. It occurs massive and in plates, and has G. = 4·78.

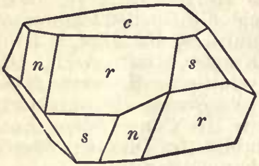
7. *Basanomelan* (*Eisenrosen* of the Alps). 6 to 8 p. c. Ti, and 75 to 83 of $Fe_2O_3$; G. = 4·95–5·21. It is properly a titaniferous hematite. See hematite.

8. *Kragerö hematite.* Containing less than 3 p. c. of titanium.

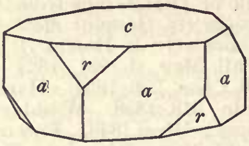
9. *Magnesian Menaccanite; Picrotitanite* D. Contains 10 to 15 p. c. of magnesia; formula $(Fe,Mg)TiO_3$; G. = 4·293–4·313. Named from *πίκρος, bitter,* in allusion to the magnesia.

The *Mohsite* is of uncertain locality and composition. Crystals tabular; in twins; no cleavage observable.

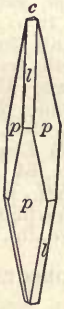
1.



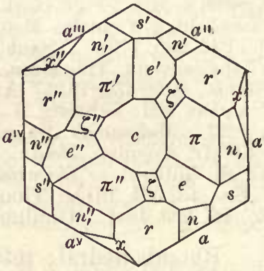
2.



3.



4.



1, Ilmen Mts., Kk. 2, Washingtonite. 3, Crichtonite, Dx. 4, Ilmen Mts., Kk.

The loose *Iron-sand* of Iserwiese, called *iserine,* is in part, at least, in isometric octahedrons; and the *trappisches Eisenerz,* Breith., is similar. See iserine beyond.

*Paracolumbite* or *Parailmenite* of Shepard is an iron-black mineral from 1 m. S. W. of Taunton, Mass., having H. about 5. Pisani has proved it to be this species. He found G. = 4·353, H. 4·5.

On the composition of titanic iron, see Rg., Pogg., **104**, 497, 1858, Min. Ch., 148, 1875 Friedel and Guérin, Ann. Ch. Phys., **8**, 38, 1876, who describe artif. cryst. of $Ti_2O_3$ with $cr = 56° 40'$, also isomorphous mixtures of $Ti_2O_3$ and $Fe_2O_3$

**Pyr., etc.**—B.B. infusible in O.F., although slighly rounded on the edges in R.F. With borax and salt of phosphorus reacts for iron in O.F., and with the latter flux assumes a more or less intense brownish red color in R.F.; this treated with tin on charcoal changes to a violet-red color when the amount of titanium is not too small. The pulverized mineral, heated with hydrochloric acid, is slowly dissolved to a yellow solution, which, filtered from the undecomposed mineral and boiled with the addition of tin-foil, assumes a beautiful blue or violet color. Decomposed by fusion with bisulphate of sodium or potassium.

**Obs.**—Occurs in beds in gneiss and other crystalline rocks; also in small particles in many crystalline rocks, often associated with magnetite. The principal European localities of this species have been enumerated above in connection with the statement of varieties. One of the most remarkable is at Kragerö, Norway, where it occurs in veins or beds in diorite, which sometimes afford crystals weighing over 16 pounds. Others are Egersund, Arendal, Snarum in Norway; Miask in the Ilmen Mts.; Bourg d'Oisans, Dauphiné; St. Gothard, etc.

Fine crystals, sometimes an inch in diameter, occur in Warwick, Amity, and Monroe, Orange Co., N. Y., embedded in serpentime and white limestone, and associated with spinel, chondrodite, rutile, etc.; also 4 m. west of Edenville, and near Greenwood furnace with spinel and chondrodite; also at Chester and South Royalston, Mass.; Litchfield, Conn. (*washingtonite*); Troy, Vt., with chlorite. Vast deposits or beds of titanic ore occur at Bay St. Paul in Quebec, Canada, in syenite; one bed, 90 feet thick, continues on in view for 300 feet, and probably far beyond; also in the Seignory of St. Francis, Beauce, mixed with magnetite as a bed 45 feet thick in serpentine; G. = 4·56–4·66; also with labradorite at Château Richer. Grains are found in the gold sand of California.

ISERINE. Titaneisenstein pt., Magnetischer Eisen-Sand pt., *Wern.* Iserin (fr. Iser) *Wern.*, Letztes Min., 26, 52, 1817, Hoffm. Min., **4**, 258, 1817. Oktaëdrisches Titaneisen-Oxyd *Wern.* Iserin *Breith.*, Char., 51, 1820. Hexaedrisches Eisen-Erz *Mohs*, 436, 1839. Iserite. Supposed to be isometric titanic iron, and, like martite, to be pseudomorphous. Anals. 13–16, above. The locality of Iserwiese gave the name to this mineral. The titanic iron-sand is partly in octahedral forms, and this portion, if not all, is the *iserine*. Yet it is still doubted whether the octahedrons are regular octahedrons, or whether they are acute rhombohedrons with truncated apices, and therefore true ilmenite. Similar sands come from many other localities, as from Bohemia, Saxony, Calabria, Puy-de-Dôme in France.

**Alt.**—The titanic iron of massive rocks is extensively altered to a dull white opaque substance, called leucoxene by Gümbel (Die paläolith. Eruptivgesteine d. Fichtegebirges, 22, 1874). This for the most part is to be identified with titanite. Cf. Cathrein, Zs. Kr., **6**, 244, 1881, also Rosenb., Mikr. Phys. Min., 332, 1885.

**Ref.**—[1] Min. Russl., **6**, 350, 1874. [2] Cf. Kk., ib., **1**, 16 and l. c., also Mlr., Min., p. 239, 1852. A crystal from the Binnenthal, regarded as tetartohedral and distinct from the associated hematite, gave Bkg., $T\,(\bar{1}2\bar{1}5, \frac{2}{5}\text{-}2\,1), q\,(\bar{1}2\bar{1}6, \frac{1}{3}\text{-}2\,1)$, Zs. Kr., **1**, 576, 1877. Cf. also Sbk., Jb. Min., 287, 1878. Planes on crystals from Cavradi, and on the Swiss "Eisenrosen," are referred to hematite. Bücking includes in his list of planes a large number of forms given by Strüver for *corundum!*

HYDROILMENITE *C. W. Blomstrand*, Minnesskrift Fys. Sällsk., Lund, No. 3, p. 4, 1878.

A partially altered variety of ilmenite. It forms thin curved plates with tolerably distinct rhombohedral cleavage [pseudo-cleavage]; $rr' = 93°–94°$. G. = 4·066–4·136. Color iron-black. Streak dark gray. Luster metallic. Not magnetic. Analysis:

| $TiO_2$ | $SiO_2$ | $Fe_2O_3$ | FeO | MnO | CaO | MgO | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|
| 54·23 | 1·40 | 14·99 | 21·91 | 6·34 | 0·45 | 0·19 | 1·33 | = 100·84 |

The mineral decomposes readily, and finally becomes coated with a yellowish white crust consisting essentially of $TiO_2$. Probably altered from normal ilmenite by the assumption of water. From Småland, Sweden.

FERROZINCITE *Adam*, Tabl. Min., 78, 1869. A hydrous mineral containing $Fe_2O_3$ and ZnO.

## III. Intermediate Oxides.

The species here included are retained among the oxides, although chemically considered they are properly oxygen-salts, aluminates, ferrates, manganates, etc., and hence in a strict classification to be placed in section 5 of the Oxygen-salts.

2. CEYLONITE. Ceylanite *Delameth.*, J. de Phys., **42**, 23, 1793. Zeylanit *Karst.*, Tab., 28, 72, 1800. Zeilanite Pleonaste *H.*, Tr., 1801. Ceylonit *Rg.* Candite (fr. Candy, Ceylon) *Bourn.*

3. CHLOROSPINEL *G. Rose*, Pogg., **50**, 652, 1840. Gahnit *B. de Marni*, 1833.

4. PICOTITE *Charpentier*, J. Mines, 32, 321, 1812; Gilb. Ann., **47**, 205, 1814. Chrom-ceylonite.

Isometric. Observed forms[1]:

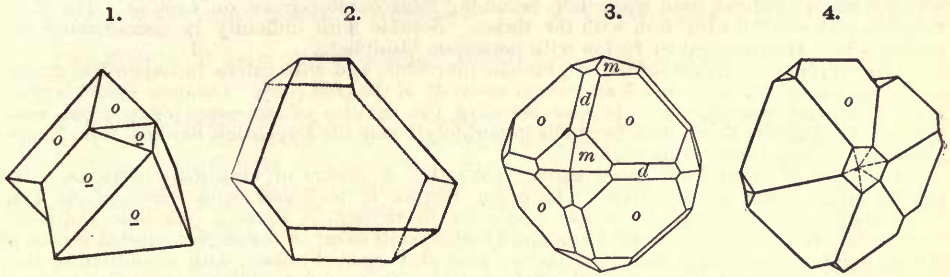
*a* (100, *i-i*)[2] rare
*d* (110, *i*)
*o* (111, 1)
*f* (310, *i*-3)[3]
*π* (776, $\frac{7}{6}$)[6]
*r* (332, $\frac{3}{2}$)
*p* (221, 2)
*q* (331, 3)[2]
*ξ* (771, 7)[3]
*φ* (611, 6-6)[3]
*m* (311, 3-3)
*n* (211, 2-2)[3]
*β* (322, $\frac{3}{2}$-$\frac{3}{2}$)[4]
*x* (531, 5-$\frac{5}{3}$)[3]

Twins: tw.-pl. and comp.-face *o* common (f. 1), hence often called *spinel-twins;* also repeated (f. 4) and polysynthetic[5], producing tw. lamellæ with striations on *o*. Habit octahedral; *o* faces sometimes convex; habit rarely cubic.

Cleavage: *o* imperfect. Fracture conchoidal. Brittle. H. = 8. G. = 3·5–4·1. Luster vitreous; splendent to nearly dull. Color red of various shades, passing into blue, green, yellow, brown and black; occasionally almost white. Streak white. Transparent to nearly opaque. Refractive indices:

$$n_r = 1{\cdot}7121 \text{ Li} \qquad n_y = 1{\cdot}7155 \text{ Na} \qquad n_{bl} = 1{\cdot}7261 \text{ Dx.}^7$$

Phosphorescent with a red light, yielding a crimson line ($\lambda = 6857$ Crookes) in the spectroscope. Etching-figures as with magnetite[8].



1, Spinel twin. 2, Crystal flattened ‖ *o*. 3, Amity, N. Y. 4, Strüver[5].

**Comp., Var.**—Magnesium aluminate, $MgAl_2O_4$ or $MgO.Al_2O_3$ = Alumina 71·8, magnesia 28·2 = 100. The magnesium may be in part replaced by ferrous iron or manganese, and the aluminium by ferric iron and chromium.

**Var.**—1. RUBY SPINEL or *Magnesia Spinel.*—Clear red or reddish; transparent to translucent; sometimes subtranslucent. G = 3·52–3·58; 3·63–3·71 Church. Composition normal, with little or no iron, and sometimes chromium oxide to which the red color has been ascribed. The varieties are: (*a*) *Spinel-Ruby*, deep red; (*b*) *Balas-Ruby*, rose-red; (*c*) *Rubicelle*, yellow or orange-red; (*d*) *Almandine*, violet.

2. CEYLONITE or *Pleonaste, Iron-Magnesia Spinel.*—Color dark green, brown to black, mostly opaque or nearly so; G. = 3·5–3·6. Contains iron replacing the magnesium and perhaps also the aluminium, hence the formula $(Mg,Fe)O\ Al_2O_3$ or $(Mg,Fe)O.(Al,Fe)_2O_3$.

3. CHLOROSPINEL or *Magnesia-Iron Spinel.*—Color grass-green, owing to the presence of copper; G. = 3·591–3·594. Contains iron replacing the aluminium, $MgO.(Al,Fe)_2O_3$.

4. PICOTITE or *Chrome-Spinel.*—Contains chromium and also has the magnesium largely replaced by iron, $(Mg,Fe)O.(Al,Cr)_2O_3$, hence lying between spinel proper and chromite. G. = 4·08. Color dark yellowish brown or greenish brown. Translucent to nearly opaque. The original occurs in disseminated grains, rarely octahedral crystals, in a rock occurring about L. Lherz, called *Lherzolite* by Delametherie (T. T., 2, 281, 1797), and earlier described by Picot de la Peyrouse (Mem. Ac. Toulouse, 3, 410), after whom *picotite* is named.

The analyses of Thomson (Min., 1, 214, 1836), showing considerable lime, *e. g.* 10·6 p. c., in a spinel from Amity, N. Y., are probably erroneous.

A red octahedral mineral from Dornbach is a titaniferous variety (5·68 p. c. $TiO_2$) rich in iron, according to Kosmann. Ber. nied. Ges., p. 144, July 19, 1869.

**Anal.**—1, 2, Abich, Pogg., **23**. 305, 1831, also De Spinello, Inaug. Diss. (in Latin), Berlin, 1831. 3, Vogel, Rg. Min. Ch., 136, 1875. 4, Reuter, ibid. 5, A. M. Thomson, Liversidge, Min. N. S. **Pyr., etc.**—B.B. alone infusible; red variety changes to brown, and even black and opaque, as the temperature increases, and on cooling becomes first green, and then nearly colorless, and at last resumes the red color. Slowly soluble in borax, more readily in salt of phosphorus, with which it gives a reddish bead while hot, becoming faint chrome-green on cooling. The black varieties give reactions for iron with the fluxes. Soluble with difficulty in concentrated sulphuric acid. Decomposed by fusion with potassium bisulphate.

**Obs.**—Spinel occurs embedded in granular limestone, and with calcite in serpentine, gneiss, and allied rocks. Ruby spinel is a common associate of the true ruby. Common spinel is often associated with chondrodite. It also occupies the cavities of masses ejected from some volcanoes. Picotite is common in grains in peridotyte and the serpentine derived from it, also enclosed in chrysolite in other rocks.

In Ceylon, in Siam, and other eastern countries, it occurs of beautiful colors, as rolled pebbles in the channels of rivers. In upper Burma it is found with ruby (cf. p. 212). Pleonaste is found at Candy, in Ceylon. At Åker, in Sweden, is found a pale blue and pearl-gray variety in limestone. Small black splendent crystals occur in the ancient ejected masses of Monte Somma, with mica and vesuvianite; also at Pargas, Finland, with chondrodite, etc.; in compact gehlenite at Monzoni, in the Fassa valley. In granular limestone (cipolin) enclosed in gneiss at Mercus and Arignac north of Tarascon, on the borders of l'Ariège, where the association with brucite, chondrodite, scapolite, pyroxene, etc., is very similar to that at Warwick, New York, and at Pargas (Lcx., Bull. Soc. Min., **12**, 518, 1889). In the gold sands of New South Wales at various points.

From Amity, N. Y., to Andover, N. J., a distance of about 30 miles, is a region of granular limestone and serpentine, in which localities of spinel abound; colors, green, black, brown, and less commonly red, along with chondrodite and other minerals. A mile S.W. of Amity, on J. Layton's farm, is a remarkable locality; also on W. Raynor's farm, a mile N.; another half mile N. affording grayish red octahedrons; and others to the south. Localities are numerous about Warwick, and also at Monroe and Cornwall, though less favorable for exploration than those at Amity. Franklin, N. J., affords crystals of various shades of black, blue, green, and red, which are sometimes transparent, and a bluish green ceylonite variety here has the luster of polished steel; Newton, N. J., pearl-gray crystals, with blue corundum, tourmaline, and rutile; at Byram, red, brown, green, and black colors, with chondrodite; Sterling, Sparta, Hamburgh, and Vernon, N. J., are other localities. Light blue spinels occur sparingly in limestone in Antwerp, Jefferson Co., N. Y., 2½ m. S. of Oxbow, and rose and reddish brown in Gouverneur. 2 m. N. and ¾ m. W. of Somerville, St. Lawrence Co.; green, blue, and occasionally red varieties occur in granular limestone at Bolton, Boxborough, Chelmsford, and Littleton, Mass. Octahedral crystals tessellated like chiastolite occur embedded in slate near Springfield, Mass. Soft octahedral crystals occur in Warwick, which are pseudomorphs, consisting partly of steatite or serpentine. With the corundum of North Carolina, as at the Culsagee mine, near Franklin, Macon Co.; similarly at Dudleyville, Alabama. Spinel ruby at Gold Bluff, Humboldt Co., Cal.

Good black spinel is found in Burgess, Ontario; a bluish spinel having a rough cubic form occurs at Wakefield, Ottawa Co.; blue with clintonite at Daillebout, Joliette Co., Quebec.

**Alt.**—Observed altered to steatite, serpentine, hydrotalcite, mica.

**Artif.**—Formed in crystals by heating a mixture of alumina and magnesia with boracic acid, and also, for red spinel, some oxide of chrome; for black, oxide of iron (Ebelmen); by using fluorides of aluminium and magnesium and boracic acid, with heat (Deville & Caron); by action of aluminium chloride in vapor on magnesia (Daubrée). See also Meunier, who uses cryolite and aluminium chloride, Bull. Soc. Min., **10**, 191, 1887; and, in general, Fouqué-Lévy, Synth. Min., 227–232, 1882; Bourgeois, Reprod. Min., 69–76, 1884.

**Ref.**—[1] Mlr., Min., p. 263, 1852. [2] Hbg., Min. Not., **8**, 45, 1868. [3] Svr., pleonaste from the Albani Mts., Zs. Kr., **1**, 233, 1877. [4] Erem., Turkestan, ibid., **4**, 642. [5] Svr., Zs. Kr., **2**, 480, 1878. [6] Cathrein, Monzoni, Min. Mitth., **10**, 398, 1888. [7] Dx., N. R., **204**, 1867. [8] Becke, Min. Mitth., **7**, 224, 1885.

An unknown mineral, occurring in colorless octahedrons and supposed to belong to the spinels, has been noted in the phonolyte of Olbrück; see Bull. Soc. Min., **9**, 85, 1886, also Jb. Min., **2**, 180, 1886.

**235. HERCYNITE.** Hercynit *F. X. Zippe*, Min. Böhm., 1839. Hercinite *bad orthogr.* Iron Spinel.

Isometric. Occurs massive, fine granular.

H. = 7·5–8. G. = 3·91–3·95. Luster vitreous, externally dull. Color black. Streak dark grayish green to leek-green. Opaque.

**Comp.**—Iron aluminate, $FeAl_2O_4$ = Alumina 58·6, iron protoxide 41·4 = 100.

**Anal.**—B. Quadrat, Lieb. Ann., **55**, 357, 1845.

$Al_2O_3$ 61·17 MgO 2·92 FeO 35·67 = 99·76

**Pyr., etc.**—B.B. infusible. The heated powder becomes brick-red, and gives iron reactions. With soda fuses only imperfectly to an olive-green mass.

**Obs.**—From Ronsberg, at the eastern foot of the Böhmerwald, with corundum, iron hydroxide; also scattered through the granulytes of Saxony, Kalkowsky, Zs. G. Ges., **33**, 533, 1871. A related iron-alumina spinel, with about 9 p. c. MgO, occurs with magnetite and corundum in Cortlandt township, Westchester Co., N. Y. (Williams, Am. J. Sc., **33**, 194, 1887).

Named from the Latin of the Bohemian Forest, *Silva Hercynia* (Plin., **4**, 25, 28).

**236. GAHNITE.** Zinc-Spinel. Automolite (fr. Falun) *Ekeberg*, Afh., **1**, 84, 1806. Gahnit *v. Moll*, Efem., **3**, 78, 1807. Spinelle Zincifère *H.*, Tabl., 67, 99, 1809. Dysluite (fr. Sterling, N. J.) *Keating*, J. Ac. N. Sci., Philad., **2**, 287, 1821; *Shep.*, Min., **1**, 158, 1832, **2**, 176, 1835; *Thomson*, Min., **1**, 220, 1836. Kreittonite *Kbl.*, J. pr. Ch., **44**, 99, 1848. Spinellus superius *Breith.*, Handb., 623, 1847.

Isometric. Observed forms:

*a* (100, *i-i*) *d* (110, *i*) *o* (111, 1) *m* (311, 3-3)

Twins: tw.-pl. *o*. Habit octahedral, often with planes striated ‖ edge *d/o*; also less commonly in dodecahedrons and modified cubes.

Cleavage: *o* indistinct. Fracture conchoidal to uneven. Brittle. H. = 7·5–8. G. = 4·0–4·6. Luster vitreous, or somewhat greasy. Color dark green, grayish green, deep leek-green, greenish black, bluish black, yellowish, or grayish brown; streak grayish. Subtransparent to nearly opaque.

**Comp., Var.**—Zinc aluminate, $ZnAl_2O_4$ = Alumina 55·7, zinc oxide 44·3 = 100. The zinc is sometimes replaced by manganese or ferrous iron, the aluminium by ferric iron.

**Var.**—1. AUTOMOLITE, or *Zinc Gahnite.*—$ZnAl_2O_4$, with sometimes a little iron. G. = 4·1–4·6. Colors as above given.

2. DYSLUITE, or *Zinc-Manganese-Iron Gahnite.*—$(Zn,Fe,Mn)O.(Al,Fe)_2O_3$. Color yellowish brown or grayish brown. G. = 4–4·6. Form the octahedron, or the same with truncated edges.

3. KREITTONNITE, or *Zinc-Iron Gahnite.*—$(Zn,Fe,Mg)O.(Al,Fe)_2O_3$. Occurs in crystals, and granular massive. H. = 7–8. G. = 4·48–4·89. Color velvet-black to greenish black; powder grayish green. Opaque.

**Pyr., etc.**—Gives a coating of zinc oxide when treated with a mixture of borax and soda on charcoal; otherwise like spinel.

**Obs.**—Occurs in talcose schist at Falun, Sweden (*automolite*); at Tiriolo, Calabria; at Bodenmais, Bavaria (*kreittonite*); Minas Geraes, Brazil.

In the U. S., at Franklin Furnace, N. J., with franklinite and willemite; also at Sterling Hill, N. J. (*dysluite*); with pyrite at Rowe, Mass.; at a feldspar quarry in Delaware Co., Penn.; sparingly at the Deake mica mine, Mitchell Co., N. C.; at the Canton Mine, Georgia; with galena, chalcopyrite, pyrite at the Cotopaxi mine, Chaffee Co., Col., in part altered to a chloritic mineral (cf. Genth, l. c.).

Named after the Swedish chemist Gahn. The name *Automolite*, of Ekeberg, is from *αὐτόμολος*, *a deserter*, alluding to the fact of the zinc occurring in an unexpected place. Von Moll objected to such an idea in nature, and named the species the next year after J. G. Gahn, the discoverer (1745–1818). His name is here applied to the whole group of zinc spinels, and automolite retained for the special variety so named.

**Artif.**—Observed with tridymite in a zinc furnace from the alteration of the distillation vessels, Jb. Min., **1**, 120, 1881; also in a fayalite slag at the Freiberg furnaces, ibid., **1**, 170, 1882.

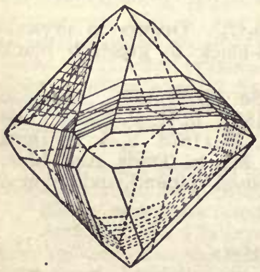
Twins: tw.-pl. *o*, sometimes as polysynthetic twinning lamellæ[9], producing striations on an octahedral face and often a pseudo-cleavage (f. 1). Most commonly in octahedrons, also in dodecahedrons with faces striated ‖ edge *d*/*o* from oscillatory combination (f. 2); in dendrites between plates of mica; crystals sometimes highly modified; cubic forms rare. Massive with laminated structure; granular, coarse or fine; impalpable.

1.



Port Henry, Kemp.

Cleavage not distinct; parting octahedral, often highly developed[9]. Fracture subconchoidal to uneven. Brittle. H. = 5·5–6·5. G. = 5·168–5·180 crystals. Luster metallic and splendent to submetallic and rather dull. Color iron-black. Streak black. Opaque, but in thin dendrites in mica nearly transparent and pale brown to black. Strongly magnetic, sometimes possessing polarity.

Etching-figures developed by acids on an octahedral face are inverted triangular pits, often with truncated edges; on a cubic face, quadrilateral elevations formed by dodecahedral planes or planes nearly coinciding with them; the chief etching-zone, in which the planes forming the figures lie (e.g., 443, 223, 337, etc.), is that of the trigonal trisoctahedrons; a secondary zone is that of the tetragonal trisoctahedrons.

**Comp., Var.**—$\overset{II}{Fe}\overset{III}{Fe}_2O_4$ or $FeO.Fe_2O_3$ = Iron sesquioxide 69·0, iron protoxide 31·0 = 100; or, Oxygen 27·6, iron 72·4 = 100. The ferrous iron sometimes replaced by magnesium, and rarely nickel; also sometimes titaniferous.

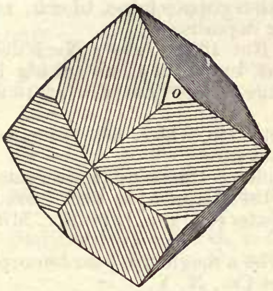
**Var.**—1. *Ordinary.* (*a*) In crystals. (*b*) Massive, with pseudo-cleavage, also granular, coarse or fine. (*c*) As loose sand. The property of polarity which distinguishes the *lodestone* (less properly written loadstone) is exceptional

The Scalotta crystals gave Cathrein: $Fe_2O_3$ 68·51, $Al_2O_3$ 1·10, $Cr_2O_3$ 0·55, FeO 27·70, MnO 0·42, MgO 2·09 = 100·37, Zs. Kr., 12, 37, 1886.

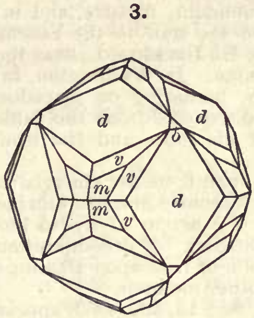
2. *Magnesian.* Talk-eisenerz, *Breith.* Schw. J., 68, 287, 1833.—$(Fe,Mg)O.Fe_2O_3$. G. = 4·41–4·42; luster submetallic; weak magnetic; in crystals from Sparta, N. J. An ore from the Mourne Mts., Ireland, contains 6·45 p.c MgO (Andrews), and an octahedron from Eisenach gave 1·20 p.c. MgO (Rg.). A New Zealand magnetite with G. = 4·67 has 7·15 MgO and 4·63 $Mn_3O_4$ (Chester, Min. Mag., 8, 125, 1889).

3. *Niccoliferous.* Petersen obtained in a magnetite from Pregratten in the Tyrolese Alps: $Fe_2O_3$ 68·92, FeO 29·32, NiO 1·76, $Mn_2O_3,Cr_2O_3,TiO_2$ *tr.* = 100. It occurred in a schistose serpentine in dodecahedral crystals; G. = 5·167. Jb. Min., 836, 1867.

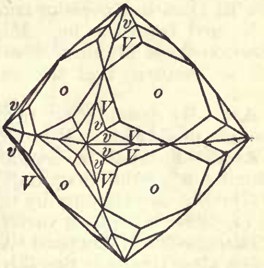
2.



3.



4.



2, Nordmark. Flink. 3. Scalotta, Cathrein. 4, Oberhollersbachthal, Pinzgau, Brugnatelli.

4. *Titaniferous.* Knop found 24·95 p. c. $TiO_2$ in octahedrons from Meiches, Vogelsberg, Lieb. Ann., 123, 348, 1862; also 4·08 $TiO_2$ with 6·85 $Al_2O_3$, 4·57 MgO in a magnetite from Oberbergen, Kaiserstuhl. Nordström gives 6·01 $TiO_2$, Kristianstad, G. För. Förh., 1, 14, 1872; Koenig gives 3·25 $TiO_2$ for a variety from Magnet Cove, Ark., Proc. Ac. Philad., 293, 1877. It is to be noted, however, that rutile, titanite, etc., have been observed in microscopic form intimately associated with magnetite. Cf. Cathrein, Zs. Kr., 8, 321, 1883.

5. *Manganesian, Manganmagnetite.* A variety from Vester Silfberg, Sweden, gave Weibull 3·80 p. c. MnO; another gave 6·27 p. c. G. = 5·064. Min. Mitth., 7, 109, 1886. See also jacobsite. Cf. also results of Chester quoted under 2.

6. *Ocherous.* Eisenmulm *Germ.* A black, earthy variety as that from Siegen. Eisenmohr is in magnetic scales, regarded as pseudomorph after micaceous hematite, as at Johanngeorgenstadt.

A variety containing vanadium and chromium in minute amounts is mentioned by Claassen.

**Pyr., etc.**—B.B. very difficultly fusible. In O.F. loses its influence on the magnet. With the fluxes reacts like hematite. Soluble in hydrochloric acid.

**Obs.**—Magnetite is mostly confined to crystalline rocks, and is most abundant in metamorphic rocks, though found also in grains in eruptive rocks. In the Archæan rocks the beds are of immense extent, and occur under the same conditions as those of hematite. It is an ingredient in most of the massive variety of corundum called emery. The earthy magnetite is found in bogs like bog-iron ore. Occurs in meteorites, and forms the crust of meteoric irons.

Present in dendrite-like forms in the mica of many localities following the direction of the lines of the percussion-figure, and perhaps of secondary origin. A common alteration-product of minerals containing iron protoxide, e.g., present in veins in the serpentine resulting from altered chrysolite.

The beds of ore at Arendal, Norway, and nearly all the celebrated iron mines of Sweden, consist of massive magnetite: Dannemora and the Täberg in Småland are entirely formed of it. Still larger mountains of it exist at Kurunavara and Gelivara, in Lapland. Falun, in Sweden, and Corsica, afford octahedral crystals, embedded in chlorite slate. Splendid dodecahedral crystals occur at Nordmark in Wermland. The most powerful native magnets are found in Siberia, and in the Harz; they are also obtained on the island of Elba. Other localities for the crystallized mineral are Traversella in Piedmont; Achmatovsk in the Ural; Scalotta near Predazzo in Tyrol, also Rothenkopf and Wildkreuzjoch; the Binnenthal; a cubic variety occurs in serpentine near Kraubat in Styria.

In N. America, it constitutes vast beds (some scores of feet thick) in the Archæan, in the Adirondack region, Warren, Essex, and Clinton Cos., in Northern N. York, while in St. Lawrence Co. the iron ore is mainly hematite; fine crystals and masses showing broad parting surfaces and yielding large pseudo-crystals are obtained at Port Henry, Essex Co.; similarly in New Jersey; in Canada, in Hull, Grenville, Madoc, etc.; at Cornwall in Pennsylvania, and Magnet Cove, Arkansas. It occurs also in *N. York*, in Saratoga, Herkimer, Orange, and Putnam Cos.; at O'Neil mine, Orange Co., in crystals; at the Pine Swamp mine, Greenwood, in masses with distinct parting; at the Tilly Foster iron mine, Brewster, Putnam Co., in crystals and massive accompanied by chondrodite, etc. In *Maine*, Raymond, Davis's Hill, in an epidotic rock; at Marshall's island, masses strongly magnetic. In *N. Hampshire*, at Franconia, in epidote and quartz; at Swanzey near Keene, and Unity. In *Vermont*, at Marlboro', Rochester, Bethel, and Bridgewater, in crystals in chlorite slate. In *Conn.*, at Haddam, in crystals, etc. In *N. Jersey*, at Hamburg, near Franklin Furnace and elsewhere. In *Penn.*, at Goshen, Chester Co., and at the French Creek mines; at Webb's mine, Columbia Co.; in dendritic delineations forming hexagonal figures, in mica at Pennsbury and New Providence. In *Maryland*, at Deer Creek. Good lodestones are obtained at Magnet Cove, Arkansas.

In *California*, in Sierra Co., abundant, massive, and in crystals; in Plumas Co.; Mariposa Co., east of the Mariposa estate, on the trail to the Yosemite; Placer Co., Utt's ranch; Los Angeles Co., at Cañada de las Uvas; El Dorado Co., near the Boston copper mine, in oct., and at the El Dorado Excelsior copper mine. In Washington, in large deposits.

Named from the loc. *Magnesia*, bordering on Macedonia. But Pliny favors Nicander's derivation from Magnes, who first discovered it, as the fable runs, by finding, on taking his herds to pasture, that the nails of his shoes and the iron ferrule of his staff adhered to the ground.

**Alt.**—By deoxidation through organic matter changed to protoxide, which may become a carbonate or siderite. By oxidation becomes iron sesquioxide or hematite.

**Artif.**—Formed in crystals by the action of hydrochloric acid on the sesquioxide heated, producing a partial deoxidation (Deville); by decomposition of the sesquioxide with boracic acid (Deville and Caron); by the action of iron upon alkaline sulphates (Gorgeu, Bull. Soc. Min., **10**, 174, 1887); also by a variety of other methods.

*Dimagnetite* of Shepard (Am. J. Sc., **13**, 392, 1852) appears to be a magnetite pseudomorph, perhaps after ilvaite. See 5th Ed., p. 151. From Monroe, Orange Co., N. Y.

**Ref.**—[1] Mlr., Min., p. 259; *z*, *y* by Breithaupt. A summary with authorities is given by Brugnatelli, Zs. Kr., **14**, 237, 1888. Scheibe notes 511, 11·9·7, 11·7·0, but gives no measurements, Zs. G. Ges., **38**, 469, 1886; also Brögger (861, 8-$\frac{4}{3}$)? from the Brevik region, Zs. Kr., **16**, 59, 1890. Russl., **8**, 226. [5] Svr., Zs. Kr., **1**, 230, 1877. [6] Cathrein, Scalotta, Zs. Kr., **8**, 219, **9**, 365, 1884. [7] Brugnatelli, Alps, l. c. [8] Flink, Nordmark, Ak. H. Stockh., Bih., **13** (2), 7, 39, 1888; he earlier mentions the vicinal planes 46·9·0, 55·9·9, and 92·9·9, ib., **12** (2), 2, 14. [9] Cathrein, Zs. Kr., **12**, 47, 1886, Min. Mitth., **10**, 53, 1888; Mgg., Jb. Min., **1**, 244, 1889; Kemp, Am. J. Sc., **40**, 62, 1890. [10] Becke, Min. Mitth., **7**, 200, 1885; **9**, 1, 1887.

NICKEL OXIDE. The occurrence of a niccoliferous sand in the gold-washings of the Fraser river, British Columbia, is noted by James Blake (Proc. Cal. Acad., **5**, 200, 1874). It occurs with magnetic-iron sand, from which it is distinguished by its yellow color, resembling pyrite. It is inferred to have the composition $Ni_3O_4$ or $NiO.Ni_2O_3$, analogous to magnetite.

This compound has been formed artificially by Baubigny in regular octahedrons of a gray color, non-magnetic. C. R., **87**, 1082, 1878.

**238. MAGNESIOFERRITE.** Magnoferrit *Rammelsberg*, Pogg., **107**, 451, 1859. Magneferrit *Kenng.*, Ueb. J., 98, 1859, 96, 1860.

Isometric. In octahedrons, and octahedrons with truncated edges.

H. = 6–6·5. G. = 4·568–4·654. Luster, color, and streak as in magnetite. Strongly magnetic.

**Comp.**—$MgFeO_4$ or $MgO.Fe_2O_3$ = Magnesia 20, iron sesquioxide 80 = 100.

Analyses, see 5th Ed., p. 152.

**Pyr., etc.**—B.B. like hematite. Difficultly soluble in hydrochloric acid.

**Obs.**—Formed about the fumaroles of Vesuvius, and especially those of the eruption of 1855, as observed by Scacchi, who particularly described the crystals and their associations. The laminæ of hematite intersecting the octahedrons have rhombohedral planes on their edges. Crystals of hematite occur at the same fumaroles. These crystals have been also described by Rath, Jb. Min., 386, 1876.

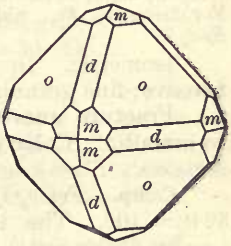
Rammelsberg first detected the magnesian nature of the crystals, and, in allusion to it, named the species *magnoferrite.* But *magno* has its own different signification in Latin; and the word should be *magnesioferrite.*

**Artif.**—Formed in crystals by heating together $Fe_2O_3$ and MgO, and subjecting to the action of hydrochloric acid vapor (Deville).

### 239. FRANKLINITE. Francklinite *Berthier*, Ann. Mines, **4**, 489, 1819.

Isometric. Observed forms:

*a* (100, *i-i*); *d* (110, *i*); *o* (111, 1); *p* (221, 2); *m* (311, 3-3).



Habit octahedral; edges often rounded, and crystals passing into rounded grains. Massive, granular, coarse or fine to compact.

Pseudo-cleavage, or parting, octahedral, as in magnetite. Fracture conchoidal to uneven. Brittle. H. = 5·5–6·5. G. = 5·07–5·22. Luster metallic, sometimes dull. Color iron-black. Streak reddish brown or black. Opaque. Slightly magnetic.

**Comp.**— (Fe,Zn,Mn)O.$(Fe,Mn)_2O_3$, but varying rather widely in the relative quantities of the different metals present, while conforming to the general formula of the spinel group.

**Anal.**—1, 2, Seyms, Am. J. Sc., **12**, 210, 1876. 3–6, Stone, Sch. Mines Q., **8**, 150, 1887. Also 5th Ed., p. 152.

| | | $Fe_2O_3$ | $Mn_2O_3$ | ZnO | MnO | FeO | |
|---|---|---|---|---|---|---|---|
| 1. Mine Hill, N. J. | | $\frac{2}{2}$ 63·40 | 4·44 | 23·12 | 10·46 | — | = 101·42 |
| 2. Sterling Hill, N. J. | | $\frac{4}{4}$ 67·42 | — | 6·78 | 9·53 | 15·65 | $Al_2O_3$ 0·65 = 100 04 |

| 4. " " | G. = 5·136 | 56·57 | 10·52 | 15·91 | 16·37 | — | = 99·37 |
| 5. Sterling Hill | G. = 5·215 | 67·38 | — | 16·28 | 16·38 | — | = 100·04 |
| 6. " " | G. = 5·074 | 66·34 | — | 20·26 | 12·31 | — | = 98·91 |

**Pyr., etc.**—B.B. infusible. With borax in O.F. gives a reddish amethystine bead (manganese), and in R.F. this becomes bottle-green (iron). With soda gives a bluish green manganate, and on charcoal a faint coating of zinc oxide, which is much more marked when a mixture with borax and soda is used. Soluble in hydrochloric acid, sometimes with evolution of a small amount of chlorine.

**Obs.**—Occurs in cubic crystals near Eibach in Nassau; in amorphous masses at Altenberg, near Aix-la-Chapelle.

Abundant at Mine Hill, Franklin Furnace, N. J., with willemite and zincite in granular limestone; also at Sterling Hill, two miles distant, where it is associated with willemite, in a large vein, in which cavities occasionally contain crystals from one to four inches in diameter.

**Artif.**—Formed in crystals by action of ferric chloride and zinc chloride on lime, with heat (Daubrée).

### 240. JACOBSITE. *Damour*, C. R., 69, 168, 1869. Jakobsit. Manganomagnetit *Flink*, Ak. H. Stockh. Bihang, 12 (2), 2, 20, 1886.

Isometric; in distorted octahedrons. Also in cleavage forms bounded by planes which seem to correspond to the hexoctahedron (60·50·3, 20-$\frac{5}{3}$)'.

H. = 6. G. = 4·75. Luster metallic, brilliant. Color deep black. Streak blackish brown. Magnetic.

**Comp.**—(Mn,Mg)O.$(Fe,Mn)_2O_3$.

**Anal.**—1, Damour, l.c., and Rg., Min. Ch., 132, 1875. 2, Lindström, G. För. Förh., **3**, 384, 1877. 3, Flink, l. c. 4, Igelström, G. För. Förh., **12**, 137, 1890.

| 4. Glakärn | | 57·55 | | 36·74[a] | 0·72 | insol. 6·02 = 101·03 |

[a] With some $Mn_2O_3$.

**Pyr.**—B.B. infusible. It does not lose weight when ignited. With the fluxes reacts for iron and manganese. Soluble in hydrochloric acid, with a slight evolution of chlorine.

**Obs.**—From Jakobsberg, in Nordmark, Wermland, Sweden, where it occurs associated with white mica and native copper in a crystalline limestone; also at Långban, Wermland, with tephroite and calcite; at the Sjö and also the Glakärn mine, Örebro.

**Ref.**—[1] Flink, l. c., anal. 3.

**241. CHROMITE.** Fer chromaté aluminé (fr. Var) *Vauq.*, Bull. Soc. Philom. 55, 57, 1800. Eisenchrom (fr. Ural) *Meder*, Crell's Ann., **1**, 500, 1798; *Karst.*, Tab., 56, 79, 1800, 74, 1808. Fer chromaté *H.*, Tr., **4**, 1801. Chromate of Iron, Chromic Iron. Chromsaures Eisen, Chromeisenstein *Germ.*, Eisenchrome *Beud.*, 1832. Siderochrome *Huot.*, **1**, 287, 1841. Chromoferrite *Chapm.*, Min., 1843. Chromit *Haid.*, Handb., 550, 1845. Chromjernmalm *Swed.* Fer chromé, Fer chromaté, *Fr.* Siderocromo, Cromite, Cromoferrite, Ferro cromato, *Ital.* Hierro cromado *Span.*

Isometric. In octahedrons; also with *d* (110, *i*), *m* (311, 3-3). Commonly massive; fine granular to compact.

Fracture uneven. Brittle. H. = 5·5. G. = 4·32–4·57. Luster submetallic to metallic. Color iron-black to brownish black, sometimes yellowish red in thin sections. Streak brown. Translucent to opaque. Sometimes feebly magnetic.

**Comp.**—$FeCr_2O_4$ or $FeO,Cr_2O_3$ = Chromium sesquioxide 68·0, iron protoxide 32·0 = 100. The iron may be replaced by magnesium as in magnochromite (magnesiochromite) below; also the chromium by aluminium and ferric iron. The varieties containing but little chromium (up to 10 p. c.) are hardly more than varieties of spinel and are classed under picotite.

Analyses: see 5th Ed., p. 153; Rg., Min. Ch., 141–144, 1885, etc. For an exhaustive table of the analyses which have been published, see Wadsworth, Lithological Studies, 1884, Mem. Mus. Comp. Zool., **11**, Pt. 1.

**Pyr., etc.**—B.B. in O.F. infusible; in R.F. slightly rounded on the edges, and becomes magnetic. With borax and salt of phosphorus gives beads which, while hot, show only a reaction for iron, but on cooling become chrome-green; the green color is heightened by fusion on charcoal with metallic tin.

Not acted upon by acids, but decomposed by fusion with potassium or sodium bisulphate.

**Obs.**—Occurs in serpentine, forming veins, or in embedded masses. It assists in giving the variegated color to verde-antique marble. Not uncommon in meteoric irons, sometimes in nodules as in the Coahuila iron, less often in crystals (Lodran).

Occurs in the Gulsen mountains, near Kraubat in Styria; in crystals in the islands of Unst and Fetlar, in Shetland; in the province of Trondhjem in Norway; in the Department du Var in France; in Silesia and Bohemia; abundant in Asia Minor (Am. J. Sc., **7**, 285, 1849); in the Eastern and Western Urals; in New Caledonia, affording ore for commerce.

At Baltimore, Md., in the Bare Hills, in large quantities in veins or masses in serpentine; also in Montgomery Co., 6 m. north of the Potomac; at Cooptown, Harford Co., and in the north part of Cecil Co., Md. In Pennsylvania, in W. Goshen (crystals), Nottingham, Mineral Hill, and elsewhere; Chester Co., near Unionville, abundant; at Wood's Mine, near Texas, Lancaster Co., very abundant. Massive and in crystals at Hoboken, N. J., in serpentine and dolomite; in the south-western part of the town of New Fane, and in Jay, Troy, and Westfield, Vt.; Chester and Blanford, Mass. In California, in Monterey Co.; also Santa Clara Co., near the N. Almaden mine. On I. à Vache, near San Domingo; at Bolton and Ham, Quebec, Canada.

The two following are properly varieties of chromite:

CHROMPICOTITE *T. Petersen*, J. pr. Ch., **106**, 137, 1869. From the dunyte of Dun Mt., New Zealand. H. = 8. G. = 4·115. Color black. Analysis, Petersen and Senfter: $Cr_2O_3$ 56·54, $Al_2O_3$ 12·13, FeO 18·01, MgO 14·08, MnO 0·46, CoO, NiO *tr.* = 101·22.

MAGNOCHROMITE *Bock* [Inaug. Diss., Breslau 1868], *Websky*, Zs. G. Ges., **25**, 394, 1873. Alumisches Eisenerz *Breith.*, Char., 234, 1832. A magnesian variety of chromite from Grochau, Silesia. Analysis, Bock, after deducting assumed impurities: $Cr_2O_3$ 40·78, $Al_2O_3$ 29·92, FeO 15·30, MgO 14·00 = 100.

---

IRITE *Herm.*, J. pr. Ch., **23**, 276, 1841. Described by Hermann as occurring in the Urals in black shining octahedrons, with G. = 6·506, and as consisting of: Iridium 56·04, osmium 9·53, iron 9·72, chromium 9·40, traces of manganese, with a loss of 15·25, which he reckoned as oxygen. But Claus has shown that the mineral is only a mixture of iridosmine, chromite, etc. (ib., **80**, 285, 1860).

PLUMBOFERRITE *L. J. Igelström*, Öfv. Ak. Stockh., **38**, No. 8, 27, 1881.

In cleavable masses. H. = 5. Color nearly black. Streak red, like hematite. Acts very feebly on the magnet. Analysis, deducting 8 p. c. $CaCO_3$:

$Fe_2O_3$ 60·38 PbO 23·12 FeO 10·68 MnO 2·20 MgO 1·95 CaO 1·67 = 100

For this the composition $2FeO.Fe_2O_3.PbO.Fe_2O_3$ is suggested. Dissolves readily in hydrochloric acid with evolution of chlorine and formation of lead chloride.

Found at the Jakobsberg manganese mine, Nordmark, Wermland, Sweden; it occurs in narrow veins in a granular limestone, associated with jacobsite.

---

**242. CHRYSOBERYL.** [Not Chrysoberyl (= var. Beryl) of *the Ancients.*] Krisoberil *Wern.*, Bergm. J., 373, 387, 1789; 84, 1790. Chrysoberyll *Karsten, Lenz*, etc. Cymophane *H.*, J. Mines, 4, 5, 1798. Alexandrite *Nordenskiöld*, Schr. Min. Ges., St. Petersb., 1842. Alaunerde + Kieselerde *Klap.*, Beitr., 1, 97, 1795; *Arfvedson*, Ak. H. Stockh., 1822. Aluminate of Glucina, mainly, *Seybert*, Am. J. Sc., 8, 105, 1824; *Bergemann*, De Chrys., Gött., 1826.

Orthorhombic. Axes $\breve{a} : \bar{b} : \dot{c} = 0{\cdot}47006 : 1 : 0{\cdot}58002$ Haidinger[1].
$100 \wedge 110 = 25° \ 10\tfrac{1}{2}'$, $001 \wedge 101 = 50° \ 58\tfrac{2}{3}'$, $001 \wedge 011 = 30° \ 6\tfrac{1}{2}'$.

**Forms**[2]:

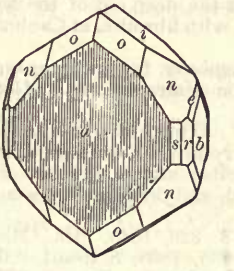
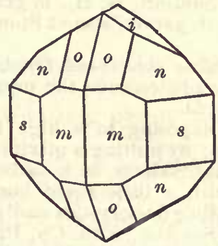
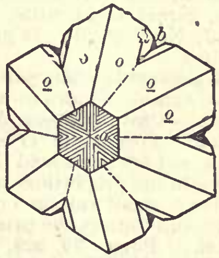
1.



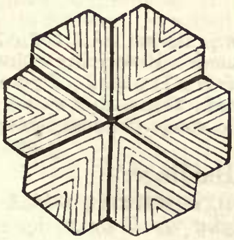
2.



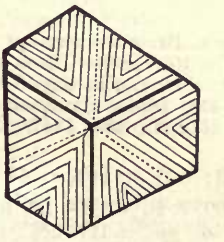
3.



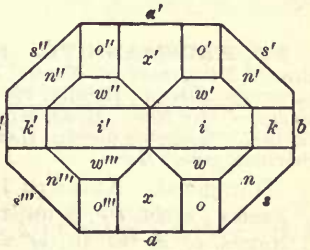
4.



5.



6.



1, Norway, Me. 2, Alexandrite, Cathrein. 3, do., Kk. 4, 5, Haddam: 6, Alexandrite, after Klein.

Twins: tw. pl. *ρ* (031), both contact- and penetration-twins; often repeated and forming pseudo-hexagonal crystals with or without re-entrant angles[4]. Crystals generally tabular ∥ *a*. Face *a* striated vertically, in twins a feather-like striation, cf. f. 3–5.

Cleavage: *i* (011) quite distinct; *b* imperfect, *a* more so. Fracture uneven to conchoidal. Brittle. H. = 8·5. G. = 3·5–3·84. Luster vitreous. Color asparagus-green, grass-green, emerald-green, greenish white, and yellowish green; greenish brown; yellow; sometimes raspberry- or columbine-red by transmitted light. Streak uncolored. Transparent to translucent. Sometimes a bluish opalescence or chatoyancy, and asteriated. Pleochroic, vibrations ‖ $\mathfrak{b}$ ($= \bar{b}$) orange yellow, $\mathfrak{c}$ ($= \dot{c}$) emerald-green, $\mathfrak{a}$ ($= \breve{a}$) columbine-red, cf. Haid., l. c. Optically +. Ax. pl. ‖ *b*. Bx ⊥ *c*. Indices:

$$\alpha = 1{\cdot}7470 \quad \beta = 1{\cdot}7484 \quad \gamma = 1{\cdot}7565 \quad \therefore\ 2V = 45^\circ\ 20' \quad 2E = 84^\circ\ 43'$$

The measured axial angles vary widely because of want of homogeneity. Elevation of temperature causes the axes to unite and open again in a plane ‖ *c*, Dx.[5]

**Var.** 1. *Ordinary.*—Color pale-green, being colored by iron; also yellow and transparent and then used as a gem. G. = 3·597, Haddam; 3·734, Brazil; 3·689, Ural, Rose; 3·835, Orenburg, Kk.

2. *Alexandrite.*—Color emerald-green, but columbine-red by transmitted light; valued as a gem. G. = 3·644, mean of results, Kk. Supposed to be colored by chromium. Crystals often very large, and in twins, like fig. 3, either six-sided or six-rayed.

3. *Cat's Eye.*—Color greenish and exhibiting a fine chatoyant effect; from Ceylon.

**Comp.**—Beryllium aluminate, $BeAl_2O_4$ or $BeO.Al_2O_3$ = Alumina 80·2, glucina 19·8 = 100.

Analyses, see 5th Ed., p. 156.

**Pyr., etc.**—B.B. alone unaltered; with soda, the surface is merely rendered dull. With borax or salt of phosphorus fuses with great difficulty. With cobalt solution, the powdered mineral gives a bluish color. Not attacked by acids.

**Obs.**—In Minas Geraes, Brazil, and also in Ceylon, in rolled pebbles, in the alluvial deposits of rivers; at Marschendorf in Moravia; in the Ural, 85 versts from Ekaterinburg, in mica slate with beryl and phenacite, the variety *Alexandrite*, of emerald-green color, columbine-red by transmitted light; in the Orenburg district, S. Ural, yellow; in the Mourne Mts., Ireland.

In the U. S., at Haddam, Ct., in granite traversing gneiss, with tourmaline, garnet, beryl, automolite, and columbite; in the same rock at Greenfield, near Saratoga, N. Y., with tourmaline, garnet, and apatite; Orange Summit, N. H., in granite at the deep cut of the Northern railroad; Norway, Me., in granite with garnet, also at Stoneham, with fibrolite, at Canton, Peru, and Stowe.

*Chrysoberyl* is from χρυσος, *golden*, βήρυλλος, *beryl*. *Cymophane*, from κῦμα, *wave*, and φαίνω, *appear*, alludes to a peculiar opalescence the crystals sometimes exhibit. *Alexandrite* is after the Czar of Russia, Alexander II.

**Artif.**—Formed in crystals by exposing to a high heat a mixture of 6 of alumina, 1·62 glucina, and 5·0 boric acid (Ebelman); by putting a mixture of beryllium fluoride and aluminium fluoride, in the proportions of their equivalents, in a carbon crucible, and at the center of the fluorides a small carbon crucible with a little fused boric acid, and heating for some hours (Deville and Caron), the process yielding fine crystals easily.

Blättricher Schwarz-Braunstein *Hausm.*, Handb., 293, 1813. Manganèse oxydé hydraté *H.*, Tr., 1822. Pyramidal Manganese Ore *Haid.*, Mohs, Min., **2**, 416, 1824. Hausmannite *Haid.*, Trans. R. Soc. Ed., **11**, 127, 1827. Glanzbraunstein *Hausm.*, Handb., 405, 1847. L'oxyde rouge de manganèse *Fr.* Scharfmanganerz *Germ.*

Tetragonal. Axis $\dot{c} = 1{\cdot}1743$; $001 \wedge 101 = 49^\circ\ 35'$ Haidinger[1].

**Forms**[2]: *c* (001, *O*)[3]; *e* (101, 1-*i*); *s* (113, $\frac{1}{3}$), *σ* (112, $\frac{1}{2}$)[3], *p* (111, 1), *n* (221, 2)[3], *r* (313, 1–3)[3].

Angles: *ee''* = *99° 10′, *ss''* = 57° 56′, *pp''* = 117° 53½′, *ee'* = 65° 9′, *ss'* = 40° 3′, *pp'* = 74° 34′, *ep* = 37° 17′.

Twins: tw. pl. *e*, often repeated as fivelings (f. 2). Habit octahedral; faces *s* usually bright and smooth, *p* striated ‖ edge *p*/*s*, often dull. Also granular massive, particles strongly coherent.

Cleavage: *c* nearly perfect; *e*, *p* indistinct. Fracture uneven. Brittle. H. = 5–5·5. G. = 4·722, 4·856 Rg. Luster submetallic. Color brownish black. Streak chestnut-brown. Opaque.

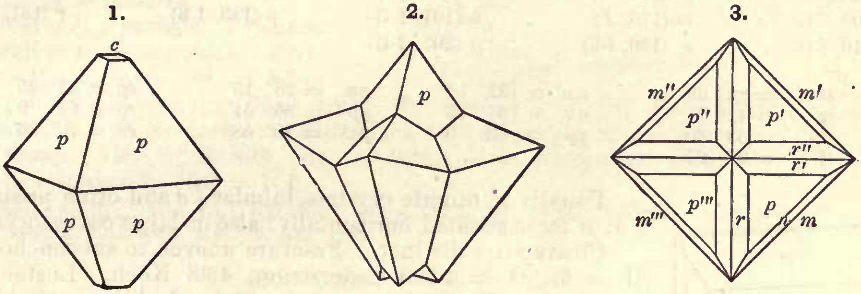
**Comp.**—$Mn_3O_4$ or $MnO.M_2O_3$ = Manganese sesquioxide 69·0, manganese protoxide 31·0 = 100.

Analyses, see 5th Ed., p. 162.

**Pyr., etc.**—B.B. like manganite. Dissolves in heated hydrochloric acid, yielding chlorine.

**Obs.**—Occurs in porphyry, along with other manganese ores, in fine crystals, near Ilmenau in Thuringia; Ilefeld in the Harz; Filipstad in Wermland, Sweden; also, as the chief vein mineral with manganosite, pyrochroite, rhodochrosite, etc., at Långban and at Nordmark; at the Sjö mine, Grythyttan. Reported from Framont in Alsace. Also reported from Lebanon, Penn. (but very doubtful, Genth).

**Artif.**—Obtained by Debray, Deville *et al.* by various methods (cf. Fouqué-Lévy, Synth. Min., 243, 1882); also by Gorgeu in crystals (G. = 4·80) by keeping fused manganese chloride for several hours in an oxidizing atmosphere saturated with water vapor, Bull. Soc. Min., **6**, 136, 1883.



1. 2. 3.

1, Långban, Flink. 2, Haidinger. 3, Långban, Flink.

**Ref.**—[1] L. c., also Ed. J. Sc., **4**, 41, 1826, and Pogg., **7**, 232, 1826. [2] Haid, l. c ; Mlr., Min., 257, 1852. [3] Flink, Långban, Ak. H. Stockh., Bih., **12** (2), No. 7, 40, 1888; he gives $pp' = 74° 14'$. See also p. 1036.

**244. MINIUM.** Mennige *Germ.* Plomb oxidé rouge *H.* Minio, Piombo ossidato rosso *Ital.* Azarcon nativo *Span., Domeyko.*

Pulverulent, occasionally exhibiting, under the microscope, crystalline scales. Also (artif.) in prismatic crystals.

H. = 2–3. G. = 4·6. Luster faint greasy, or dull. Color vivid red, mixed with yellow; streak orange-yellow. Opaque.

**Comp.**—$Pb_3O_4$ or $2PbO.PbO_2$ = Oxygen 9·4, lead 90·6 = 100.

**Pyr.**—In the reducing flame of the blowpipe, on charcoal, globules of lead are obtained.

**Obs.**—Usually associated with galena, and also with calamine, and sometimes constituting pseudomorphs after galena and cerussite.

Occurs at Bleialf in the Eifel; Badenweiler in Baden; Brillon in Westphalia; island of Anglesey; Grassington Moor and Weardale in England; Leadhills in Scotland; Zmeinogorsk mine in Siberia. Reported from Zimapan, Mexico.

In the U. S., found at Austin's mine, Wythe Co., Va., along with cerussite: reported as occurring with native lead at the Jay Gould mine. Alturas Co., Idaho; at the Rock mine, Leadville, Col., having in part the structure of the galena from which it has been derived (Hawkins).

**Artif.**—Obtained in small prismatic crystals by heating amorphous lead carbonate in a bath of potassium and sodium nitrate kept at a temperature near 300° C., Michel, Bull. Soc. Min., **13**, 56, 1890.

**245. CREDNERITE.** Kupferhaltiges Manganerz *Credner*, Jahrb. Min., 5, 1847. Mangankupferoxyd *Hausm.*, Handb., 1582, 1847. Mangankupfererz, Crednerit, *Rg.*, Pogg., **74**, 559, 1848.

Monoclinic. Foliated crystalline.

Cleavage: basal, very perfect; less distinct in two other directions obliquely inclined to one another. H. = 4·5. G. = 4·9–5·1; 4·959, 4·977 Rg. Luster metallic. Color iron-black to steel-gray. Streak black, brownish.

**Comp.**—$Cu_3Mn_4O_9$ or $3CuO.2Mn_2O_3$ (Rg.) = Cupric oxide 43·0, manganese sesquioxide 57·0 = 100.

Analyses, see 5th Ed., p. 166.

**Pyr., etc.**—B.B. fusible only on thin edges. With borax in O.F. gives a dark violet color (manganese); with salt of phosphorus a green glass, which on cooling is blue, and in R.F. becomes red (copper). Soluble in hydrochloric acid with evolution of chlorine.

**Obs.**—From Friedrichsrode, with volborthite, malachite, and manganese ores. Rammelsberg observes that this ore is undoubtedly the source of the cupreous manganese (p. 258), a secondary product.

**246. PSEUDOBROOKITE.** *A. Koch*, Min. Mitth., **1**, 77, 344, 1878.

Orthorhombic. Axes $\breve{a} : \bar{b} : \acute{c}$ = 0·87776 : 1 : 0·88475 Schmidt[1].
100 ∧ 110 = *41° 16½′, 001 ∧ 101 = 45° 13⅔′, 001 ∧ 011 = 41° 30′.

**Forms:**

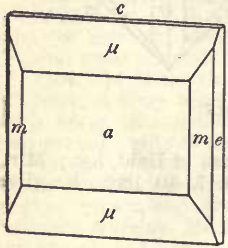
*cq* = 62° 9′
*cr* = 70° 36′



Aranyer Berg.

Usually in minute crystals, tabular ∥ *a* and often prismatic ∥ $\bar{b}$; *a* faces striated horizontally; also in large coarse crystals.

Cleavage: *c* distinct. Fracture uneven to subconchoidal. H. = 6. G. = 4·390 Cederström, 4·98 Koch. Luster adamantine; on the fracture greasy. Color dark brown to black, nearly opaque; on thinnest edges red, translucent. Streak ocher-yellow or reddish brown. Optically +. Ax. pl. ∥ *b*. Bx ⊥ *a*. Dispersion $v > \rho$. Axial angle: 2H = 84° 30′ Lattermann[5].

**Comp.**—Probably $Fe_4(TiO_4)_3$ or $2Fe_2O_3.3TiO_2$ = Titanium dioxide 42·9, iron sesquioxide 57·1 = 100, Cederström.

**Anal.**—1, Koch, on 0·1 gr., Min. Mitth., **1**, 344, 1878. 2, Lattermann, Min. Mitth., **9**, 47, 1887. 3, Cederström, Zs. Kr., **17**, 133, 1889.

| | | $TiO_2$ | $Fe_2O_3$ | MgO | |
|---|---|---|---|---|---|
| 1. Aranyer Berg | G. = 4·98 | 52·74 | 42·29[a] | [4·28[b]] | ign. 0·69 = 100 |
| 2. Katzenbuckel | | $\frac{2}{2}$ 46·79 | 48 64 | 4·53 | = 99·96 |
| 3. Bamle | G. = 4·39 | 44·26 | 56·42 | | = 100·68 |

[a] $Al_2O_3$ *tr.* [b] Also CaO.

**Pyr.**—B.B. nearly infusible, with the fluxes reacts for iron and titanium. Decomposed partly by boiling hydrochloric acid, wholly by sulphuric acid.

**Obs.**—Found with hypersthene (the so-called szaboite) in cavities of the andesyte of Aranyer Berg, Transylvania; with hypersthene and tridymite in the trachyte of Riveau Grand, Mt. Dore, Puy-de-Dôme; in the nephelinyte of the Katzenbuckel in the Odenwald; with the apatite from Jumilla, Spain; in andesyte from Berings Is.; on recent lava (1872) from Vesuvius.

In large crystals several inches long, prismatic ∥ $\bar{b}$, at Havredal, Bamle, Norway, embedded in kjerulfine (wagnerite) altered to apatite, also associated with quartz, feldspar, titanic iron (Bgr., G. För. Förh., **10**, 21, 1888, Cederström, l. c.).

**Ref.**—[1] Aranyer Berg [Term. Füz., **4**, No. 4, 1880], Zs. Kr., **6**, 100. The position taken is that originally proposed by Groth showing relation to brookite, ibid., **3**, 306, 1879; with Koch, Groth, 1889, and others, the axes $\bar{b}$ and $\acute{c}$ as here taken are interchanged. The angles vary rather widely, see Koch, l. c., and Zs. Kr., **3**, 306; Lewis, Jumilla, Spain, ib., **7**, 181, 1882; Oebbeke, Mt. Dore, ib., **11**, 370, 1886.

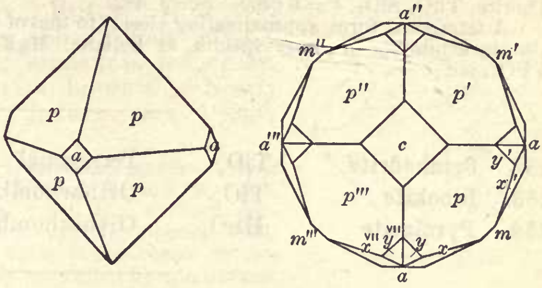
**247. BRAUNITE.** Brachytypous Manganese-Ore, Braunite, *Haid.*, Ed. J. Sc., **4**, 48, 1826, Trans. R. Soc., **11**, 137, 1827. Hartbraunstein *Hausm.*, Handb., 222, 1847. Marceline *Beud.*, **2**, 188, 1832. Heteroklin *Breith.*, Pogg., **49**, 204, 1840 (in art. by Evreinov), Handb., **3**, 801, 1847. Leptonématite. Pesillite *Adam*, Tabl. Min., 75, 1869.

Tetragonal. Axis $\dot{c} = 0{\cdot}9850$; $001 \wedge 101 = 44° 34'$ Haidinger[1].

**Forms**[1]: *c* (001, *O*); *a* (100, *i-i*)[3], *m* (110, *I*)[3], *e* (101, 1-*i*)[2] as tw. pl., *p* (111, 1), *s* (221, 2) *y* (423, $\frac{4}{3}$-2)[4], *x* (421, 4-2).

Angles: $cp = 54° 19\frac{1}{2}'$, $cs = 70° 15'$, $cx = 77° 13'$, $pp'' = {*}108° 39'$, $pp' = 70° 7'$, $ss' = 83° 27'$, $xx' = 35° 56'$, $xx^{\text{vii}} = 51° 43'$.



1, 2, Långban, Flink.

Twins: tw. pl. *e*. Commonly in octahedrons, nearly isometric in angle. Faces *c* faintly striated ‖ edge *c*/*p*; *s* uneven and striated ‖ edge *p*/*s*; *x* smooth, even. Also massive.

Cleavage: *p* perfect. Fracture uneven to subconchoidal. Brittle. H. = 6–6·5. G. = 4·75–4·82; 4·752, Elgersburg, Rg.; 4·818, ib., Haid.; 4·77, St. Marcel, Dmr. Luster submetallic. Color dark brownish black to steel-gray. Streak same.

**Comp.**—$3Mn_2O_3.MnSiO_3$ (Rg.) = Silica 10·0, manganese protoxide 11·7, manganese sesquioxide 78·3 = 100.

**Anal.**—1, Rg., Min. Ch., 160, 1875; Pogg., **124**, 515, 1865. 2, Dmr., as given by Rg., l. c. 3, Igelström, Bull. Soc. Min., 8, 421, 1885.

| | $SiO_2$ | MnO | O | CaO | |
|---|---|---|---|---|---|
| 1. Elgersburg | 8·63 | 80·94 | 8·08 | 0·91 | BaO 0·44, $H_2O$ 1·00 = 100 |
| 2. St. Marcel | 7·70 | 81·42 | [8·14] | 1·25 | $Fe_2O_3$ 1·49 = 100 |
| 3. Jakobsberg | ⅝ 8·67 | 80·23 | 8·17 | 0·95[a] | PbO 0·65, FeO 1·33 = 100 |

[a] Including MgO.

Marceline (heterocline) from St. Marcel, Piedmont, is impure braunite. Cf. Dmr., Ann. Mines, **1**, 400, 1842.

**Pyr., etc.**—B.B. infusible. With borax and salt of phosphorus gives an amethystine bead in O.F., becoming colorless in R.F. With soda gives a bluish green bead. Dissolves in hydrochloric acid evolving chlorine, and leaving a residue of gelatinous or flocculent silica (Rg.). Marceline gelatinizes with acids.

**Obs.**—Occurs both crystallized and massive, in veins traversing porphyry, at Oehrenstock, near Ilmenau; at Elgersburg in Thuringia; near Ilefeld in the Harz; at St. Marcel in Piedmont; at Elba; at Botnedal, Upper Tellemark, in Norway; at the manganese mines of Jakobsberg, Sweden, also at Långban, and at the Sjö mine, Grythyttan, and Glakärn, Örebro. At Vizianagram, Bimlipatam and elsewhere in India in large quantity (Mallet, Min. India, 55, 1887). In the Wellington district and elsewhere in New South Wales (Liversidge, Min. N. S. W., 110, 1888).

Named after Mr. Braun of Gotha.

**Ref.**—[1] Ed. J. Sc., **4**, 48, 1826, or Pogg., **7**, 234, 1826. Schuster has attempted to show that the Jakobsberg crystals belong to the rhombohedral system with tetartohedral development, but his conclusions seem very doubtful, Min. Mitth., **7**, 443, 1884. [2] Rath, Pralorgnan mine, St. Marcel, Piedmont, Ber. nied. Ges., Dec. 4, 1882; he gives $pp' = 70° 8'$ and $70° 13'$. [3] Schmidt, Maderanerthal, Zs. Kr., **11**, 603, 1886. [4] Flink, Långban, Ak. H. Stockh., Bih., **12** (2), No. 7, 38, 1888; he gives $pp' = 70° 19'$. See also p. 1029.

## IV. Dioxides, $RO_2$.

### Rutile Group. Tetragonal.

| | | | $\dot{c}$ |
|---|---|---|---|
| **248.** | **Cassiterite** | $SnO_2$ | 0·6723 |
| **249.** | **Polianite** | $MnO_2$ | 0·6647 |
| **250.** | **Rutile** | $TiO_2$ | 0·6442 |
| **251.** | **Plattnerite** | $PbO_2$ | 0·6764 |

With the Rutile group is also sometimes included:

Zircon $ZrO_2.SiO_2$ $\dot{c} = 0{\cdot}6404$.

In this work, however, Zircon is classed among the silicates, with the allied species, Thorite, $ThO_2.SiO_2$, $\dot{c} = 0{\cdot}6402$. See p. 482.

A tetragonal form, approximating closely to that of the species of the Rutile Group, belongs also to a number of other species, as Sellaite, $MgF_2$; Tapiolite, $Fe(Ta,Nb)_2O_6$; Xenotime, $YPO_4$, etc.

---

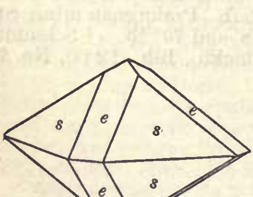
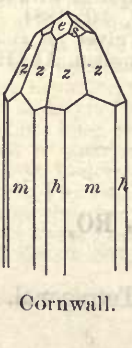
1.



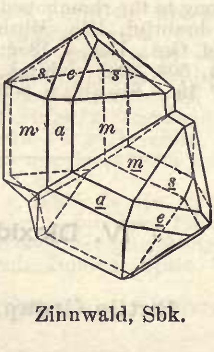
Stoneham, Me.

2.



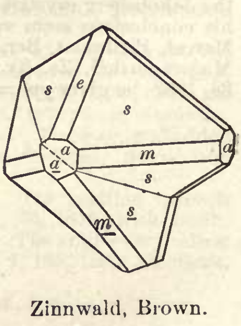
Cornwall.

3.



Zinnwald, Sbk.

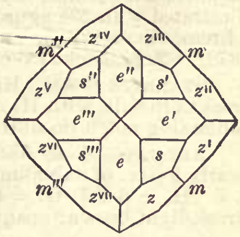
4.



Zinnwald, Brown.

Twins: tw. pl. $e$, both contact- and penetration-twins; often repeated producing complex forms, sometimes stellate fivelings. Faces $c$, $m$ often uneven; faces in zone $s$, $e$, as also those in prismatic zone, often striated parallel to their respective intersections. Often in reniform shapes, structure fibrous divergent; also massive, granular or impalpable; in rolled grains.

5.



Cornwall, Haid.

Cleavage: *a* imperfect; *s* more so; *m* hardly distinct. Fracture subconchoidal to uneven. Brittle. H. = 6–7. G. = 6·8–7·1. Luster adamantine, and crystals usually splendent. Color brown or black; sometimes red, gray, white, or yellow. Streak white, grayish, brownish. Nearly transparent to opaque. Optically +. Indices: $\omega_y = 1·9966$, $\epsilon_y = 2·0934$. Grubenmann (Rosenb.).

**Var.**—1. *Ordinary.* Tin-stone. In crystals and massive. G. of ordinary cryst. 6·96; of colorless, from Tipuani R., Bolivia, 6·832, Forbes; of honey-yellow, from Oruro, 6·704, id.; of very pure crystals from Carabuco, 6·4, id ; of black cryst. fr. Tipuani, 7·021, id. The acute pyramidal variety (f. 2) is called *needle tin ore* (Nadelzinnerz *Germ.*). The twin crystals are called by the German miners, *Zwitter*, *Zinngraupen*.

2. *Wood Tin* (Holzzinnerz *Germ.*). In botryoidal and reniform shapes, concentric in structure, and radiated fibrous internally, although very compact, with the color brownish, of mixed shades, looking somewhat like dry wood in its colors. *Toad's-eye* tin is the same, on a smaller scale. G. of one variety 6·514.

*Stream tin* is the ore in the state of sand, as it occurs along the beds of streams or in the gravel of the adjoining region. It has been derived from the wear and decomposition of the rocks carrying tin ore.

**Comp.**—Tin dioxide, $SnO_2$ = Oxygen 21·4, tin 78·6 = 100. A little $Ta_2O_5$ is sometimes present, also $Fe_2O_3$.

Analysis, by Becke, of a dark colored crystal, l. c.:

| | | | | | |
|---|---|---|---|---|---|
| Schlackenwald | $SnO_2$ 98·74 | $Fe_2O_3$ 0·12 | CaO 0·41 | $SiO_2$ 0·19 | = 99·46. |

Other analyses, see 5th Ed., p. 158, also Genth, Am. Phil. Soc., **24**, 26, 1887. Genth shows of Mexican cassiterite that the red varieties carry $Fe_2O_3$ up to 6 p. c. and more, with G. = 6·54–6·91; the yellow carry $As_2O_5$ to 10 p. c., and ZnO to 3 p. c., with G. = 6·16–6·51; these constituents are to be regarded simply as impurities.

**Pyr., etc.**—B.B. alone unaltered. On charcoal with soda reduced to metallic tin, and gives a white coating. With the fluxes sometimes gives reactions for iron and manganese. Only slightly acted upon by acids.

**Obs.**—Occurs in veins traversing granite, gneiss, mica schist, chlorite or clay schist, and porphyry; also in finely reticulated veins forming the ore-deposits called stockworks, or simply impregnating the enclosing rock. The commonly associated minerals are quartz, wolframite, scheelite, also mica, topaz, tourmaline, apatite, fluorite; further pyrite, arsenopyrite, sphalerite; molybdenite, native bismuth, etc.

Formerly very abundant, now less so, in Cornwall, in fine crystals, and also as *wood-tin* and *stream-tin;* in Devonshire, near Tavistock and elsewhere; County of Wicklow, Ireland; in pseudomorphs after feldspar at Wheal Coates, near St. Agnes, Cornwall; in fine crystals, often twins, at Schlackenwald, Graupen, Joachimsthal, and Zinnwald, etc., in Bohemia; Ehrenfriedersdorf, Altenberg, etc., in Saxony; at Limoges in splendid crystals; also in Galicia; Greenland, with cryolite at Ivigtut; Sweden, at Finbo; Finland, at Pitkäranta.

In the E. Indies, on the Malay peninsula of Malacca and the neighboring islands, Banca, and Bilitong near Borneo. In Australia, abundant, thus: In New South Wales, over an area of 8500 sq. miles, also in Victoria; in Queensland in alluvial deposits over a large area along the Severn river and its tributaries, also in numerous veins in granite. In large amount in Tasmania. In Bolivia, S. A., in the gold region along the Tipuani R.; at Oruro tin mines; and at Carabuco, Bolivia; in Mexico, in Durango; also Guanajuato, Zacatecas, Jalisco.

In the United States, in *Maine*, sparingly at Paris, Hebron, Winslow and Stoneham. In *Mass.*, at Chesterfield and Goshen, a few crystals, with albite and tourmaline. In *N. Hamp.*, at Lyme, and somewhat more abundantly in the town of Jackson. In *Virginia*, sparingly in some gold mines; also more abundantly on Irish Creek, Rockbridge Co., with wolframite, etc., Glenwood, Mason, W. Va. In *Alabama*, in Coosa Co. In *South Dakota* near Harney Peak and near Custer City in the Black Hills, where it has been mined to some extent, but with indifferent success; in the Nigger Hill district in Lawrence Co. In *Wyoming*, in Crook Co. In *Montana*, near Dillon. In *California*, in San Bernardino Co., at Temescal (see p. 1030). In *Idaho*, on Jordan creek, near Boonville.

**Artif.**—Formed in crystals by the action of a stream of hydrochloric acid gas on $SnO_2$ (Deville); by action of steam on chloride or fluoride of tin (Daubrée). Also Bourgeois, Bull. Soc. Min., **11**, 58, 1888.

**Alt.**—Substitution pseudomorphs after orthoclase, quartz, tourmaline occur in Cornwall; also after hematite and magnetite in Mexico (Genth).

**Ref.**—[1] Graupen, Bohemia, Min. Mitth., 243, 1877; Mlr. gives *ce* = 33° 55′·2 ∴ ċ = 0·6725, Min., 230; Nd., Pitkäranta, *ce* = 33° 53½′, ċ = 0·6718, Pogg., **101**, 637, 1857.
[2] Cf. Mlr., also Becke, l. c., the latter for authorities, etc.; also earlier, Hbg., Min. Not., **1**, 28, **6**, 18, 1864; Gadolin, Vh. Min. Ges., 161, 1855–56 (who adds many doubtful planes not included here); Nd., l. c. An early paper by Phillips on the Cornish forms is elaborately illustrated with 235 figures, plates 15–26, Trans. G. Soc., London, **2**, 336, 1814 [3] Becke, l. c. [4] Erem., Transbaikal, Vh. Min. Ges., **11**, 273, 1876. [5] Bodewig, Min.-Samml. Strassburg, 104, 1878. [6] Zeph., Schlackenwald, Lotos, 1880. [7] Busz, Zinnwald, Zs. Kr., **15**, 623, 1889. See p. 1030.

STANNITE *Breith.*, Handb., **3**, 772, 1847. An amorphous, pale yellowish white substance, from Cornwall, with H. = 6·5, G. = 3 545; has been regarded as a pseudomorph after feldspar, containing much tin dioxide as a mixture with the other ingredients.

AINALITE *A. E. Nordenskiöld*, Finl. Min., 162, 1855, 26, 1863. A cassiterite containing nearly 9 p. c. of tantalum pentoxide. Isomorphous with cassiterite, and presenting the planes *e*, *s*. H. = 6–6·5; G. = 6·6–6·8. Luster vitreous to adamantine; color black to grayish black; streak light brown; opaque. Analysis by Nordenskiöld:

$SnO_2$ 88·95 $Ta_2O_5$ 8·78 $Fe_2O_3$ 2·04 CuO 0·78 = 100·55

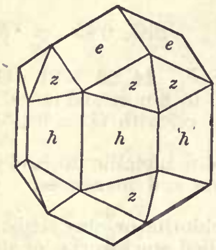
From Pennikoja in Somero, Finland, with tantalite and beryl in albite. Cf. Tapiolite, p. 738.

**249. POLIANITE.** Pyrolusite pt. Lichtes Graumanganerz *Breithaupt*, Char., 231, 1832. Polianit, *id.*, Pogg., **61**, 191, 1844.

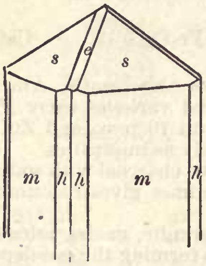
Tetragonal. Axis ċ = 0·66467; 001 ∧ 101 = 33° 36⅔′ E. S. Dana[1].

**Forms**[1]: *a* (100, *i-i*), *m* (110, *I*); *h* (210, *i*-2); *e* (101, 1-*i*), *g* (201, 2-*i*); *s* (111, 1), *n* (221, 2); *z* (321, 3-$\frac{3}{2}$).

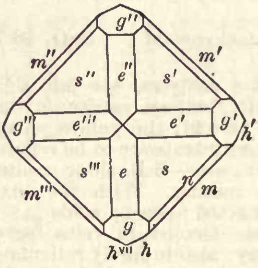
1.



2.



3.



Figs. 1–3, Platten, Bohemia.

*ah* = 26° 34′ *ee''* = 67° 13′ *ss''* = 86° 27′ $zz^{viii}$ = 45° 18′
*hh'* = 36° 52′ *gg''* = 106° 6′ *nn''* = 123° 59′ *ez* = 41° 46½′
*ee'* = 46° 5′ *ss'* = *57° 56′ *zz'* = 20° 51′ *az* = 39° 50′
*gg'* = 68° 49′ *nn'* = 77° 15½′ $zz^{vii}$ = 61° 35′ *mz* = 25° 11′

Often in composite parallel groupings of minute crystals, the resulting form having a rough summit and rhombic form. Also forming the outer shell of crystals having the form of manganite.

Cleavage: *m* perfect. Fracture uneven. Brittle. H. = 6–6·5. G. = 4·992 Pfd.; 4·838, 4·880 Breith.; 5·026 Rg. Luster metallic. Color light steel-gray or iron-gray. Streak black. Opaque.

**Comp.**—Manganese dioxide, $MnO_2$ = Oxygen 36·9, manganese 63·1 = 100.

**Anal.**—1. Plattner, Pogg., **61**, 192, 1844 and Rg., Min. Ch. 174, 1875. 2, Rg., l. c. 3, Penfield, Am. J. Sc., **35**, 247, 1888.

| | MnO | O | $Fe_2O_3$ | $SiO_2$ | $H_2O$ | insol. | |
|---|---|---|---|---|---|---|---|
| 1. G. = 4·84–4·88 | 81·17 | 18·21 | 0·17 | — | 0·32 | 0·13 | = 100 |
| 2. G. = 5·026 | 80·82 | 18·60 | — | — | — | — | = 99·42 |
| 3. G. = 4·992 | 80·81 | 18·16 | 0·16 | 0·36 | 0·28 | 0·16 | = 99·93 |

The loss by ignition in (1) was 12·43, in (2) 12·44; in another analysis by Penfield 12·42, with only a trace of $H_2O$. Plattner's analysis gave: $Mn_3O_4$ 87·27, O 12·11.

**Pyr.**—B.B. alone infusible; on charcoal loses oxygen· the usual reactions for manganese with the fluxes. Evolves chlorine when treated with hydrochloric acid.

**Obs.**—Occurs at Platten, Bohemia. It is distinguished from pyrolusite, with which it has often been confounded (though the distinction was insisted upon by Breithaupt) by its hardness and its anhydrous character. Like pyrolusite it is often a pseudomorph after manganite. The name refers to the gray color, from *πολιαίνεσθαι, to become gray*.

**Ref.**—[1] Am. J. Sc., **35**, 243, 1888. The form was earlier regarded as orthorhombic, but only imperfectly made out. Cf. also Breith., l. c., and Köchlin, Min. Mitth., **9**, 29, 1887.

Twins[10]: tw. pl. (1) *e*, often geniculated; also contact-twins of very varied habit, sometimes sixlings and eightlings. (2) *v* (301) rare, contact-twins (f. 9); rarely both methods observed in the same crystal; sometimes shows tw. lamellæ[11] ‖ *e*, also[11] ‖ 902. Crystals commonly prismatic, vertically striated or furrowed; often slender acicular. Occasionally compact, massive.

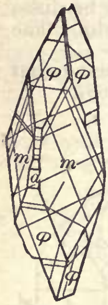
Cleavage: *a* and *m* distinct; *s* in traces. Parting due to twinning ‖ 902[11]. Fracture subconchoidal to uneven. Brittle. H. = 6–6·5. G. = 4·18–4·25; also to 5·2. Luster metallic-adamantine. Color reddish brown, passing into red; sometimes yellowish, bluish, violet, black, rarely grass-green; by transmitted light deep red. Streak pale brown. Transparent to opaque. Optically +. Double refraction strong. Refractive indices high: $\omega_y$ = 2·6158, $\epsilon_y$ = 2·9029 for Na, Bärwald[12]. Sometimes abnormally biaxial, cf. Mld[13].

**Comp., Var.**—Titanium dioxide, $TiO_2$ = Oxygen 40·0, titanium 60·0 = 100. A little iron is usually present, sometimes up to 10 p. c.

**Var.**—1. *Ordinary.* Brownish red and other shades, not black. G. = 4·18–4·25. Transparent quartz is sometimes penetrated thickly with acicular or capillary crystals, and this variety is the *Sagenite* (fr. *σαγήνη*, a net), also named *Crispite*. Dark smoky quartz penetrated with the acicular rutile is apparently the *Veneris crinis* of Pliny (Flêches d'amour *Fr.*, or Venus hair-stone). Acicular crystals often implanted in parallel position on tabular crystals of hematite; also somewhat similarly on magnetite.

*Edisonite* (l. c.) was supposed to be an independent orthorhombic form of $TiO_2$, though approximating closely in angle to rutile ("un mineral qui paraît offrir une forme dimorphe du rutile," Dx., Bull. Soc. Min., 9, 184, 1886). There can be no doubt, however, that it is similar to the forms from the Ural and from Snarum (f. 2), described by Mügge[11], peculiar in showing a parting ‖ $\phi$ (902), $\phi\phi^{iv}$ ($902 \wedge 90\bar{2}$) = 38° 4′. Found very sparingly in the gold washings of Polk Co., N. C. Named after the inventor, Thomas A. Edison.

2.



3.

2, Form with parting ‖ 902, Mgg. 3, Pseudomorph after hematite, Binnenthal, Rath.

2. *Ferriferous.* (*a*) *Nigrine.* Color black, whence the name. Contains 2 to 3 p. c. of $Fe_2O_3$. But as ordinary rutile has 1 to 2 p. c., the distinction is very small. G. = 4·249, Oláhpian; 4·242 Freiberg. A jet-black rutile from St. Peter's Dome, Colorado, with 3·77 p. c. FeO (Eakins), and G. = 4·288, belongs here, cf. W. B. Smith, Proc. Col. Soc., 2, 175, 1887. Another black rutile from Colorado closely resembles common twins of cassiterite.

(*b*) *Ilmenorutile.* A black variety from the Ilmen Mts., containing up to 10 p. c. or more of $Fe_2O_3$, and having G. = 5·074–5·133. Cf. Erem.[3], also Kk., Min. Russl., 5, 193.

A black rutile occurring in the granite of the Black Hills, Dakota, is in twin crystals, prismatic and orthorhombic in habit by extension of two pyramidal faces (*s*); it has G. = 5·29-5·31, and contains 8·01 p. c. FeO and 1·35 $SnO_2$ according to W. P. Headden (Am. J. Sc., 41, 249, 1891). A similar form has been described by Miklucho-Maclay, Jb. Min., 2, 88, 1885.

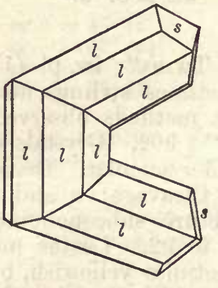
10.



Figs. 4, 5, Common forms. 6, Magnet Cove, Rath. 7, 8, Graves Mt., Rose. 9, Alexander Co., N. C., Rath. 10, Geniculated twin.

3. *Chromiferous.* Titane oxydé chromifère *H.* A grass-green variety, containing chrome, which gives the color Cf. below, also Arzruni, Zs. Kr., 8, 334, 1883.

**Pyr., etc.**—B.B. infusible. With salt of phosphorus gives a colorless bead, which in R F assumes a violet-color on cooling. Most varieties contain iron, and give a brownish yellow or red bead in R.F., the violet only appearing after treatment of the bead with metallic tin on charcoal. Insoluble in acids; made soluble by fusion with an alkali or alkaline carbonate. The solution containing an excess of acid, with the addition of tin-foil, gives a beautiful violet color when concentrated.

**Obs.**—Rutile occurs in granite, gneiss, mica slate, and syenitic rocks, and sometimes in granular limestone and dolomite; common, as a secondary product, in the form of microlites in many slates. It is generally found in embedded crystals, often in masses of quartz or feldspar, and frequently in acicular crystals penetrating quartz; also in phlogopite (wh. see), and has been observed in diamond. It has also been met with in hematite and ilmenite, rarely in chromite. It is common in grains or fragments in many auriferous sands.

Prominent localities are: at Arendal and Kragerö in Norway; Horrsjöberg, Sweden, with lazulite and cyanite; Saualpe, Carinthia; in the Urals; in Tyrol; at St. Gothard; Binnenthal; at Yrieux, near Limoges in France; Krummhennersdorf, near Freiberg; in Castile, in geniculated crystals, often large; at Ohlapian in Transylvania, *nigrine* in pebbles; in large crystals in Perthshire, Scotland; at Crianlarich, at Craig Calleach near Killin, and on Benygloe; in Donegal Co., Ireland. A variety from Karingsbricka in Sweden contains, according to Ekeberg (Ak. H., Stockh., 46, 1803), 3 p. c. of chrome, and is the *titane oxydé chromifère* of Haüy; *grass-green* needles, supposed to be chromiferous, have been found in the Swiss Alps. The *Ilmenorutile* is from the phenacite and topaz mine of the Ilmen Mts., in the Ural.

In *Maine*, at Warren, along with tremolite and chalcopyrite. In *N. Hamp.*, sparingly at Lyme, with tourmaline; near Hanover, acicular crystals in quartz, only in loose masses. In *Vermont*, at Waterbury, Bristol, Dummerston, and Putney; also in loose bowlders in middle and northern Vermont, acicular, some specimens of great beauty in transparent quartz. In *Mass.*, at Barre, in gneiss, crystals occasionally an inch and a half in diameter; at Windsor, in feldspar veins intersecting chlorite slate; at Shelburne, in fine crystals in mica slate; at Leyden, with scapolite; at Conway, with gray epidote. In *Conn.*, at North Guilford; at Lane's mine, Monroe, and in the adjoining town of Huntington. In *N. York*, in Orange Co., 1 m. E. of Edenville, with pargasite in limestone bowlders; 2 m. E. of Warwick, in granite with zircon; 1 m. E. of Amity, in quartz with brown tourmaline, and 2 m. W., with spinel and corundum, and also 2 m. S.W., with red spinel and chondrodite; near Warwick, in slender prisms penetrating quartz; in N. York Co., at Kingsbridge, in veins of quartz, feldspar, and mica traversing granular limestone; in the limestone of Essex Co. In *Penn.*, in fine long crystals, at Sadsbury, Chester Co., and the adjoining district in Lancaster Co.; at Parksburg, Concord, West Bradford, and Newlin, Chester Co.; at the Poor House quarry, Chester Co., in delicate crystals, sometimes iridescent, on dolomite. In *N. Jersey*, at Newton, with spinel. In *N. Car.*, at Crowder's Mountain; at Stony Point, Alexander Co., in splendent crystals of varied habit with dolomite, muscovite, hiddenite, emerald, etc. In *Georgia*, in Habersham Co.; in Lincoln Co., at Graves' Mountain, with lazulite in large and splendent crystals, some $3\frac{1}{2}$ by $2\frac{3}{4}$ in. In *Arkansas*, at Magnet Cove, commonly in twins with brookite and perovskite, also as paramorphs after brookite. In *Colorado* and *Dakota*, as noted above.

In *Canada*, small crystals, with hematite at Sutton, Quebec; in the ilmenite of Bay St. Paul, orange translucent grains, pure $TiO_2$, and probably rutile or brookite.

**Artif.**—Formed in crystals by heating together to redness titanic acid and protoxide of tin, and then heating the mass with silica to a cherry-red heat (Deville); by the action of steam on fluoride or chloride of titanium (Daubrée, Hautefeuille). Hautefeuille observes that in this process crystals of *rutile* are formed when the heat used is red heat; of *brookite*, when it is between that required for volatilizing cadmium and zinc; and of octahedrite, when the heat is a little below that required for the volatilization of cadmium.

Has been observed in crystals as a furnace product by Scheerer.

**Alt.**—Observed as a paramorph after brookite, also pseudomorph after hematite. Cf. Rath, Jb. Min., 397, 1876, Zs. Kr., **1**, 13, 1877. Also altered to ilmenite, Lsx., Zs. Kr., **8**, 55, 1883.

**Ref.**—[1] Phil. Mag., **17**, 268, 1840; the measurements of Koksharov agree very closely, viz.: $ce = 32° 47' 20''$, $\dot{c} = 0·64418$, Min. Russl., **1**, 50. Zeph. obtained $ce = 32° 47'$, $\dot{c} = 0·64404$, Zs. Kr., **6**, 238, 1881. Washington obtained from fine N. Carolina crystals $ce = 32° 47' 30''$, $\dot{c} = 0·64425$, Am. J. Sc., **33**, 501, 1887. These angles show great constancy for the species.

[2] See Kk., l. c. Dx., Ann. Ch. Phys., **13**, 436, 1845. Haid., Ber. Ak. Wien, **39**, 5, 1860. Hbg., Min. Not., **1**, 30, **2**, 11, 1858, **5**, 25, 1863. Min., **1**, 221, 1884, **1**, 147, 1886, **1**, 231, 1889. [12] Zs. Kr., **7**, 167, 1882. [13] Ann. Mines, **10**, 134, 1876; cf. also Lsx., Zs. Kr., **8**, 67, 1883.

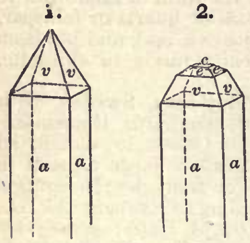
ISERITE *Janovsky*, Ber. Ak. Wien, **80** (1), 34, 1886. Found among the black grains of the so-called "iserin" of the Iserwiese, Bohemia. Distinguished from the true iserin by the absence of conchoidal fracture and the brown color. In thin fragments honey-yellow. Crystalline form like rutile, occasionally in twins; cleavage imperfect. G. = 4·52. Analysis. $TiO_2$ 69·51 ($\frac{2}{2}$), FeO 28·67 ($\frac{2}{2}$), MnO 1·41, MgO 0·32, $Nb_2O_5$, $SiO_2$ 0·44 = 100·45. This corresponds to the formula: $FeTi_2O_5$.

**251. PLATTNERITE.** Schwerbleierz *Breith.*, J. pr. Ch., **10**, 508, 1837. Plattnerit *Haid.*, Handb., 504, 1845. Braunbleioxyd *Hausm.*, Handb., 202, 1847.

Tetragonal. Axis $\dot{c} = 0{\cdot}67643$; 001 ∧ 101 = 34° 4½′ Ayres[1].



Figs. 1, 2, Idaho, Ayres.

**Forms:** *c* (001, *O*); *a* (100, *i-i*); *e* (101, 1-*i*), *v* (301, 3-*i*); *x* (332, $\frac{3}{2}$). Angles: *ee′* = 46° 41′, *vv′* = 78° 44′, *ee″* = 68° 9′, *vv″* = *127° 32′, *cx* = 55° 8′, *vx* = 39° 22′.

Rarely in crystals, habit prismatic; usually massive; sometimes in globular or mammillary forms.

Cleavage not observed. Fracture subconchoidal to uneven. Brittle. H. = 5–5·5. G. = 8·5. Luster submetallic. Color iron-black. Streak chestnut-brown. Translucent to nearly opaque. Optically negative[2].

**Comp.**—Lead dioxide, $PbO_2$ = Oxygen 13·4, lead 86·6 = 100.

**Anal.**—1, E. Kinch, Min. Mag., **7**, 63, 1886. 2, W. S. Yeates, priv. contr. Also H. A. Wheeler (G. = 9·41), Am. J. Sc., **38**, 79, 1889, and J. D. & E. N. Hawkins (G. = 7·25), ib., p. 165.

| | | Pb | O | |
|---|---|---|---|---|
| 1. Leadhills | G. = 8·54 | 86·01 | 12·85 | $H_2O, CO_2, Fe_2O_3, CaO$ *tr.* |
| 2. Idaho | G. = 8·56 | 83·20 | 12·93 | $(Fe,Al)_2O_3$ 1·71, Cu 0·14, Ag *tr.*, insol. 0·82 = 98·80. |

**Pyr.**—B.B. fuses at 2, giving off oxygen; yields metallic lead on charcoal. Soluble in acids.

**Obs.**—Described by Plattner (G. = 9·39–9·45) on specimens probably from Leadhills, Scotland, apparently pseudomorphous after pyromorphite. Later identified from Leadhills with cerussite and pyromorphite, and from Wanlockhead (G. = 9·27, Heddle). Also recently obtained, massive, rarely in crystals (figs. 1, 2), at the "As You Like" mine, Mullan, Cœur d'Alene Mts., Idaho, with pyromorphite, limonite, and quartz.

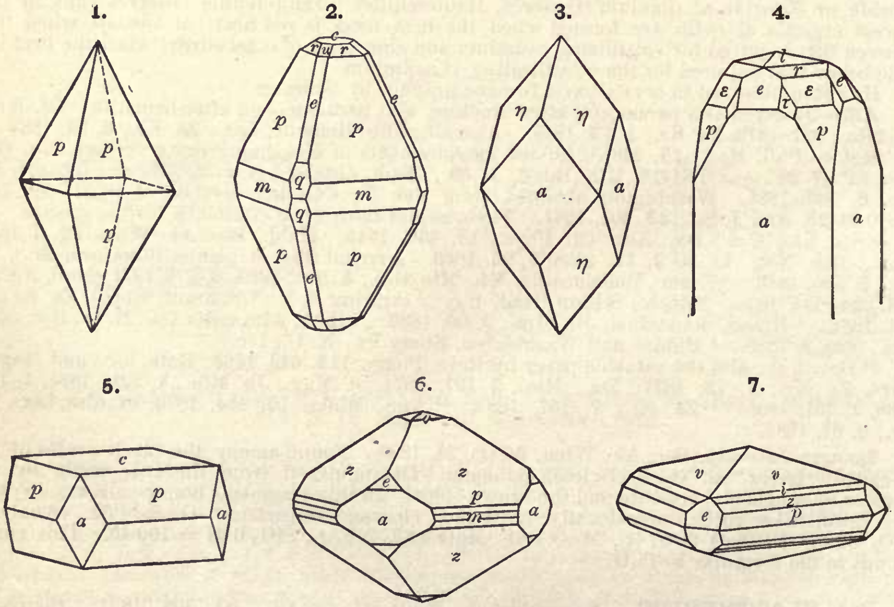
Named for the mineralogist, K. Fr. Plattner (1800–1858).

**Ref.**—[1] E. F. Ayres, priv. contr. [2] Michel, artif. cryst., Bull. Soc. Min., **13**, 56, 1890.

---

**252. OCTAHEDRITE.** Schorl bleu indigo (fr. Oisans) *Bourn.*, de Lisle's Crist., **2**, 406, 1783; Schorl octaèdre rectangulaire *id.*, J. Phys., **30**, 386, 1787. Octaëdrite *Sauss.*, Alpes, § 1901 1796. Oktaëdrit *Wern.*, 1803, Ludwig's Wern., **2**, 218, 1804. Oisanite *Delameth.*, T. T., **2**, 269, 1797; *H.*, J. Mines, **5**, 273, 1799. Anatase *H.*, Tr., **3**, 1801. Dauphinit.

Tetragonal. Axis $\dot{c} = 1{\cdot}7771$; 001 ∧ 101 = *60° 38′ Miller[1].



Figs. 1, 2, Bourg d'Oisans. 3, 4, Binnenthal, Klein. 5, Brazil, Dx. 6, Binnenthal, Zeph. 7, Binnenthal, Klein.

$\vartheta\vartheta^{vii} = 60°\ 41'$

Commonly octahedral in habit, either acute ($p$) or obtuse ($v$); also tabular, $c$ predominating; rarely prismatic crystals; frequently highly modified.

Cleavage: $c$ and $p$ perfect. Fracture subconchoidal. Brittle. H. = 5·5–6. G. = 3·82–3·95; sometimes 4·11–4·16 after heating. Luster adamantine or metallic-adamantine. Color various shades of brown, passing into indigo-blue, and black; greenish yellow by transmitted light. Streak uncolored. Transparent to nearly opaque. Optically −. Double refraction rather strong. Indices $\omega_y = 2·554$, $\epsilon_y = 2·493$ Mlr. Sometimes abnormally biaxial, cf. Mld[12].

**Comp.**—Titanium dioxide, $TiO_2$ = Oxygen 40·0, titanium 60·0 = 100.

**Pyr., etc.**—Same as for rutile.

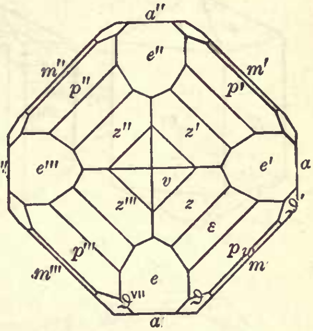
**Obs.**—Most abundant at Bourg d'Oisans, in Dauphiné, with feldspar, axinite, and ilmenite. Found in mica slate in the Grisons; in Bavaria; near Hof in the Fichtelgebirge; Norway; the Urals; in chlorite in Devonshire, near Tavistock; with brookite at Tremadoc, in North Wales; in Cornwall, near Liskeard and at Tintagel Cliffs; in Brazil in quartz, and in detached crystals so splendent as to be sometimes mistaken for diamonds.

In Switzerland in the Binnenthal the variety *wiserine*, long supposed to be xenotime, but correctly determined by Klein (l. c.); also in Cavradi, Tavetsch; Rauris, Salzburg in the Eastern Alps, also at Pfitsch Joch.

In the U. States, at the Dexter lime rock, Smithfield, R. I., in dolomite; in the washings at Brindletown, Burke Co., N. C., in transparent tabular crystals.

De Saussure's name *octahedrite* has the priority, and is particularly appropriate, the crystals being usually octahedrons. Haüy's *anatase* is No. 3 in order of time, and was brought forward after he had once adopted for a while Delametherie's name *oisanite;* it is from ἀνάτασις, *erection*, and was intended to signify, as Haüy says, that the common octahedron was longer than that of other tetragonal species; but *length* is not in the meaning of the Greek word.

8.



Binnenthal, after Zeph.

**Artif.**—Formed in crystals by the action of steam on chloride or fluoride of titanium (Daubrée); by the action of a stream of hydrochloric acid gas on $TiO_2$ (Deville); by fusing $TiO_2$ with salt of phosphorus B.B. in R.F., and then exposing the bead to the point of the blue flame, when minute transparent crystals of octahedrite separate (G. Rose).

*λ* (142, $2\text{-}\breve{4}$)[9]
*h* (151, $5\text{-}\breve{5}$)[3]

The symbol of the plane *θ* (5·14·18) has been established by several observers. Dx.[8] adds the vicinal planes near *ϵ*, *λ* (9·22·30 or 6·15·20) and *δ* (5·14·18 or 5·13·16). Schrauf[6], who makes the species monoclinic, gives $\mathfrak{e}$ (940, $i\text{-}\overline{\tfrac{9}{4}}$), $\mathfrak{a}$ (320, $i\text{-}\overline{\tfrac{3}{2}}$); $\mathfrak{r}$ (089, $\tfrac{8}{9}\text{-}\breve{\imath}$); $\pm\mathfrak{p}$ (9·4·18, $\pm\tfrac{1}{2}\text{-}\overline{\tfrac{9}{4}}$), $\pm\mathfrak{g}$ (949, $\pm 1\text{-}\overline{\tfrac{9}{4}}$); *P* (7·5·14, $-\ \tfrac{1}{2}\text{-}\overline{\tfrac{7}{5}}$); $\pm\mathfrak{r}$ (349, $\pm\ \tfrac{4}{9}\text{-}\breve{\tfrac{4}{3}}$), $\pm\mathfrak{q}$ (343, $\pm\ \tfrac{4}{3}\text{-}\breve{\tfrac{4}{3}}$); *Σ* ($\bar{2}$56, $+\ \tfrac{5}{6}\text{-}\breve{\tfrac{5}{2}}$), *Δ* ($\bar{4}$·10·1 3 $+\ \tfrac{10}{13}\text{-}\breve{\tfrac{5}{2}}$); *D* (4·11·14, $-\ \tfrac{11}{14}\text{-}\breve{\tfrac{11}{4}}$); *Ω* (1·22·12, $+\ \tfrac{11}{6}\text{-}22$).

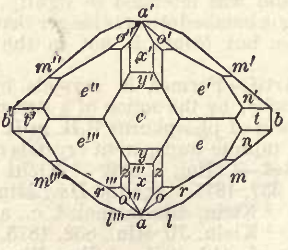
7.



Figs. 1–4, Magnet Cove, *Arkansite*[12]. 5, Ellenville. 6, Tremadoc, Rath. 7, Miask, after Kk.

Only in crystals. Habit varied, often tabular ‖ $a$; faces $a$, and prismatic faces striated vertically. Also prismatic ($m$), sometimes simulating rutile (f. 1); faces $z$, $\chi$ often striated ‖ their intersection-edge. Sometimes in forms with $e$ and $m$, nearly hexagonal (f. 4); since $me = ee'$ nearly, also $mm'''$ and $ee'''$.

Cleavage: $m$ indistinct; $c$ still more so. Fracture subconchoidal to uneven. Brittle. H. = 5·5–6. G. = 3·87–4·01 Tremadoc; 3·96, 4·07 Magnet Cove, Rath; 4·084 Magnet Cove, Pfd. Luster metallic-adamantine to submetallic. Color hair-brown, yellowish, reddish, reddish brown, and translucent; also brown to iron-black, opaque. Streak uncolored to grayish or yellowish.

Optically +. Bx ⊥ $a$. Ax. pl. for red and yellow ‖ $c$; for green and blue ‖ $b$; for yellow-green uniaxial. Rarely ax. pl. for all colors ‖ $c$ with $\rho > v$. A section ‖ $a$ shows four sets of hyperbolic bands. On heating the axes ‖ $b$ approach and those ‖ $c$ open, but temporarily only, unless this is carried carefully to a bright red heat, when the change becomes permanent, Dx.[14] Ax. angles somewhat variable for different localities; as obtained by Zepharovich and Lippich[15]:

$2E_a = 55° 2'$ red, Li 30° 16′ yellow, Na 0° yw.-green 33° 48′ green, Tl

**Var.**—1. *Ordinary.* Thin tabular crystals often highly modified, brilliant luster.

2. *Arkansite.* Stout crystals brown to iron-black; often dull, and on the surface altered by paramorphism to rutile.

**Comp.**—Titanium dioxide, $TiO_2$ = Oxygen 40·0, titanium 60·0 = 100.

**Pyr.**—Same as for rutile.

**Obs.**—Brookite occurs at Bourg d'Oisans in Dauphiné; at St. Gothard, with albite and quartz; Maderaner Thal, Switzerland; in the Ural, district of Zlatoust, near Miask, and in the gold-washings in the Sanarka river and elsewhere; near Markirch in the Vosges, in pseudomorphs after titanite; rarely at Val del Bove, Etna, with rutile; in the gneiss of Beura; at Fronolen near Tremadoc, Wales. In relatively large crystals from the Tyrol, 44 × 39 mm. (Zeph., l. c.)[11].

In the U. S., in thick black crystals (*arkansite*) at Magnet Cove, Ozark Mts., Arkansas, with elæolite, black garnet, schorlomite, rutile, etc.; in small crystals from the gold-washings of North Carolina; at the lead mine of Ellenville, Ulster Co., N. Y., on quartz (f. 5), with chalcopyrite and galena; at Paris, Maine.

Named after the English crystallographer and mineralogist, H. J. Brooke (1771–1857). Jurinite is from the naturalist L. Jurin (1751–1819) of Geneva; Arkansite from the locality.

**Alt.**—Paramorphs of rutile after brookite are not uncommon at Magnet Cove.

**Ref.**—[1] From the Ural, Vh. Min. Ges., 1848–49, 2, and Min. Russl., **1**, 61, 1853; **2**, 273. With some authors $e$ is made 111. [2] Lévy, Ann. Phil., **9**, 140, 1824. Kr., **15**, 542, 1889; also Vh. Min. Ges., **23**, 322, 1887. [15] Dx., l. c., Zeph., l. c. Cf. other observations by Zeph.; also by Schrauf, Zs. Kr., **9**, 444, 1884, who gives $2H_{a.r} = 26°–29°$. Dx. found the axial plane ‖ $c$ with $\rho > v$, for Snowdon crystals.

In addition to the several forms in which the oxide of titanium appears in nature, viz. rutile, octahedrite, brookite, also with iron oxide, ilmenite and pseudobrookite, Riggs has noted a rhombohedral form in thin iron-black scales as inclusions in the tourmaline of Hamburg and De Kalb. It seems to belong to ilmenite, but apparently contains very little iron, not becoming magnetic on heating. Am. J. Sc., **35**, 51, 1888.

EUMANITE *Shepard*, Am. J. Sc., **12**, 211, 1851. Minute crystals occurring with rubellite and microlite in the albite vein of Chesterfield, Mass., suspected to be related to brookite. On the crystalline form, see J. D. D., ib., **12**, 211, 397; **13**, 117, and Syst. Min., 5th Ed., p. 165.

**254. PYROLUSITE.** Lapis manganensis pt. *Cæsalp.*, Metall., 1596. Brunsten = Magnesia pt. *Wall*, 268, 1747; Manganese pt. *Fr. Trl.* Wall., **1**, 483, 1753. Manganaise grise pt. *Forst.*, Cat, 1772. Molybdænum magnesii *Linnæus.* Grau Braunstein pt. *Wern.*, Bergm. J., 386, 1789; id., *Hausm.*, Handb., 288, 1813 Gray Oxyd of Manganese pt.; Anhydrous Binoxyd of Manganese. Mangan Hyperoxyd *Leonh.*, Handb., 240, 1826. Pyrolusite, Prismatic Manganese-Ore, *Haid.*, Trans. R. Soc. Ed., **11**, 136, 1827. Weichbraunstein, Weichmangan, *Germ.* Peroxide of manganese. Manganese dioxide.

Orthorhombic, but perhaps only pseudomorphous (cf. below). Commonly columnar, often divergent; also granular massive, and frequently in reniform coats.

Soft, often soiling the fingers. H. = 2–2·5. G. = 4·82 Turner; 4·73–4·86 Pfd. Luster metallic. Color iron-black, dark steel-gray, sometimes bluish. Streak black or bluish black, sometimes submetallic. Opaque.

**Comp.**—Manganese dioxide, $MnO_2$, like polianite. Commonly contains a little water, it having had usually a pseudomorphous origin (after manganite).

**Anal.**—1–3, Penfield, priv. contr. 4, Jarman, Am. Ch. J., **11**, 39, 1889. Also 5th Ed., p. 166.

| | | MnO | O | $H_2O$ | |
|---|---|---|---|---|---|
| 1. Salisbury | G. = 4·785 | 79·14 | 17·27 | 2·33[a] | CaO 0·25, $SiO_2$ 0·55, L[c] 0·49 = 100·02 |

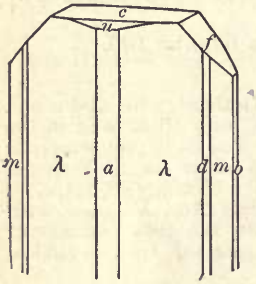
| 4. Augusta Co., Va. | G. = 4·69 | 78·77 | 17·61 | 2·08 | X[d] 1·91 = 99·87 |

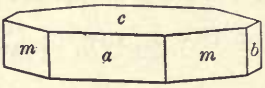
[a] Incl. loss at 100°, 0·18, 0·15, 0·17. [b] Incl. 0·38 BaO. [c] L = Limonite.
[d] X = CaO, NiO, CoO, $K_2O$, $Na_2O$, $Fe_2O_3$, insol.

It is uncertain whether pyrolusite is an independent species, with a crystalline form of its own, or only a secondary mineral derived chiefly from the dehydration of manganite; also from polianite (Breith.). Pseudomorphous crystals having distinctly the form of manganite are common (f. 1). Forms have been attributed to pyrolusite in part with prismatic angles of manganite (*mm'''* = 80°), in part with *mm'''* = 86° 20′ Haid. Crystals from Salisbury, Conn., have the form of fig. 2, with *mm'''* ≐ 84° 30′, and another prism, *n*, with *nn'''* = 73° 20; often in skeleton forms, f. 3. Cf. also Köchlin, Min. Mitth., **9**, 34, 1887; and earlier, Haid., l. c.

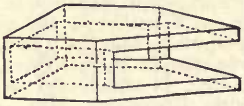
1.



2.



3.



1, Pseudomorph after manganite, Nova Scotia.
2, 3, Pyrolusite, Salisbury, Conn.

**Pyr., etc.**—Like polianite, but most varieties yield some water in the closed tube.

**Obs.**—This ore is extensively worked at Elgersberg near Ilmenau, and other places in Thuringia; at Vorderehrensdorf near Mährish-Trübau, in Moravia, which place annually affords many hundred tons of the ore; at Platten in Bohemia, and elsewhere; near Johanngeorgenstadt; at Hirschberg in Westphalia; Matzka, Transylvania; also found sparingly in Cornwall; in Timor; in Australia; in India.

Occurs in the United States with psilomelane, abundantly in Vermont, at Brandon, Irasburg, Bennington, Monkton, Chittenden, etc., both crystallized and massive; at Conway, Mass., in a vein of quartz; at Plainfield and West Stockbridge, Mass.; at Winchester, N. H.; at Salisbury and Kent, Conn., forming velvet-like coatings on limonite; Crimera and Old Dominion mines, Augusta Co., and elsewhere in Virginia; Pope, Pulaski, Montgomery Cos., Arkansas. In California, on Red island, bay of San Francisco. In New Brunswick, 7 m. fr. Bathurst, in fine cryst.; in Shepody Mtn. and elsewhere; near Upham in King's Co. In Nova Scotia, at Teny cape, cryst. and massive; also at Walton, abundant; near Kentville; Pictou; Amherst; Musquodobit.

The name is from πῦρ, *fire*, and λούειν, *to wash*, because used to discharge the brown and green (FeO) tints of glass; and for the same reason it is whimsically entitled by the French *le savon de verriers*.

WAD: Bog manganese, asbolite, lampadite.

255. **TURGITE.** Hematite pt. Red Ocher pt. Turgit *Herm.*, Bull. Soc. Nat. Moscow, **1**, 252, 1845. Hydrohæmatit *Breith.*, Handb., 846, 1847. Turjit.

Compact fibrous and divergent, to massive; often botryoidal and stalactitic like limonite. Also earthy, as red ocher.

H. = 5–6. G. = 4·29–4·49, Hof, Breith.; 4·681, Horhausen, Bergemann; 4·14, Salisbury, Brush. Luster submetallic and somewhat satin-like in the direction of the fibrous structure; also dull, earthy. Color reddish black to dark red, bright red when earthy; botryoidal surface often lustrous, like much limonite. Streak red. Opaque.

**Comp.**—$Fe_4H_2O_7$ or $2Fe_2O_3.H_2O$ = Oxygen 28·5, iron 66·2, water 5·3 = 100, or Iron sesquioxide 94·7, water 5·3 = 100.

For analyses, see 5th Ed., p. 168. Heddle (Min. Mag., **5**, 3, 1882) has analyzed cubic crystals, pseudomorphs after pyrite, from the clay slate of the island of Kerrera, Argyllshire, which had the composition of turgite, with G. = 3·534. Turgite is sometimes regarded as an intermediate stage in the alteration of limonite to hematite by loss of water.

**Pyr., etc.**—Heated in a closed tube, flies to pieces in a remarkable manner, and in this is distinct from hematite and limonite; yields water. Otherwise like hematite.

**Obs.**—A common ore of iron, often taken for limonite, with which it is frequently associated, and which it resembles, except in its superior hardness, streak, and decrepitation. It also looks very much like fibrous hematite. Hermann's mineral was from the Turginsk copper mine near Bogoslovsk, in the Ural, and from the Kolyvan district, in the Altai; that of Breithaupt, from near Hof in Bavaria, and Siegen in Prussia; found also with limonite at Düsseldorf in Prussia; at the Louisa mine, Horhausen. In the United States it occurs abundantly, in large botryoidal masses, at the limonite ore bed of Salisbury, Ct. (Brush), usually constituting the exterior layer of the limonite, sometimes an inch or more thick. The line of demarcation between it and the limonite is very distinct, and separation along it is often easy.

**256. DIASPORE.** Diaspore *Haüy*, Tr., 4, 1801. Blättricher Hydrargillit *Hausm.*, Handb., 442, 1813. Empholite *Igelström*, Bull. Soc. Min., 6, 40, 1883; *A. E. Nordenskiöld*, G. För. Förh., 9, 30, 1887.

Orthorhombic. Axes: $\breve{a} : \bar{b} : \dot{c} = 0{\cdot}93722 : 1 : 0{\cdot}60387$ Koksharov[1].

$100 \wedge 110 = 43° 8' 38''$, $001 \wedge 101 = 32° 47' 40''$, $001 \wedge 011 = 31° 7' 35''$.

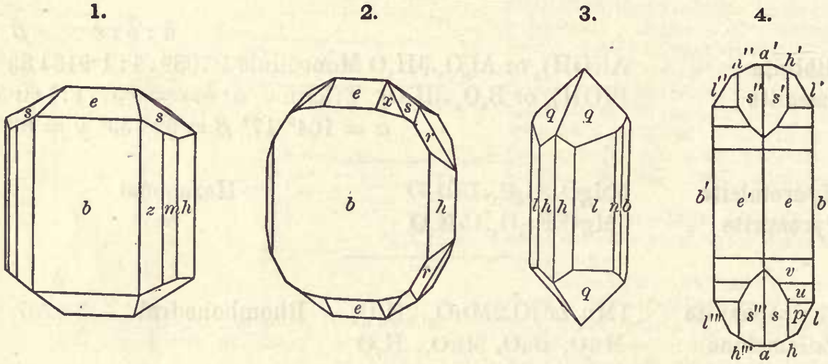

Figs. 1, 2, Ural, Kk. 3, Newlin, Penn. 4, Chester, Mass.

Crystals prismatic; usually thin, flattened ∥ *b*; sometimes acicular; faces often rounded, in prismatic zone vertically striated, also in zone *a e*, ∥ edge *p*/*e*. Also foliated massive and in thin scales; sometimes stalactitic.

Cleavage: *b* eminent; *h* less perfect. Fracture conchoidal, very brittle. H. = 6·5–7. G. = 3·3–3·5; 3·432 Haüy; 3·452 Dufr.; 3·30–3·34, fr. Schemnitz. Luster brilliant; pearly on cleavage-face, elsewhere vitreous. Color whitish, grayish white, greenish gray, hair-brown, yellowish, to colorless; sometimes violet-blue in one direction, reddish plum-blue in another, and pale asparagus-green in a third (cf. Haid., l. c.). Transparent to subtranslucent. Optically +. Double refraction strong. Ax. pl. ∥ *b*. Bx ⊥ *a*. Dispersion $\rho < v$, feeble. Axial angles, Dx.[6]:

$2H_{a.r} = 103° 34'$ $\beta_r = 1{\cdot}719$ $\therefore\ 2V_r = 84° 8'$
$2H_{a.y} = 103° 53'$ $\beta_y = 1{\cdot}722$ $\therefore\ 2V_y = 84° 20'$
$2H_{a.bl} = 104° 38'$ $\beta_{bl} = 1{\cdot}729$ $\therefore\ 2V_{bl} = 85° 8'$
$2H_{o.r} = 121° 59'$ $2H_{o.y} = 121° 32'$ $2H_{o.bl} = 120° 48'$

**Comp.**—AlO(OH) or $Al_2O_3.H_2O$ = Alumina 85·0, water 15·0 = 100.

Some varieties yield a little $P_2O_5$ (Hermann, Shepard), probably from impurity. Analyses, see 5th Ed., p. 169.

**Pyr., etc.**—In the closed tube decrepitates strongly, separating into white pearly scales, and at a high temperature yields water. The variety from Schemnitz does not decrepitate. Infusible; with cobalt solution gives a deep blue color. Some varieties react for iron with the fluxes. Not attacked by acids, but after ignition soluble in sulphuric acid.

**Obs.**—Commonly found with corundum or emery in dolomite, chlorite schist, and other crystalline rocks, in nests, or as implanted crystals on corundum and other minerals. Occurs near Kossoibrod, district of Ekaterinburg in the Ural, in granular limestone with emery; at Schemnitz, Hungary, in veins between dolomite and limestone; in a gneissoid rock near Bournac in the Haute-Loire; at Broddbo near Falun; at the Hörrsjöberg, Wermland, Sweden (*empholite*) embedded in pyrophyllite and damourite with tourmaline, rutile, and cyanite; sparingly in the nephelite-syenite veins of southern Norway, sometimes as an inclusion in some secondary minerals, as the "spreustein" (Scheerer, cf. Bgr., Zs. Kr., **16**, 50, 1890); with corundum in dolomite at Campolongo, near Dazio Grande, in the canton of Tessin in Switzerland; Greiner in the Zillerthal; at Gumuch-dagh and Manser, Asia Minor, and the Grecian islands Naxos, Samos, and Nicaria, with emery, as detected by J. L. Smith.

In the U. S. with topaz and margarodite at Trumbull, Ct., but rare; with corundum and margarite at Newlin, near Unionville, Chester Co., Pa.; at the emery mines of Chester, Mass., in large plates and crystals; in cavities in massive corundum at the Culsagee mine, near Franklin, Macon Co., N. Carolina.

Named by Haüy from *διασπείρειν, to scatter*, alluding to the usual decrepitation before the blowpipe. Le Lièvre, as Haüy states, first made known the species, having found it at a mineral-dealer's in Paris, and given it to Vauquelin for analysis. Its original locality is supposed to have been the Ural.

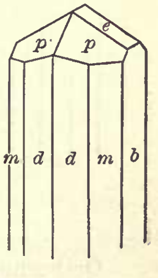
In prisms vertically striated, and often flattened into scales or tables ∥ *b*. Also fibrous; foliated or in scales; massive, reniform and stalactitic, with concentric and radiated structure.

Cleavage: *b* very perfect. Fracture uneven. Brittle. H. = 5–5·5. G. = 4·0–4·4; 4·37, cryst., Lostwithiel, Yorke. Luster imperfect adamantine. Color yellowish, reddish, and blackish brown. Often blood-red by transmitted light. Streak brownish yellow to ocher-yellow. Optically +(?). Ax. pl. ∥ *c*. Bx ⊥ *b*. Dispersion strong, $\rho < v$; for red nearly uniaxial; for green and blue, 2E = 50° approx.; cf. Palla, l. c.



**Var.**—1. In thin scale-like or tabular crystals, usually attached by one edge. Such is the original *Göthite* (*Pyrrhosiderite* or *Rubinglimmer*) of Siegen.

2. In acicular or capillary (not flexible) crystals, or slender prisms, often radiately grouped: the *Needle-Ironstone* (*Nadeleisenstein*). It passes into a variety with a velvety surface: the *Przibramite* (*Sammetblende*) of Přibram is of this kind.

*Onegite* is acicular göthite penetrating quartz, like rutile, from an island in L. Onega, Russia, where it was found in loose stones, in 1800, by Mr. Armstrong, an Englishman. It has also been called *Fullonite,* after Mr. Fullon, a brother-in-law of Mr. A., who also possessed specimens.

3. Columnar or fibrous.

4. Scaly-fibrous, or feathery columnar, the lines consisting of more or less distinct scales, somewhat like plumose mica: the *Lepidocrocite* (fr. λεπίς, *scale*, and κροκίς, *fiber*).

5. Also compact massive, with a flat conchoidal fracture, liver-brown to blackish brown and rust-brown color; sometimes reniform or stalactitic with radiated structure.

6. Disseminated microscopic crystals of göthite are one source of the frequent *aventurine* and opalescent character of specimens of different feldspars, and of some other species.

**Comp.**—FeO(OH) or $Fe_2O_3.H_2O$ = Oxygen 27·0, iron 62·9, water 10·1 = 100, or Iron sesquioxide 89·9, water 10·1 = 100.

Analyses, see 5th Ed., p. 170.

**Pyr., etc.**—In the closed tube gives off water and is converted into red iron sesquioxide. With the fluxes like hematite; most varieties give a manganese reaction, and some, treated in the forceps in O.F., after moistening in sulphuric acid, impart a bluish green color to the flame (phosphoric acid). Soluble in hydrochloric acid.

**Obs.**—Found with the other oxides of iron, especially hematite or limonite. Occurs at Eiserfeld near Siegen, in Nassau, in lamelliform and foliated crystallizations of a hyacinth-red color, with limonite; at Zwickau in Saxony; Oberkirchen in Westerwald, etc., near Clifton in Gloucestershire, near Bristol, England; in Cornwall, near Botallack and Lostwithiel, some of the crystals 1½ to 2 in. long and ⅝ in. across; in Somersetshire, at the Providence iron mines.

In the U. States, at the Jackson Iron mine, Negaunee, near Marquette, L. Superior, in lamelliform crystals; also in beautiful stalactitic forms with velvety surface and delicate radiated structure, often encrusting hematite; in Conn., at Salisbury; in Penn., near Easton, the var. lepidocrocite with limonite; with calcite in clay-ironstone concretions, Adair county, Mo.; in the Pike's Peak region, Colorado; in California, at Burns Creek, Mariposa Co., in quartz; in Oregon, 16 m. from Portland.

Named *Göthite* (Goethite) after the poet-philosopher Goethe (1749–1832); and *Pyrrhosiderite* from πυῤῥος, *fire-red*, and σίδηρος, *iron*. The name *Onegite* has priority, but it was given without a proper description, and for 25 years the nature of the mineral was unknown.

**Artif.**—By submitting solutions of $FeCl_3$ (30 to 85 pts. in 100) to the action of heat in closed tubes, Rousseau has obtained acicular crystals having the composition of göthite and like it orthorhombic, but, according to Fouqué, differing from it in optical characters. It does not seem certain, however, that there is any essential difference. C. R., **110**, 1032, 1890.

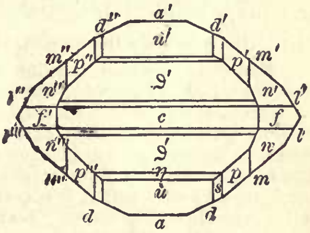
Twins: tw. pl. *e*, both contact- and cruciform-twins; often repeated and with comp.-face either parallel or inclined, analogous to rutile. Crystals long prismatic and terminated (1) by *c*, or (2) by zone of macropyramids *ρ*, *s*, *p*, etc.; planes in this zone striated parallel to their mutual intersections. Also short prismatic (3) terminated by *c* and numerous macrodomes; or (4) highly modified with macropyramids predominating; the last two types generally as twins. The prismatic faces deeply striated vertically. Crystals often grouped in bundles. Also columnar; seldom granular; stalactitic.

Cleavage: *b* very perfect; *m* perfect. Fracture uneven. Brittle. H. = 4. G. = 4·2–4·4; 4·315 cryst., Negaunee, Pfd. Luster submetallic. Color dark steel-gray to iron-black. Streak reddish brown, sometimes nearly black. Opaque; minute splinters, sometimes brown by transmitted light.

5.



5, Ilefeld, after Groth.

**Comp.**—$MnO(OH)$ or $Mn_2O_3.H_2O$ = Oxygen 27·3, manganese 62·4, water 10·3 = 100, or Manganese sesquioxide 89·7, water 10·3 = 100.

**Anal.**—Blomstrand, G. För. Förh., 2, 183, 1874. Also 5th Ed., p. 171.

Långban $Mn_2O_3$ 88·51 $Fe_2O_3$ 0·23 MgO 1·51 CaO 0·62 $H_2O$ 9·83 = 100·70

**Pyr., etc.**—In the closed tube yields water; otherwise like braunite, p. 232.

**Obs.**—Occurs in veins traversing porphyry, associated with calcite and barite, at Ilefeld in the Harz; Ilmenau and Oehrenstock in Thuringia; Undenaes and Långban in Sweden; Christiansand in Norway; Cornwall, at various places, occurring crystallized at Botallack mine, St. Just; Callington and at the Royal iron mines; also in Cumberland, Devonshire, Somerset; Aberdeenshire, Scotland; near Ross and elsewhere in Ireland.

In the L. Superior mining region at the Jackson mine, Negaunee, Michigan. Devil's Head, Douglas Co., Colorado. In Nova Scotia, at Cheverie, Hants Co., and Walton; also 10 m. W. of Walton, where it forms a bed of conglomerate, along with quartz pebbles. In New Brunswick, at Shepody mountain, Albert Co.; Tattagouche R., Gloucester Co.; Upham, King's Co.; and Dalhousie, Restigouche Co.

*Newkirkite* of Thomson, from Neukirchen in Alsace, according to Lettsom, is nothing but manganite.

Named acerdèse by Beudant from ἀκερδής, *unprofitable*, because of little value for bleaching purposes (cf. pyrolusite).

**Alt.**—By loss of water changes to pyrolusite, hausmannite, or braunite; pseudomorphs of pyrolusite (see p. 244) are very common. Cf. Breith., Pogg., **61**, 187, 1844.

**Ref.**—[1] Ed. J. Sc., **4**, 41, 1826, or Pogg., **7**, 225, 1826; Groth obtained similar results, also the author for L. Superior crystals. Hemihedrism has been suggested (Haid.) but seems improbable; cf. Köchlin, Min. Mitth., **9**, 24, 1887; Busz mentions crystals from Grettenich, Saarbrücken, with *n* (121) hemihedrally developed, Zs. Kr., **15**, 624, 1889. [2] See Groth, Min.-Samml., Strassburg, 79, 1878, also some other doubtful forms. Brauns adds (17·0·20), Jb. Min., **1**, 252, 1886; also Köchlin on pseudomorphous crystals Σ (10·5·1), l. c. [3] Groth, l. c.

Raseneisenstein (incl. Morasterz, Sumpferz, Wiesenerz) *Wern.*, Bergm. J., 383, 1789. Marsh Ore, Bog Ore, Meadow Ore pt., *Kirwan*, *Jameson*, etc. Limonit (= Raseneisenstein or Bog Ore) *Hausm.*, Handb., 283, 1813 [not Limonite of *Beud.*, wh. incl. *all* hydrous oxides of iron]. Limnit *Glock.*, Syn., 62, 1847.

Not crystallized. Usually in stalactitic and botryoidal or mammillary forms, having a fibrous or subfibrous structure; also concretionary, massive; and occasionally earthy.

H. = 5–5·5. G. = 3·6–4·0. Luster silky, often submetallic; sometimes dull and earthy. Color of surface of fracture various shades of brown, commonly dark, and none bright; sometimes with a nearly black varnish-like exterior; when earthy, brownish yellow, ocher-yellow. Streak yellowish brown. Opaque.

**Var.**—(1) *Compact.* Submetallic to silky in luster; often stalactitic, botryoidal, etc. (incl. brauner Glaskopf *Germ.*) (2) *Ocherous* or earthy, brownish yellow to ocher-yellow, often impure from the presence of clay, sand, etc. (3) *Bog ore.* The ore from marshy places, generally loose or porous in texture, often petrifying leaves, wood, nuts, etc. (4) *Brown clay-ironstone,* in compact masses, often in concretionary nodules (including Adlerstein, Klappenstein *Germ.*), having a brownish yellow streak, and thus distinguishable from the clay-ironstone of the species hematite and siderite; it is sometimes (*a*) *pisolitic,* or an aggregation of concretions of the size of small peas (Bohnerz *Germ.; bean ore*); or (*b*) *oolitic.*

Part of the stalactitic iron ore, brown or yellow ocher, bog ore, and clay-ironstone contains more water than true limonite, and hence belongs to the species *xanthosiderite* (or *limnite*).

*Kaliphite* of Ivanov is a mixture of limonite, manganese oxide, silicate of zinc and lime, from Hungary.

**Comp.**—$2Fe_2O_3.3H_2O$ = Oxygen 25·7, iron 59·8, water 14·5 = 100, or Iron sesquioxide 85·5, water 14·5 = 100. In the bog ores and ochers, sand, clay, phosphates, oxides of manganese, and humic or other acids of organic origin are very common impurities.

Analyses, see 5th Ed., p. 172. Analyses are chiefly interesting from the technical side as showing the amount of impurity ($SiO_2$, $P_2O_5$, etc.) present.

**Pyr., etc.**—Like göthite. Some varieties leave a siliceous skeleton in the salt of phosphorus bead, and a siliceous residue when dissolved in acids.

**Obs.**—In all cases a result of the alteration of other ores, or minerals containing iron, through exposure to moisture, air, and carbonic or organic acids; derived largely from the change of pyrite, magnetite, siderite, ferriferous dolomite, etc.; also various species (as mica, pyroxene, hornblende, etc.), which contain iron in the ferrous state (FeO). It consequently occupies, as a bog ore, marshy places, into which it has been borne by streamlets from the hills around; also found at the bottom of lakes as in Sweden (Sjömalm *Swed.*, Seeerz *Germ.*); and in the more compact form it occurs in stalactites as well as in tuberose and other concretionary forms, frequently making beds in the rocks which contain the minerals that have been altered into it. In moist places where a sluggish streamlet flows into a marsh or pool, a rust-yellow or brownish yellow deposit often covers the bottom, and an iridescent film the surface of the water: the deposit is a growing bed of bog ore. The iron is transported in solution as ferrous carbonate in carbonated waters, a sulphate, or as a salt of an organic acid. It is often associatedwith manganese ores. Limonite is a common ore in Bavaria, the Harz, Luxembourg, Scotland, Sweden, etc.

Abundant in the United States. A few localities only are here mentioned; reference may be made to the various geological reports for complete lists. Extensive beds exist at Salisbury and Kent, Conn., also in the neighboring towns of Beekman, Fishkill, Dover, and Amenia, N.

Y., and in a similar situation north; at Richmond, West Stockbridge and elsewhere in Berkshire Co., Mass.; in Vermont, at Bennington, Monkton, Pittsford, Putney, and Ripton; in Pennsylvania widely distributed especially in the south-eastern part of the state; also in Tennessee, Alabama, Ohio, etc.

Named *Limonite* from λειμών, *meadow.* Ullmann's name, *Stilpnosiderite,* from στιλπνός, *shining,* has priority; but the ore is characteristically not a shining ore, although sometimes with a lustrous, varnish-like exterior. The name *limonite* was first appropriated especially to the *bog* ores by Hausmann in 1813. But most bog ores are of the above species, and Beudant, recognizing this, in 1832 used limonite for the *bog* as well as other limonite.

**Alt.**—By deoxidation through organic matter, if carbonic acid is present, may form siderite. By losing water becomes hematite, which occurs as pseudomorphs after limonite. This species also forms numerous pseudomorphs after other species.

---

**260. XANTHOSIDERITE.** Gelbeisenstein *Hausm.*, Handb., 279, 1813. Xanthosiderit *E. E. Schmid,* Pogg., **84**, 495, 1851. Yellow Ocher pt. Bog Ore pt.

In fine needles or fibers, stellate and concentric. Also as an ocher.

H. = 2·5, in needles. Luster silky or greasy; pitch-like; also earthy. Color in needles golden yellowish, brown to brownish red; as an ocher, yellow of different shades, more or less brown, sometimes reddish. Streak ocher-yellow.

**Comp.**—$Fe_2O_3.2H_2O$ = Oxygen 24·5, iron 57·1, water 18·4 = 100, or Iron sesquioxide 81·6, water 18·4 = 100.

Analyses, see 5th Ed., p. 174.

**Pyr., etc.**—Like those of limonite.

**Obs.**—Associated with manganese ores at Ilmenau, in silky needles, etc.; as an ocher near Goslar, Bruchberg, Elbingerode in the Harz; as a pitchy ore at Kilbride, Wicklow Co., Ireland, along with limonite and psilomelane.

**Artif.**—This hydrate is formed when oxide of iron is precipitated from hot solutions of its salts; and, according to Gmelin, also from cold solutions.

LIMNITE *Dana,* Min., 178, 1868. Quellerz *Hermann,* J. pr. Ch., **27**, 53, 1842. Raseneisenerz, Sumpferz, Wiesenerz *Germ.* A hydrated iron oxide, for the most part bog ore, recent in origin and containing organic acids with quartz sand, phosphoric acid, etc. The composition $Fe(OH)_3$ or $Fe_2O_3.3H_2O$, has been attributed to it. Cf. Rg., Min. Ch., 187, 1865.

**261. BAUXITE.** Alumine hydratée de Beaux *Berthier,* Ann. Mines, **6**, 531, 1821. Beauxite *Dufr.*, Min. (**2**, 347), **3**, 799, 1847. Bauxite *Deville,* Ann. Ch. Phys., **61**, 309, 1861. Wocheinite *A. Flechner,* Zs. G. Ges., **18**, 181, 1866, Jb. G. Reichs., 1866. Cliachite *Adam,* Tabl. Min., 73, 1869.

In round concretionary disseminated grains. Also massive, oölitic; and earthy, clay-like.

G. = 2·55, fr. Wochein, v. Lill. Color whitish, grayish, to ocher-yellow, brown, and red.

**Var.**—1. In concretionary grains, or oölitic; *bauxite.* 2. Clay-like, *wocheinite;* the purer kind grayish, clay-like, containing very little iron oxide; also red from the iron oxide present.

**Comp.**—Essentially $Al_2O_3.2H_2O$ = Alumina 73·9, water 26·1 = 100; some analyses, however, give $Al_2O_3.H_2O$ like diaspore.

Iron sesquioxide is usually present, sometimes in large amount (up to 50 p. c. Henatsch), in part replacing alumina, in part only an impurity. Silica, phosphoric acid, carbonic acid, lime, magnesia are common impurities.

Analyses, see 5th Ed., pp. 174, 175; also Coquand, Bull. Soc. G. Fr., **28**, 98, 1871; Augé, ibid., **16**, 345, 1888; John, Vh. G. Reichs., 389, 1874; Lang, Ber. Ch. Ges., **17**, 2892, 1884; Henatsch, Inaug. Diss., Breslau, 1879. The analyses are interesting chiefly on the technical side, as showing the amount of impurity present; thus Henatsch gives 9 to 24 p. c. $SiO_2$, 0·8 to 2·5 p. c. $P_2O_5$, etc.

**Obs.**—From Baux (or Beaux), near Arles, France, disseminated in grains in compact limestone, and also oölitic; also at Revest, near Toulon, brown to dark red, and massive, regarded as an iron ore; at Allauch, Dept. of Var, France, massive, oölitic, with a base of like nature, cemented by some calcium carbonate, the most common variety; at Hügel, in the Commune of Baux, a hard and firm variety; at Calabre, massive; also in Nassau; in French Guiana. *Wocheinite* occurs in Carniola, between Feistritz and Lake Wochein, in a deposit 12 feet thick, the junction of the Trias and Jurassic formations, part of it red from iron sesquioxide. The purest bauxite is used for the manufacture of aluminium, and is called *aluminium ore.*

In the U. S., bauxite occurs in Saline and Pulaski Cos., Arkansas.

Augé, l. c., regards bauxite as a hydro-thermal deposit; he calls attention to the occurrence of hydrated alumina in the Yellowstone region.

## Brucite Group. R(OH)$_2$. Rhombohedral.

**262. BRUCITE.** Native Magnesia (fr. N. Jersey) *A. Bruce*, Bruce's Min. J., **1**, 26, 1814 (with anal.). Hydrate of Magnesia *A. Aikin*, Min., 236, 1815, *Cleaveland*, Min., 429, 1822. *F. 1.

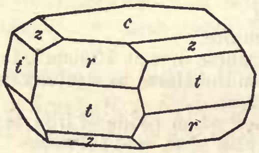
2.



3.

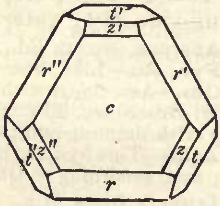


Fig. 1, Low's Mine, Texas, Penn. Figs. 2, 3, Wood's Mine, Texas.

Crystals usually broad tabular. Also commonly foliated massive; fibrous, fibers separable and elastic.

H. = 2·5. G. = 2·38–2·4; 2·388 Ural, Lösch. Cleavage: *c* eminent. Folia separable and flexible, nearly as in gypsum. Sectile. Luster ∥ *c* pearly, elsewhere waxy to vitreous. Color white, inclining to gray, blue or green. Transparent to translucent. Optically +. Indices: $\omega_r$ = 1·559, $\epsilon_r$ = 1·5795 Bauer[3]. Pyroelectric, on cooling the extremities of $\dot{c}$ −, the edges +, Hankel[4].

**Comp., Var.**—Magnesium hydrate, Mg(OH)$_2$ or MgO.H$_2$O = Magnesia 69·0, water 31·0 = 100. Iron and manganese protoxide are sometimes present.

**Var.**—1. *Ordinary.* In plates, white to pale greenish in color; strong pearly luster on the cleavage surface.

2. *Nemalite.* A fibrous variety containing 4 to 5 p. c. iron protoxide, with G. = 2·44 Nuttall.

3. *Manganbrucite.* Granular, massive. Color honey-yellow to brownish red; perhaps originally colorless; contains manganese in considerable amount, anal. 7; cf. also anal. 3.

**Anal.**—1, E. F. Smith, Am. Ch. J., **5**, 281, 1883. 2, 3, F. A. Genth, Am. Phil. Soc., **23**, 40, 1885. 4, Smith, l. c. 5, Rosenblad, G. För. Förh., **7**, 733, 1885. 6, T. Blyth, Mallet, Min. India, 161, 1887. 7, Igelström, l. c.; small amounts of SiO$_2$ and CaCO$_3$ have been deducted. Also 5th Ed., p. 176.

| | | MgO | FeO | MnO | H$_2$O | |
|---|---|---|---|---|---|---|
| 1. Fritz Island | | 66·78 | 0·44[a] | — | 32·52 | = 99·74 |
| 2. " | | 67·64 | 0·82[a] | 0·63 | 30·92 | = 100·01 |
| 3. " | G. = 2·382 | 65·38 | 0·30[a] | 4·04 | 29·70 | = 99·42 |
| 4. Sinking Spring | | 66·19 | 1·24[a] | — | 31·05 | CaO 1·68 = 100·16 |
| 5. Ural | G. = 2·388 | 69·02 | 0·61 | — | 30·23 | CO$_2$ 0·09 = 99·95 |
| 6. Afghánistán, *fibrous* | | 60·95 | 11·14 | — | 29·32 | insol. 0·38 = 101·79 |
| 7. Jakobsberg, *manganbrucite* | | 57·81 | — | 14·16 | 28·00 | = 99·97 |

[a] Fe$_2$O$_3$.

**Pyr., etc.**—In the closed tube gives off water, becoming opaque and friable, sometimes turning gray to brown; the manganesian variety becomes dark brown. B.B. infusible, glows with a bright light, and the ignited mineral reacts alkaline to test-paper. With cobalt solution gives the pale pink color of magnesia. The pure mineral is soluble in acids without effervescence.

**Obs.**—Accompanies other magnesian minerals in serpentine, and has also been found in limestone. Occurs in considerable veins traversing serpentine, at Swinaness in Unst, one of the Shetland Isles, where it is sometimes found in crystals; at Pyshminsk in the Urals; at Goujot in France; at the iron mine of Cogne, valley of Aosta, Italy; near Filipstadt in Wermland, in Sweden, in roundish masses in limestone.

At Hoboken, N. J., in serpentine; at the Tilly Foster iron mine, Brewster, N. Y., well crystallized, also pseudomorph after dolomite and altered to serpentine; in Richmond Co., N. Y.; on the peninsula east of New Rochelle, Westchester Co., N. Y.; at Wood's mine, Texas, Pa., in large plates or masses, and often crystallizations several inches across; at Low's mine, with hydromagnesite; at Fritz Island, near Reading, and near Sinking Spring, Spring Township.

*Nemalite*, the fibrous variety, occurs at Hoboken, and Xettes in the Vosges. *Manganbrucite* occurs with hausmannite and other manganese minerals in the granular limestone of Jakobsberg, Nordmark, Sweden.

Named after A. Bruce (1777–1818), an early American mineralogist, who first described the species.

**Alt.**—Becomes white, pulverulent, and carbonated on exposure, and also crystallized, constituting then the mineral hydromagnesite; the latter is sometimes in pseudomorphous crystals after brucite. Also altered to serpentine (see above).

**Artif.**—Has been noticed in crystalline plates as a deposit in a steam-boiler (Luedecke, Zs. Kr., **7**, 502, 1883). Also obtained by de Schulten from a solution of magnesium chloride precipitated by an excess of caustic potash and heated to 200°; the crystals of brucite separate out on cooling.

**Ref.**—[1] Texas, Penn., Min. Not., **4**, 40, 1861. [2] Cf. Hbg.; also Mlr., Min., 269, 1852, Rose, Zs. G. Ges., **12**, 178, 1860; Schrauf, Atlas, Tf. XL; Erem., Vh. Min. Ges., **16**, 310, 1881. [3] Ber. Ak. Berlin, 958, 1881. [4] Wied. Ann., **6**, 53, 1879. On the percussion-figure, Mgg., Jb. Min., **1**, 57, 1884.

EISENBRUCIT *Sandberger*, Jb. Min., **2**, 288, 1880. A product of partially decomposed brucite from Siebenlehn near Freiberg. An anal. gave Petersen: MgO 38·92, FeO 18·73, $CO_2$ 7·38, $H_2O$ 30·46, $SiO_2$ 4·15, $Al_2O_3$,CaO *tr.* = 99·64. After deducting the $SiO_2$ as quartz, and 24·49 p. c. hydromagnesite believed to be present, the result is: MgO 39·89, FeO 24·92, $H_2O$ 35·19 = 100.

## 263. PYROCHROITE.

Pyrochroit *L. J. Igelström*, Pogg., **122**, 181, 1864, Öfv. Ak. Stockh., **21**, 205, 1864.

Rhombohedral. Axis $\dot{c} = 1·3999$; $cr = {}^*58° 15\frac{1}{2}'$, $rr' = 94° 52'$ Flink[1]. In hexagonal tabular crystals. Usually foliated, like brucite.

H. = 2·5. G. = 3·258 artif., de Schulten. Luster pearly. Color white; but changing on exposure to bronze, and then to black. In thin pieces transparent, and having a flesh-red color by transmitted candle-light. Optically uniaxial, negative.

**Comp.**—Manganese hydrate, $Mn(OH)_2$ or $MnO.H_2O$ = Manganese protoxide 79·7, water 20·3 = 100.

**Anal.**—1, 2, L. Stahre, G. För. Förh., **4**, 163, 1878.

| | MnO | FeO | CaO | MgO | $H_2O$ | $CO_2$ |
|---|---|---|---|---|---|---|
| 1. *Cryst.* | 76·56 | 0·47 | 0·29 | 2·39 | 18·57 | 1·99 = 100·27 |
| 2. *Massive* | 77·67 | 0·20 | *tr.* | 1·33 | 20·00 | 1·07 = 100·27 |

**Pyr., etc.**—In the closed tube a small piece becomes at surface verdigris-green, then dirty green, and finally brownish black. Yields water. B.B. reactions for manganese. In hydrochloric acid forms easily a clear colorless solution.

**Obs.**—Occurs in veins 1 to 2 lines broad in magnetite at Pajsberg, Filipstadt, Sweden; at the Moss mine at Nordmark in Wermland; at the Sjö mine, Grythyttan, Örebro. It is commonly associated with hausmannite. Identified by Roepper at Franklin Furnace, N. J.

Named from πῦρ, *fire*, χρόα, *color*, because of the change of color upon ignition.

**Artif.**—Obtained by de Schulten in hexagonal crystals, Bull. Soc. Min., **10**, 326, 1887.

**Ref.**—[1] Flink, Nordmark, Ak. Handl. Stockh., Bihang, **12** (2), No. 2, 12, 1886.

Kenngott refers here (Jb. Min., 440, 1866) a mineral which Wiser had announced as a hydrous carbonate of manganese, and which Haidinger (Handb., 493, 1845) named *Wiserite*. It is described as yellowish white to gray in color, pearly to silky in luster, fibrous in structure, and as coming from Gonzen near Sarganz, the Canton of St. Gall, in Switzerland, where it is found in seams in a granulitic hausmannite, with rhodochrosite.

**264. GIBBSITE.** Wavellite (fr. Richmond) *C. Dewey*, Am. J. Sc., **2**, 249, 1820; = Water and Alumina, *id.*, ib., **3**, 239, 1821. Gibbsite *J. Torrey*, N. Y. Med. Phys. J., **1**, No. 1, 68, April, 1822. Hydrargillite, Gibbsite of Torrey, *Cleavel.*, 224, 782, 1822. Hydrargillite (fr. Ural) *G. Rose*, Pogg., **48**, 564, 1839.

Monoclinic. Axes $\grave{a} : \bar{b} : \grave{c} = 1·70890 : 1 : 1·91843$; $\beta = 85° \ 29\frac{1}{6}'$ = 001 ∧ 100 Brögger[1].

100 ∧ 110 = 59° 35¼′, 001 ∧ $\bar{1}$01 = *50° 50′, 001 ∧ 011 = 62° 23¾′.

**Forms:**
$a$ (100, $i$-$\bar{i}$)
$b$ (010, $i$-$\grave{i}$)
$c$ (001, $O$)
$t$ (920, $i$-$\frac{9}{2}$)
$l$ (410, $i$-$\bar{4}$)
$k$ (310, $i$-$\bar{3}$)?
$\nu$ (520, $i$-$\frac{5}{2}$)?
$\mu$ (210, $i$-$\bar{2}$)
$n$ (870, $i$-$\frac{8}{7}$)
$m$ (110, $I$)
$d$ ($\bar{1}$01, 1-$\bar{i}$)
$s$ ($\bar{3}$12, $\frac{3}{2}$-$\bar{3}$)
$u$ ($\bar{6}$23, 2-$\bar{3}$)
$o$ ($\bar{2}$11, 2-$\bar{2}$)?

Angles: $tt'''$ = 41° 28′, $ll'''$ = 46° 8′, $\mu\mu'''$ = 80° 51′ $nn'''$ = 112° 17′ $mm'''$ = *119 10½′, $cm$ = *87° 43′.

Twins: tw. pl. (1) $m$ with $cc$ = − 4° 34′, rare. (2) $a$ with $cc$ = − 9° 2′, not common. (3) $c$, common, usually combined with one of the other laws. (4) tw. pl. ⊥ $c$ and intersecting $c$ in a line inclined 119° 49½′ to the edge $c/a$, and 0° 31½′ to the edge $c/m$; very common, the faces $c$ and $\underline{c}$ falling together, while the zone $ca$ of one crystal coincides with the zone $cm$ of the other; method of grouping very varied, in part analogous to the pericline twins of the triclinic feldspars. Also rare and somewhat uncertain, (5) tw. pl. ($\bar{3}$·1·54, $\frac{1}{18}$-$\bar{3}$?).

Crystals tabular ∥ $c$, the forms $c$ $a$ $m$ most common; hence hexagonal in aspect. Occasionally in lamello-radiate spheroidal concretions. Also stalactitic, or small mammillary and incrusting, with smooth surface, and often a faint fibrous structure within.

Cleavage: $c$ eminent. Tough. Percussion-figure[2] similar to that of mica, with rays normal to the hexagonal edges. H. = 2·5–3·5. G. = 2·3–2·4; 2·385, Richmond, B. Silliman, Jr.; 2·287, Ural, Hermann; 2·420, Norway, Bgr. Color white, grayish, greenish, or reddish white; also reddish yellow when impure. Luster of $c$ pearly; of other faces vitreous; of surface of stalactites faint. Translucent; sometimes transparent in crystals. A strong argillaceous odor when breathed on.

Optically +. For Uralian crystals (Dx.), ax. pl. usually ⊥ $b$, and inclined 41° 26′ to a normal to $c$ for red, dispersion strong $\rho > v$, horizontal inappreciable; increase of temperature causes a gradual change in the axial plane until at 56°·5 and above the ax. pl. becomes ∥ $b$, the angles increasing with $\rho > v$ up to 171° C.; in all cases the bisectrix lies in the plane of symmetry; at 26°·5 nearly uniaxial for blue. In another section, ax. pl. ∥ $b$ at ordinary temperature, and axes inclined respectively 50° 12′ and 35° 9½′ (red) to a normal to $c$. Brazilian crystals (Dx.) similar to those from the Ural. The Norwegian crystals (Bgr.) are sensibly uniaxial with Bx ∧ $\grave{c}$ = − 21°. Refractive indices:

$$\alpha = \beta = 1·53471 \qquad \gamma = 1·55769$$

**Var.**—1. In crystals; the original *Hydrargillite*. 2. Stalactitic; *gibbsite*.

**Comp.**—Aluminium hydrate, $Al(OH)_3$ or $Al_2O_3.3H_2O$ = Alumina 65·4, water 34·6 = 100.

Analyses, see 5th Ed., p. 177. Also Eustis, Brazil, Ch. News, **48**, 98, 1883; da Costa Sena, id., Bull. Soc. Min., **7**, 220, 1884; Jannettaz, French Guiana, ibid., **1**, 70, 1878.

**Pyr., etc.**—In the closed tube becomes white and opaque, and yields water. B.B. infusible, whitens, and does not impart a green color to the flame. With cobalt solution gives a deep blue color. Soluble in concentrated sulphuric acid.

**Obs.**—The crystallized gibbsite (hydrargillite) was discovered by Lissenko in the Shishimsk mountains near Zlatoust in the Ural; it occurs, according to Koksharov, in cavities in a schist containing much magnetite. The larger crystals were 1 to 2 inches long. Also in crystals filling cavities in natrolite on the small islands, Lille-Arö and Eikaholm, in the Langesundfiord, Norway. With corundum at Gumuch-dagh, Asia Minor. In French Guiana. Ouro Preto and Marianna, Minas Geraes, Brazil.

In the U. S. on corundum at Unionville, Pa.(?); in stalactitic form at Richmond, Mass., in a bed of limonite; also at Lenox, Mass.; at the Clove Mine, Union Vale, Dutchess Co., N. Y., on limonite; in Orange Co., N. Y.

Named after Col. George Gibbs, the original owner (after extensive foreign travel) of the large Gibbs cabinet acquired by Yale College early in the century. Cleaveland calls the Richmond mineral *hydrargillite* on p. 224 of his mineralogy, but on p. 782 adopts Torrey's name *gibbsite*.

**Ref.**—[1] Norway, Zs. Kr., **16**, 16, 1890. Earlier regarded as rhombohedral, Kk., Min. Russl., **4**, 88, 1862, but proved by Dx. to be monoclinic, ibid., p. 398, and N. R., 138, 1867. It is shown by Bgr. that the orthopinacoid of Dx. is in fact the prism *m*. [2] Jb. Min., **1**, 56, 1884.

RICHMONDITE. The substance labelled gibbsite from Richmond, Mass., in which Hermann states he found 37 p. c. $P_2O_5$ (see his analysis under gibbsite, 5th Ed., p. 178), has been named *Richmondite* by Kenngott (Vierteljahrschr. nat. Ges. Zürich, **11**, 225).

ZIRLITE *Pichler*, Jb. Min., 57, 1871, 51, 1875. An amorphous aluminium hydrate resembling allophane from near Zirl, Tyrol, also from Nassereit; it occurs in yellowish white incrustations in a sandy marl. Easily soluble in acids.

**265. SASSOLITE.** Sale sedativo naturale *U. F. Hoefer*, Memoria, Firenze, 1778; *Mascagni*, Mem. Soc. Ital., 8, 487. Native Sedative Salt. Acidum boracis, *vulgo* Sal sedativum, *Bergm.*, Sciagr., 1782. Native Boracic Acid *Kirw.*, 1796. Sassolin *Karst.*, Tab., 40, 75, 1800. Acide boracique *Fr.* Boric Acid.

Triclinic. Axes: $\breve{a} : \bar{b} : \acute{c} = 0{\cdot}57711 : 1 : 0{\cdot}52824$; $\alpha = 104° 17\frac{1}{3}'$; $\beta = 92° 33\frac{1}{3}'$; $\gamma = 89° 41\frac{5}{6}'$ Miller[1].

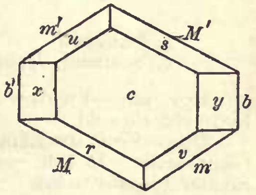
$100 \wedge 010 = 89° 39\frac{2}{3}'$, $001 \wedge 100 = 87° 26\frac{1}{3}'$, $001 \wedge 010 = 75° 42\frac{1}{2}'$.

**Forms**[1]: *m* (110, *I'*) *y* (011, 1-ĭ') *v* (111, 1') *u* ($\bar{1}\bar{1}$1, 1,)
*b* (010, *i*-ĭ) *M* (1$\bar{1}$0, '*I*) *x* (0$\bar{1}$1, '1-ĭ) *s* ($\bar{1}$11, ,1) *r* (1$\bar{1}$1, '1)
*c* (001, *O*)

If the axes $\breve{a}$ and $\bar{b}$ are interchanged, and at the same time the axis $\acute{c}$ doubled, the axial ratio becomes: $\bar{a} : b : c = 1{\cdot}7328 : 1 : 1{\cdot}8306$, which brings it into correspondence with gibbsite (hydrargillite).

*bm* = *59° *cv* = 41° 6' *cr* = 48° 26' *b'r* = 78° 24'
*b'M* = 59° 30' *cm* = *80° 33' *cM* = *95° 3' *bs* = 59° $4\frac{1}{2}'$
*mM* = *61° 30' *cu* = 50° 53' *Mr* = *46° 37' *b'u* = 77° 26'
*cy* = 24° 21' *cs* = 43° 14' *bv* = 59° 51' *ys* = 36° 18'
*cx* = 36° 27'

Twins: tw. axis $\acute{c}$; $c\underline{c} = 29° 2'$ (Mlr.). Crystals tabular ∥ *c*, the plane angles of the basal plane nearly 120°. Usually small scales; sometimes grouped in stalactitic forms.



Cleavage: *c* very perfect. H. = 1. G. = 1·48. Luster pearly. Color white, except when tinged yellow by sulphur; sometimes gray. Feel smooth and unctuous. Taste acidulous, and slightly saline and bitter. Ax. pl. nearly coincident with axis $\bar{b}$ and ⊥ *c*. Bx ⊥ *c*. 2E = 8° Mlr. 2E = 10° to 12° and unchanged by heat (to 75° C.) Dx. Dispersion zero.

**Comp.**—Boric acid, $B(OH)_3$ or $B_2O_3.3H_2O$ = Boron trioxide 56·4, water 43·6 = 100.

**Pyr., etc.**—In the closed tube gives water. B.B. on platinum wire fuses to a clear glass and tinges the flame yellowish green. Some specimens react for sulphur or ammonia in the closed tube. Soluble in water and alcohol. Dissolves in 2·97 parts of water at 100° C., and 10·7 parts at 50° C.

**Obs.**—This long known compound, the *Sal sedativum Hombergii*, was first detected in nature by Hoefer in the waters of the Tuscan lagoons of Monte Rotondo and Castelnuovo, and afterward in the solid state at Sasso by Mascagni. The hot vapors of the lagoons consist largely of boric acid. To collect it the vapors are made to pass through water, which absorbs the boric acid; the waters are then evaporated by means of the steam from the springs. Have yielded seven to eight thousand pounds troy per day. These lagoons spread over a surface of about 30 miles; and in the distance, clouds of vapor are seen rising in large volumes among the mountains.

Exists also in other natural waters, as at Wiesbaden; Aachen; Krankenheil near Fölz; Clear Lake, in Lake Co., California; has been detected in the waters of the ocean.

Occurs also abundantly in the crater of Vulcano, one of the Lipari isles, forming a layer on sulphur, and about the fumaroles, where it was discovered by Dr. Holland in 1813.

**Ref.**—[1] Trans. Phil. Soc. Cambr., 3, 365, 1830, Pogg. Ann., **23**, 558, 1831, Min., p. 281. Kenngott made the artificial crystals monoclinic, Ber. Ak. Wien, **12**, 26, 1854. Cf. also Dx., Min., **2**, 1, 1874, and Haushofer, Zs. Kr., **9**, 77, 1884, who gives new measurements.

**266. HYDROTALCITE.** Hydrotalkit *Hochstetter*, J. pr. Ch., **27**, 376, 1842. Völknerite *Herm.*, J. pr. Ch., **40**, 11, 1847, **46**, 257, 1849.

Hexagonal. Also lamellar-massive, or foliated, and somewhat fibrous.

Cleavage: basal, eminent; lateral, distinct. H. = 2. G. = 2·04–2·09; 2·091 Rg. Color white. Luster pearly. Translucent, or in thin folia transparent. Feel greasy.

**Comp.**—Perhaps $Al(OH)_3.3Mg(OH)_2.3H_2O$ or $Al_2O_3.6MgO.15H_2O$ = Alumina 16·7, magnesia 39·2, water 44·1 = 100.

Analyses (Hermann, Rg., see 5th Ed., p. 179) show the presence of a carbonate in considerable amount (2·6 to 7·3 p. c. $CO_2$, Rg.). so that the true nature of the mineral is not above doubt.

**Pyr., etc.**—In the closed tube yields much water. B.B. infusible, but exfoliates somewhat, and gives out light. A pale rose-red with cobalt solution. With the fluxes intumesces and affords a clear colorless glass. The Snarum mineral reacts for iron.

**Obs.**—Occurs at the mines of Shishimsk, district of Zlatoust, Ural, implanted on schist (*völknerite*); at Snarum, Norway, in serpentine (*hydrotalcite*).

Named *hydrotalcite* in allusion to its resembling talc, but containing much more water; *völknerite*, after Captain Völkner.

HOUGHITE *Shepard*, Am. J. Sc., **12**, 210, 1851. A hydrotalcite derived from the alteration of spinel. From near Oxbow, and near Somerville in Rossie, St. Lawrence Co., New York. Color white; luster faint, pearly. The crystals are in all conditions, from the pure spinel to octahedrons with rounded edges and pitted or irregular surfaces, and it also occurs in flattened nodules. The surfaces are sometimes soft and altered, when the edges or angles have the hardness of spinel. Analysis, see S. W. Johnson, ibid., p. 361, or 5th Ed., p. 179. Associated with dolomite, spinel, phlogopite, graphite, and serpentine. Named for Franklin B. Hough of Somerville.

**267. PYROAURITE.** Pyroaurit *Igelström*, Öfv. Ak. Stockh., **22**, 608, 1865. Igelströmite *Heddle* Min. Mag., **2**, 107, 1878.

Hexagonal. In six-sided tables. Also with obscure fibrous structure.

Luster pearly. Color gold-like or silvery white. Subtranslucent.

**Comp.**—Perhaps $Fe(OH)_3.3Mg(OH)_2.3H_2O$ or $Fe_2O_3.6MgO.15H_2O$ = Iron sesquioxide 23·9, magnesia 35·8, water 40·3 = 100.

**Anal.**—1, Igelström, l. c. 2, Heddle, l. c.; also other analyses with some $CO_2$.

| | $Fe_2O_3$ | MgO | $H_2O$ | $CO_2$ | | |
|---|---|---|---|---|---|---|
| 1. Långban | 23·92 | 34·04 | 34·56 | 7·24 | = | 99·76 |
| 2. Scotland, *Igelströmite* | 23·63 | 36·85 | 40·02 | — | = | 100·50 |

**Pyr., etc.**—Yields water. B.B. infusible, turns brown and becomes magnetic. Soluble in hydrochloric acid.

**Obs.**—From the Långban iron mine in Wermland, Sweden, in gold-like submetallic scales (*pyroaurite*). In thin seams of a silvery white color in serpentine in the island Haaf-Grunay, Scotland (*igelströmite*).

**268. CHALCOPHANITE.** *G. E Moore*, Amer. Chemist, July, 1875.

Rhombohedral. Axis $\dot{c}$ = 3·5267; 0001 ∧ $10\bar{1}1$ = 76° $12\frac{1}{6}'$ Moore.

In druses of minute tabular crystals, with small rhombohedral faces. Angles: $rr'$ = 114° 30′, $rr'''$ = *65° 30′. Also in foliated aggregates; in stalactitic and plumose forms.

Cleavage: basal, perfect. Flexible in thin laminæ. H. = 2·5. G. = 3·907. Luster metallic, brilliant. Color bluish black to iron-black. Streak chocolate-brown, dull. Opaque.

**Comp.**—$(Mn,Zn)O.2MnO_2.2H_2O$ = Manganese dioxide 60·3, manganese protoxide 6·1, zinc protoxide 21·1, water 12·5 = 100; here MnO : ZnO = 1 : 3.

**Anal.**—1, 2, Moore: 1, cryst.; 2, stalactitic, deducting 1·27 p. c. limonite.

| | $MnO_2$ | MnO | ZnO | $Fe_2O_3$ | $H_2O$ | | |
|---|---|---|---|---|---|---|---|
| 1. | 59·94 | 6·58 | $21·70\frac{2}{2}$ | 0·25 | 11·58 | = | 100·05 |
| 2. | $\frac{2}{2}$ 61·57 | 4·41 | 20·80 | — | 12·66 | = | 99·44 |

**Pyr.**—In the closed tube gives off water and oxygen, exfoliates slowly, and changes to a golden bronze color. B.B. becomes yellowish bronze to copper-red in color, and fuses slightly on the edges. With borax a manganese bead; on charcoal with soda a zinc coating. Dissolves in hydrochloric acid with the evolution of chlorine.

**Obs.**—Occurs at the calamine deposits of Sterling Hill, near Ogdensburg, Sussex Co., N. J. It is a product of the decomposition of franklinite. Named from χαλκός, *brass*, and φαινέσθαι, *to appear*, in allusion to the change of color on ignition.

**269. PSILOMELANE.** Derb Brunsten pt. *Wall.*, Min., 268, 1747. Magnesia indurata pt. *Cronst.*, Min., 106, 1758. Schwarz Braunsteinerz pt. *Wern.*, Bergm. J., 386, 1789. Schwarzer Glaskopf *Germ.* Calvonigrit *Laspeyres*, J. pr. Ch., **13**, 226, 1876.

Massive and botryoidal; reniform; stalactitic.

H. = 5–6. G. = 3·7–4·7. Luster submetallic; dull. Streak brownish black, shining. Color iron-black, passing into dark steel-gray. Opaque.

**Comp.**—A hydrous manganese manganate in which part of the manganese is often replaced by barium or potassium, perhaps conforming to $H_4MnO_5$ (Laspeyres). The material analyzed is generally very impure, and the composition hence doubtful.

**Anal.**—1, 2, Laspeyres. J. pr. Ch., **13**, 1, 215, 1876. 3, 4, Langhans, Inaug. Diss., Jena, 1885. 5, 6, Gorgeu, Bull. Soc. Min., **13**, 21, 1890.

Also 5th Ed., p. 180; Rg., Min. Ch., 189–191, 1875; Heddle, Trans. R. Soc. Edinb., **30**, 427, 1882.

The psilomelane from Kalteborn, Siegen (anal. 2), is called *calvonigrite* by Laspeyres (l. c., p. 226).

**Pyr., etc.**—In the closed tube most varieties yield water, and all lose oxygen on ignition; with the fluxes reacts for manganese. Soluble in hydrochloric acid, with evolution of chlorine.

**Obs.**—This is a common ore of manganese. It is frequently in alternating layers with pyrolusite. It occurs in botryoidal and stalactitic shapes, in Devonshire and Cornwall; at Ilefeld in the Harz; also at Johanngeorgenstadt, Schneeberg, Ilmenau, Siegen, etc.; at Elgersburg and Oehrenstock, Thuringia, and Nadabula, Hungary. In the Orkneys.

It forms mammillary masses at Chittenden, Irasburg, and Brandon, Vt. In Independence Co., and elsewhere in Arkansas. With pyrolusite at Douglas, Hants Co., Nova Scotia.

Named from ψιλός, *smooth* or *naked*, and μέλας, *black*.

LITHIOPHORITE *Frenzel*, J. pr. Ch., **2**, 203, 1870; **4**, 353, 1871; Jb. Min., 55, 1879. Lithionpsilomelan *Laspeyres*, J. pr. Ch., **13**, 2, 1876.

A hydrated manganese ore containing (Winkler) 10 to 15 p. c. $Al_2O_3$, 1·2–1·4 p. c. $Li_2O$, and 12·6–15·4 p. c $H_2O$. Occurs in fine scales, also compact, botryoidal. H. = 3. G. = 3·14–3·36 Frenzel. Luster dull to metallic. Color bluish black. Streak blackish gray. Analyses, see Winkler, J. pr. Ch, **4**, 353, 1871, or 5th Ed., App. I, p. 9.

Found associated with quartz in many localities in the Schneeberg mining district, also occurs at Sayn, and near Siegen.

WAD. (A) BOG MANGANESE. Magnesia friabilis terriformis *Cronst.*, Min., 105, 1758. Earthy Ocher of Mang., Black Wad pt., *Kirwan*, Min., 1784. 1796. In amorphous and reniform masses, either earthy or compact; also incrusting or as stains. Usually very soft, soiling the fingers; less often hard to H. = 6. G. = 3·0–4·26; often loosely aggregated, and feeling very light to the hand. Color dull black, bluish or brownish black.

The mineral substances here included are mixtures of various oxides, chiefly of manganese ($MnO_2$, also MnO), cobalt, copper, with also iron, and from 10 to 20 p. c. water. They can hardly be regarded as representing distinct mineral species.

The following are the chief varieties; some other closely related substances are described in the pages 259, 260.

A. BOG MANGANESE. Consists mainly of oxide of manganese and water, with some oxide of iron, and often silica, alumina, baryta. The Derbyshire wad sometimes gives the angle of barite, with which mineral it is in part impregnated. The wad of Leadhills is pseudomorphous after calcite. *Groroilite* occurs in roundish masses of a brownish black color, and reddish brown streak; with H. sometimes 6–6·5; it is from Groroi in Mayenne, Vicdessos, and Cautern, in France. *Reissacherite* is an ore analyzed by Hornig which is remarkable for containing a large amount of water. *Wackenrodite* is a wad from Baden containing 12 p. c. Pb (5th Ed., anal. 6, p. 182). The name *wad* is of English origin. Huot's name *ouatite* is from the French spelling of wad. The *wad* of the Cumberland miners is graphite,—a wrong use of the word, says Mawe in his Mineralogy of Derbyshire.

B. ASBOLITE. or *Earthy Cobalt.* Wad containing oxide of cobalt, which sometimes amounts to 32 p. c. Named from *ἀσβόλη*, *soot* (or *Asbolan* from *ἀσβολαῖνω*, to soil like soot). Breithaupt's *kakochlor* includes the ore from Rengersdorf in Lausitz, having H. = 2–2·5, G. = 3·15–3·29.

C. LAMPADITE, or *Cupreous Manganese.* A wad containing 4 to 18 p. c. of oxide of copper, and often oxide of cobalt also. It graduates into black copper (Melaconite or Kupferschwärze). G. = 3·1–3·2. *Peloconite* is a brownish black variety, having a liver-brown streak; H. = 3; G. = 2·508–2·567; from Remolinos in Chili; cf. also Frenzel, Jb. Min., 801, 1873. *Lepidophæite* is a kind from Kamsdorf, Thuringia. Structure fine fibrous and scaly. Very soft, soiling the fingers. G. = 2·89–3·04. Luster silky, dull. Color and streak reddish brown, the latter shining. Analysis, Jenkins: $MnO_2$ 58·77, MnO 9·59, CuO 11·48, $H_2O$ 21·05 = 100·89.

Analyses of the various kinds of wad vary very widely, see 5th Ed., pp. 181, 182. Also the following: A. Gorgeu, Bull. Soc. Min., **13**, 27, 1890; impurities in small amount have been deducted.

| | $MnO_2$ | MnO | BaO | CaO | MgO | CoO | ZnO | CuO | PbO | $K_2O$ | $Na_2O$ | $H_2O$ |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 1. Loc. unknown | 66·2 | 7·9 | — | 5·0 | 2·0 | — | 1·6 | 0·2 | | *tr.* | 1·8 | [15·3] = 100 |
| 2. Romanèche | 68·1 | 7·6 | 16·2 | 1·7 | *tr.* | — | *tr.* | *tr.* | 0·3 | — | 0·8 | 5·3 = 100 |
| 3. Giessen | 83·1 | 7·1 | — | 0·26 | — | 0·5 | — | 0·5 | — | 4·05 | 1·0 | 3·49 = 100 |

The above ores are results of the decomposition of other ores—partly of oxides and sulphides, partly of manganesian carbonates. They occur at Clausthal, Ilmenau, Siegen, and many other places. Bog manganese is abundant in the counties of Columbia and Dutchess, N. Y., at Austerlitz, Canaan Centre, and elsewhere, where it occurs as a marsh deposit, and, according to Mather, has proceeded from the alteration of brown spar; also in the south-west part of Martinsburg, Lewis Co., in a swamp. There are large deposits of bog manganese at Blue Hill Bay, Dover, and other places in Maine.

*Asbolite* occurs at Riechelsdorf in Hesse; Saalfeld in Thuringia; at Nerchinsk in Siberia; at Alderley Edge in Cheshire; New Caledonia. An earthy cobalt occurs at Mine la Motte, Missouri, which contains 10 or 11 p. c. of oxide of nickel, besides oxide of cobalt and copper, with iron, lead, and sulphur; also near Silver Bluff, South Carolina, affording 24 p. c. of oxide of cobalt to 76 of oxide of manganese.

*Lampadite* is found at Schlackenwald, and at Kamsdorf near Saalfeld; at Lauterberg in the Harz. *Peloconite* is from Remolinos, Chili, where it occurs with chrysocolla, or malachite.

VARVICITE *Phillips*, Phil. Mag., **6**, 281, 1829, **7**, 284, 1830. Varvacite. An altered manganite, approaching wad in composition; from Warwickshire. Some similar substances are noted in 5th Ed., p. 182; another, from Austinville, Wythe Co., Va., has been analyzed by P. H. Walker (Am. Ch. J., **10**, 41, 1888):

G. = 3·27 $MnO_2$ 68·86 MnO 7·51 BaO 14·42 $H_2O$ 5·08 $SiO_2$ 1·98 $Fe_2O_3,Al_2O_3$ 2·23 = 100·08

## Appendix to Oxides.

**Bernonite** *Adam*, Tabl. Min., 73, 1869. Contains: $Al_2O_3$,CaO,$H_2O$.

**Delafossite** *C. Friedel*, C. R., **77**, 211, 1873. In small crystalline plates, cleavable into thin opaque laminæ. H. = 2·5. G. = 5·07. Color dark gray like graphite, with a more decided metallic luster. Streak blackish gray. Analysis, Friedel:

CuO 47·45 $Fe_2O_3$ 47·99 $Al_2O_3$ 3·52 = 98·96

B.B. fusible with difficulty, coloring the flame green. Easily soluble in hydrochloric acid, even in the cold. Found on yellowish white lithomarge from the region of Ekaterinburg, Siberia, perhaps also from Bohemia. Named for the mineralogist G. Delafosse.

**Hetærolite** *G. E. Moore*, Am. J. Sc., **14**, 423, 1877. Hetairite *Naumann-Zirkel*, Min., 11th Ed., p. 371, 1881. In botryoidal coatings with columnar-radiate structure. Brittle. H. = 5. G. = 4·933. Luster metallic to submetallic. Color black. Streak brownish black. Opaque. Contains zinc and manganese, and stated to be a zinc hausmannite, but no analyses published. Occurs intimately associated with chalcophanite (whence name from ἑταῖρος, *companion*) at the Passaic zinc mine, Sterling Hill, near Ogdensburg, Sussex Co., New Jersey.

**Heterogenite** *Frenzel*, J. pr. Ch., **5**, 404, 1872. Amorphous, massive in globular, reniform masses, with little luster. H. = 3. G. = 3·44. Color black, or blackish to reddish brown; streak dark brown. Composition, essentially, CoO.$2Co_2O_3 + 6H_2O$ (Frenzel). Analysis (after deduction of foreign constituents, Cu, Bi, etc.):

$\frac{2}{2}$ CoO 72·0 O 5·98 $H_2O$ 21·33 = 99·31

Soluble in dilute hydrochloric acid, with evolution of chlorine, leaving a residue. Occurs sparsely with calcite and pharmacolite in cobalt and nickel veins at Schneeberg; also at the St. Anton mine, Heubach, near Wittichen, Baden. It is a decomposition-product of smaltite.

**Heubachite.** Kobaltnickeloxydhydrat *F. Sandberger*, Ber. Ak. München, 238, 1876; Erzgänge, 413, 1885. In thin soot-like incrustations; in dendritic or small spherical aggregates. H. = 2·5. G. = 3·75. Color deep black. Streak submetallic. Composition perhaps $3(Co,Ni,Fe)_2O_3 + 4H_2O$. Analysis, Zeitschel, l. c.:

$Co_2O_3$ 65·50 $Ni_2O_3$ 14·50 $Fe_2O_3$ 5·13 $Mn_2O_3$ 1·50 $H_2O$ 12·59 = 99·22

Soluble in concentrated hydrochloric acid, with evolution of chlorine; the solution is deep bluish green, but on diluting with water becomes rose-red. Occurs as a secondary product coating barite at the St. Anton mine, in the Heubachthal, near Wittichen, Baden; also at the mine Eberhard, near Alpirsbach, Würtemberg.

**Hydrated Titanic Oxide.** Oxyde de titane hydraté *Gorceix*, Bull. Soc. Min., **7**, 179, 1884. In small flattened discs, like small beans. H. = 6. G. = 3·96. Color yellow, reddish, with brilliant luster, compact; also grayish with earthy fracture. They contain besides $TiO_2$ also $P_2O_5$, $V_2O_5$, $Al_2O_3$, and small quantities of iron, lime, cerium, didymium, and yttrium. B.B. decrepitate violently and yield acid water in the closed tube. Common in the diamond gravels of the valley of the Jequitinhonha near Diamantina, Brazil. They are called *favas* by the local miners. The existence of the same substance in the diamantiferous gravels was noted by Damour (Bull. Soc. G. Fr., **13**, 552, 1856).

**Hydrofranklinite** *W. T. Roepper*. Stated to be a new hydrous oxide of zinc, manganese, and iron. Occurs in small, very brilliant iron-black regular octahedrons; with highly perfect octahedral cleavage. H. = 4–4·5. G. = 4·06–4·09. From Sterling Hill, near Ogdensburg, Sussex Co., New Jersey. Not yet analyzed.

**Hydroplumbite** *Heddle*, Min. Mag., **8**, 201, 1889. In minute crystalline scales (hexagonal?), forming thin white flakes with pearly luster. Soluble in nitric acid, the solution showing the presence of lead alone. B.B. yields water. Inferred (but on very insufficient grounds) to be $3PbO.H_2O$. Observed with cerussite and pyromorphite upon galena. Locality doubtful, or perhaps from Cumberland or Leadhills.

**Namaqualite** *A. H. Church*, J. Ch. Soc., **23**, 1, 1870. In silky fibers and thin layers. H. = 2·5. G. = 2·49. Luster silky. Color pale blue. Transparent to translucent. Analysis, Church:

$Al_2O_3$ 15·29 CuO 44·74 MgO 3·42 CaO 2·01 $SiO_2$ 2·25 $H_2O$ 32·38 = 100·09

From Namaqualand, S. Africa. Approximates to $Al(OH)_3$. $2Cu(OH)_2$. $2H_2O$.

**Pelagite** *A. H. Church*, Min. Mag., **1**, 50, 1876. A name given by Church to the manganese nodules obtained by the Challenger Expedition from the bottom of the Pacific, between Japan and the Sandwich Is., at a depth of 2740 fathoms. Characters, as follows: Fracture conchoidal; fragile. H. = 3·5. Color brownish black. Powder between blackish brown and clove-brown. The nodules have a concretionary structure, consisting of concentric layers with a core of indurated red clay, and, in one case, of pumice. Anal., Church:

| $SiO_2$ | $MnO_2$ | $Al_2O_3$ | $Fe_2O_3$ | $H_2O$ | |
|---|---|---|---|---|---|
| 10·37 | 30·22 | 3·30 | 20·02 | 34·55[a] | Cl 0·71, MgO, CaO, CuO, $Na_2O$, Cl, $P_2O_5$, etc., 0·83 = 100 |

[a] At a red heat 10·0 p. c.

Other analyses by Schwager (quoted by Gümbel, Ber. Ak. München, 189, 1878). also by Dittmar (Rep. Chall. Ex.), by J. Y. Buchanan (Proc. Roy. Soc. Ed., **9**, 287, 1877; Ch. News, **44**, 253, 1881), of specimens from different localities, show a wide variation in composition. These nodules obviously do not represent a mineral species. Cf. also Report Challenger Exped., **1**, 1885.

RABDIONITE *F. von Kobell*, Ber. Ak. München, 46, 1870. Stalactitic, in columnar or rod-like forms. Very soft, soiling the fingers. G. = 2·80. Luster dull, after rubbing is greasy to submetallic. Color black. Streak dark brown. Analysis:

$Fe_2O_3$ 45·00 $Mn_2O_3$ 13·00 $Al_2O_3$ 1·40 CuO 14·00 MnO 7·61 CoO 5·10 $H_2O$ 13·50 = 99·61

B.B. fuses at 3 to a steel-gray, magnetic globule. Soluble in hydrochloric acid with evolution of chlorine, giving an emerald-green solution. From Nizhni Tagilsk in the Ural. Near asbolite. Named from *ῥάβδιον, a little rod.*

TRANSVAALITE *T. B. McGhie* and *John Clark*, Eng. Mng. J., **50**, 96, 1890. An oxidation-product of cobalt arsenide occurring in black nodular masses forming veins in quartzyte. H. = 4. G. = 3·846. Analysis:

| $Co_2O_3$ | CoO | NiO | $H_2O$ | $Fe_2O_3$ | $Al_2O_3$ | CaO | MgO | $SiO_2$ | $As_2O_5$ |
|---|---|---|---|---|---|---|---|---|---|
| 65·80 | 3·82 | 0·15 | 12·19 | 2·41 | 2·68 | 0·40 | 0·30 | 6·35 | 5·79 = 99·89 |

Dissolves readily in hydrochloric acid with evolution of chlorine. Occurs at the cobalt mine, 30 miles north of Middleburg, Transvaal, South Africa. Cf. heterogenite and heubachite, above; also winklerite.

WINKLERITE *Breithaupt*, Jb. Min., 816, 1872. Amorphous, massive. Fracture conchoidal. H. = 3. G. = 3·432. Luster dull. Color bluish black to violet-black. Streak dark brown. A mixture regarded as containing a hydrated oxide of cobalt and nickel. Analyses.—1, Winkler, after deducting iron sesquioxide and silica. 2, Iwaya, Jb. Min., **2**, 256, 1882; the material analyzed consisted nearly one-half of a copper-calcium arsenate, deducting which the results in *2a* are obtained, for which the formula $(Co,Ni)_2O_3 + 2H_2O$ is calculated.

| | | $As_2O_5$ | CuO | $Co_2O_3$ | CoO | NiO | CaO | $CO_2$ | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|---|---|
| 1. | | 10·83 | 13·89 | 10·86 | 33·10[a] | | 5·62 | 10·90 | 14·80 = 100 | [= 100·49 |
| 2. | G. = 3·72 | 20·50 | 15·01 | — | 23·80 | 12·98 | 9·27 | — | 12·12 | $Bi_2O_3$ 1·70, O 14·11 |
| *2a.* | | — | — | — | 46·2 | 25·2 | — | — | 20·6 | O 8·0 = 100 |

[a] Co : Ni = 11 : 1.

B.B. infusible, coloring the flame green. With the fluxes gives reaction for cobalt. Effervesces with hydrochloric acid, and the solution thus obtained upon heating evolves chlorine.

Found at Oria near Almeria in the Sierra Alhamilla, Spain, occurring with galapectite, also with erythrite and malachite. Formed (Breith.) by the gradual decomposition of erythrite. Named after Dr. Clemens Winkler.

# VI. Oxygen-salts.

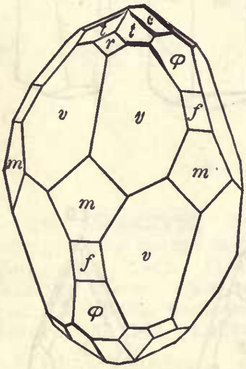
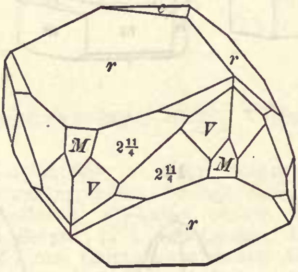
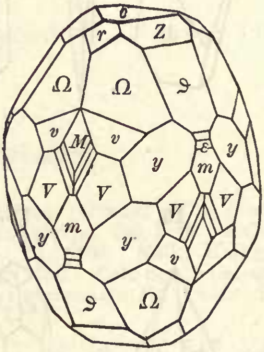
24.



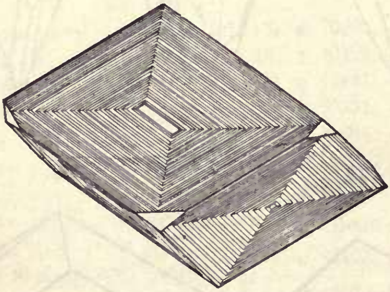
25.



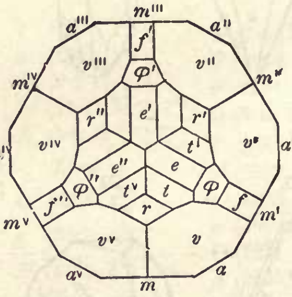
26.



27.



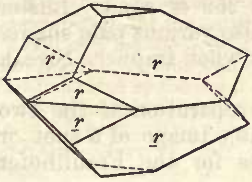
28.



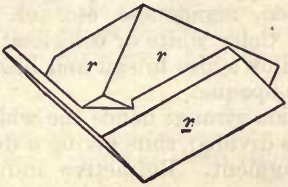
24, Derbyshire. 25, Rossie. 26, Canary Is., Hbg. ($\Omega = \frac{10}{17}^{\frac{35}{9}}$) 27, Port Henry, N. Y., Kemp—showing oscillatory combination of *r* with several scalenohedrons. 28, Basal projection of f. 24.

Habit of crystals very varied: from obtuse to acute rhombohedral (f. 1–9, 14); from thin tabular to long prismatic (f. 10–13); and scalenohedral of many types (f. 15–20); sometimes of wonderful complexity (cf. f. 26). The basal plane *c* often rough and sometimes exhibiting a pearly luster; the rhombohedron *r* not very common except in Iceland Spar; *e* $(01\bar{1}2)$, *f* $(02\bar{2}1)$, *M* $(40\bar{4}1)$, all common; $\phi$ $(05\bar{5}4)$ is the cuboid of Haüy (f. 4); the scalenohedron *v* $(21\bar{3}1)$ very common both alone and in combination, also *y* $(31\bar{5}1)$. Faces in the zone *rr′* over *e* (f. 28) often striated ∥ edge *r*/*r′*, also *e* when alone rounded over in this direction; striations in other zones common. Crystals grouped in parallel position, large scalenohedral crystals thus built up of minute rhombohedrons; also in rosettes and other forms.

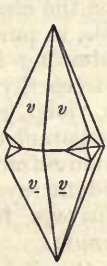
29.



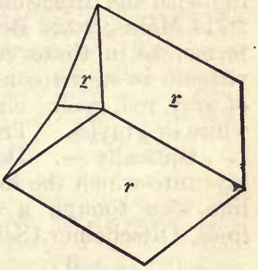
30.



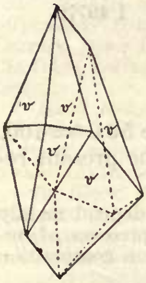
31.



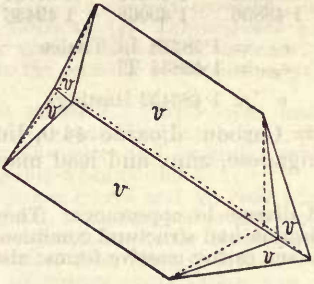
32.



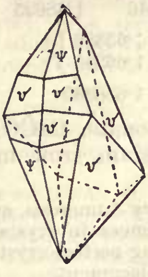
33.



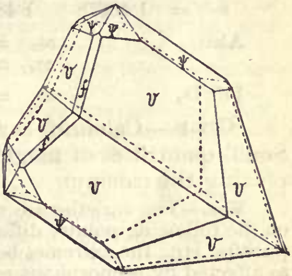
33*a*.



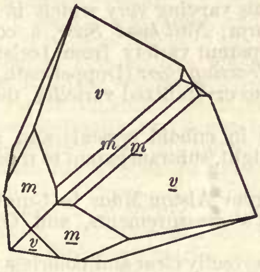
34.



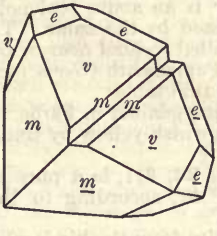
35.



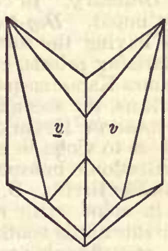
36.



37.



38.

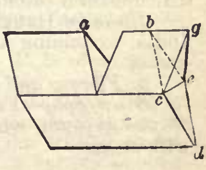


29, 30, Rossie, Pfd. 33–35, Guanajuato, Pirsson—the forms (also f. 36, 37) distorted by the extension of certain of the scalenohedral faces. 36, 37, England, Haid. 38, Sbk.

Twins[3]: (1) tw. pl. *c*, common, the crystals having the same vertical axis (f. 29–31). (2) tw. pl. *e* $(01\bar{1}2)$, very common, the vertical axes inclined 127° 29½′ and 52° 30½′ (f. 32–35); often producing twinning lamellæ as in Iceland Spar, which are, in many cases, of secondary origin as in granular limestones.

These twins can be readily formed artificially by the pressure of a dull-edged knife on the obtuse cleavage edge as at *a* (f. 39), the result being to cause the reversal of a portion, this taking place without loss of transparency and giving a re-entrant angle between *ced* and *ceg*; the corresponding twinning lamellæ can also be produced artificially. These twinning lamellæ are often connected with minute hollow channels (hohle Canäle of Rose) within, which produce a kind of asterism when a candle-flame is viewed through a cleavage mass.

39.



(3) Tw. pl. *r*, not common; the crystals have their vertical axes inclined 90° 46′ and 89° 14′, and have one cleavage face in

common (f. 36, 37). (4) tw. pl. $f\,(02\bar{2}1)$, rare (f. 38); the axes intersect at angles of 53° 46′ and 126° 14′.

Also fibrous, both coarse and fine; sometimes lamellar; often granular; from coarse to impalpable, and compact to earthy. Also stalactitic, tuberose, nodular, and other imitative forms.

Cleavage: $r$ highly perfect. Parting $\parallel e\ (01\bar{1}2)$ due to twinning, also $\parallel a$ less common, Mgg. Fracture conchoidal, obtained with difficulty. H. = 3, but varying with the direction on the cleavage face; earthy kinds softer. G. = 2·713 Gdt., 2·714 Malus, 2·723 Beud., in pure crystals, but varying somewhat widely in impure forms, as in those containing iron, manganese, etc. (cf. p. 269 *et seq.*). Luster vitreous to subvitreous to earthy. Color white or colorless; also various pale shades of gray, red, green, blue, violet, yellow; also brown and black when impure. Streak white or grayish. Transparent to opaque.

Optically −. Double refraction strong; hence the wide separation of the two rays into which the incident ray is divided, thus giving a double image of a spot or line seen though a cleavage fragment. Refractive indices for the Fraunhofer lines, Ditscheiner (Schrauf):

| | B | C | D | E | F | G | H |
|---|---|---|---|---|---|---|---|
| $\omega$ = | 1·65305 | 1·65454 | 1·65849 | 1·66362 | 1·66812 | 1·67642 | 1·68338 |
| $\epsilon$ = | 1·48378 | 1·48446 | 1·48625 | 1·48856 | 1·49066 | 1·49458 | 1·49770 |

Also $\omega_r$ = 1·65382 Li $\epsilon_r$ = 1·48418 Li Thalen
$\omega_{gr}$ = 1·66285 Tl $\epsilon_{gr}$ = 1·48834 Tl

For $D_2$ $\omega$ = 1·658389 $\epsilon$ = 1·486452 Hastings

**Comp.**—Calcium carbonate, $CaCO_3$ = Carbon dioxide 44·0, lime 56·0 = 100. Small quantities of magnesium, iron, manganese, zinc, and lead may be present replacing the calcium.

**Var.**—The varieties are very numerous, and diverse in appearance. They depend mainly on the following points: differences in crystallization and structural condition, presence of impurities, etc., the extremes being perfect crystals and earthy massive forms; also on composition as affected by isomorphous replacement.

### A. Varieties based chiefly upon crystallization and accidental impurities.

1. *Ordinary.* In crystals and cleavable masses, the crystals varying very widely in habit as already noted. *Dog-tooth Spar* is an acute scalenohedral form; *Nail-head Spar*, a composite variety having the form suggested by the name. The transparent variety from Iceland, used for polarizing prisms, etc., is called *Iceland Spar* or *Doubly-refracting Spar* (Doppelspath, *Germ.*). The names Kanonenspath and Papierspath (*Germ.*) are given to crystallized varieties, the first to long prisms, the second to very thin tables.

*Brunnerite* Esmark, from amygdaloid in Färöe, is calcite in cuboid crystals and massive, smalt-blue to violet in color, brownish-yellow by transmitted light, subtransparent to translucent, and chalcedonic in aspect.

*Reichite* Breith., B. H. Ztg., **24**, 311, is a pure calcite from Alston-Moor in Cumberland, white in color, with $rr' = 74° 40'$, according to Breithaupt's measurements, and G. = 2·666–2·677; this needs confirmation.

As regards color calcite varies from the kinds which are perfectly clear and colorless through yellow, pink, purple, blue, to brown and black. The color is usually pale except as caused by impurities. These impurities may be pyrite, native copper, malachite, sand, etc.; they are sometimes arranged in symmetrical form, as depending upon the growth of the crystals and hence produce many varieties.

*Fontainebleau limestone*, Lassonne, Mem. Ac. Paris, 1775, Chaux carbonatée quartzifère *H.*, 1801. Crystals from Fontainebleau and Nemours, France, which contain a large amount of sand, some 50 to 63 p. c. according to Delesse, with G. = 2·53–2·84. the latter from one containing 57 p. c. of sand. Similar forms occur at other localities, the rhombohedron $f\ (02\bar{2}1, -2)$ being the one commonly observed. A kind from Gersthof near Vienna consists of calcite and quartz grains in the ratio of 2 : 3 (Berwerth, Ann. Mus. Wien, **1**, 31 not., 1886). The well-known crystals from Heidelberg have lost their calcite and are pseudomorphs of red sandstone after scalenohedral calcite; similar forms occur in the Vosges.

*Hislopite* Haughton, Phil. Mag., **17**, 16, 1859. A grass-green cleavable calcite from Central India, containing about 17 p. c. of a siliceous material like glauconite, to which the color is owing.

2. *Fibrous and lamellar kinds.*

*Satin Spar* (Faserkalk, Atlasspath *Germ.*). Fine fibrous, with a silky luster. Resembles fibrous gypsum, which is also called satin spar, but is much harder than gypsum and effervesces with acids.

*Argentine* Kirwan, Min., 1, 104, 1794; *Schieferspath* Hofmann, Bergm., J., 188, 1789; Slate Spar. A pearly lamellar calcite, the lamellæ more or less undulating; color white, grayish, yellowish, or reddish.

*Aphrite,* in its harder and more sparry variety (*Schaumspath* Freiesleben), is a foliated white pearly calcite, near argentine; in its softer kinds (*Schaumerde* W., *Silvery Chalk* Kirwan, *Ecume de Terre* H.) it approaches chalk, though lighter, pearly in luster, silvery white or yellowish in color, soft and greasy to the touch, and more or less scaly in structure.

3. *Granular massive to cryptocrystalline kinds: Limestone, Marble, Chalk.*

*Granular limestone* or *Saccharoidal limestone,* so named because like loaf sugar in fracture. The texture varies from quite coarse to very fine granular, and the latter passes by imperceptible shades into *compact* limestone. The colors are various, as white, yellow, reddish, green, and usually they are clouded and give a handsome effect when the material is polished. When such limestones are fit for polishing, or for architectural or ornamental use, they are called *marbles.* (*a*) *Statuary marble* is pure white, fine grained, and firm in texture. The *Parian* marble from the island of Paros (the *Lychnites* of the ancients), *Pentelican* from the quarries near Athens, *Luni* marbles of the coast of Tuscany, and the *Carrara* of Modena, Italy, are among the best of statuary marbles. *Architectural* marble includes both white and colored. (*b*) The *Cipolin* of Italy is white, with pale greenish shadings from green talc; it does not stand the weather well. (*c*) *Giallo antico* of Italy is ocher-yellow to cream yellow, with some whitish spots. (*d*) The *Siena,* or *Brocatello de Siena,* is yellow, veined or clouded with bluish red, having sometimes a tinge of purple. (*e*) The *Mandelato* is a light red with yellowish white spots. A red kind from Tiree (or Tyree), one of the inner Hebrides, Scotland, has different shades of red, as carnelian, rose red, flesh-red, reddish white; one from Tennessee is clouded with brownish and purplish red. (*f*) The *Bardiglio* is gray with crowded dark well defined cloudings, consisting partly of serpentine, from Corsica. (*g*) *Turquois-blue* marble, from the quarries of Seravezza near Carrara, has a fine grayish blue color, veined with white. (*h*) *Verd-Antique* is clouded green, the color, owing to the presence of serpentine, yellowish green to bluish green (see also serpentine).

*Hard compact limestone.* Varies from nearly pure white, through grayish, drab, buff, yellowish, and reddish shades, to bluish gray, dark brownish gray, and black, and sometimes variously veined. The colors dull, excepting ocher-yellow and ocher-red varieties. Many kinds make beautiful marble when polished.

(*a*) *Black,* (*b*) *yellow,* (*c*) *red* and (*d*) *fetid* kinds are common. Red oxide of iron produces different shades of red, from flesh-red or paler to opaque blood-red and brownish red, according to the proportions present; the latter Hausmann names *Hæmatoconite* (from *ἅιμα, blood,* and *κόνις, powder,* Handb., 1304, 1847), as in the marble *Rosso antico* of Italy. The hydrated oxide causes yellowish to opaque ocher-yellow and yellowish brown; the deeper, *Sideroconite* of Hausmann (ib., 1306). Shades of green are due to iron protoxide, chromium oxide, iron silicate. The black marbles colored by carbonaceous matter are named *Anthraconite* (from *ἄνθραξ, coal*), by v. Moll, *Lucullan* by John, and *Lucullite* by Jameson; they include the *Marmor Luculleum* of Pliny. The *Nero Antico* of the Italians belongs here. The bituminous or *fetid* limestones are also called anthraconite when black; and also, from the odor, *Swinestone* (syn. *Stinkstone; Stinkstine, Saustein, Stinkkalk,* Germ.), some being light gray in color.

The *Portor* (*d*), called sometimes Egyptian marble, is of black color, handsomely veined with yellow dolomite, and comes from Porto-Venere, near Spezia; the rock is of the lower Lias. (*e*) *Panno-di-Morte* (Death's Robe) of Italy is black with some white fossil shells. (*f*) *Marble of Languedoc* is fine deep red or brownish red, with some white and gray due to fossils, and is from St. Beaumé in France. (*g*) *Griotte,* from the Dept. of Herault, France, has a reddish brown base, with somewhat regularly arranged spots of clear red, and some whitish round spots due to goniatites. (*h*) *Sarencolin* marble, from the Pyrenees, is deep red mixed with gray and yellow. (*i*) Bird's-eye marble is gray, with whitish crystalline points, and is from central New York.

(*k*) *Shell-marble* includes kinds consisting largely of fossil shells; (*l*) *Madreporic* marble, those containing corals; (*m*) *Encrinal,* those containing encrinal (crinoidal) remains. (*n*) *Lumachelle* or *fire-marble* is a dark brown shell-marble, with brilliant fire-like or chatoyant internal reflections proceeding from the shells, from Bleiberg in Carinthia; and another kind, with the shells yellow, comes from Astrachan.

(*o*) *Ruin-marble* is a kind of a yellow to brown color, showing, when polished, figures bearing some resemblance to fortifications, temples, etc., in ruins, due to infiltration of iron oxide: from Florence, Italy.

(*p*) *Lithographic stone* is a very even-grained compact limestone, usually of buff or drab color; as that of Solenhofen.

(*q*) *Breccia marble* is made of fragments of limestone cemented together, and is often very beautiful when the fragments are of different colors, or are embedded in a base that contrasts well. The colors are very various.

(*r*) *Pudding-stone* marble consists of pebbles or rounded stones cemented. It is often called improperly breccia marble.

(*s*) *Hydraulic limestone* is an impure limestone which after ignition sets, i.e., takes a solid form under water, due to the formation of a silicate. The French varieties contain 2 or 3 p. c. of magnesia, and 10 to 20 of silica and alumina (or clay). The varieties in the United States contain 20 to 40 p. c. of magnesia, and 12 to 30 p. c. of silica and alumina. A variety worked extensively at Rondout, N. Y., afforded Professor Beck (Min. N. Y., 78): $CO_2$ 34·20, CaO 25·50, MgO 12·35, $SiO_2$ 15·37, $Al_2O_3$ 9·13, $Fe_2O_3$ 2·25. Iron is rather prejudicial to it than otherwise. Vicat observes that in the best French there are 20 to 30 p. c. of clay, and in that only moderately good 10 to 12 p. c. An impure limestone of France, which needs no sand for making the cement, it containing calcite 54 p. c., clay 31, iron oxide 15 = 100, is called *plaster-cement* (Dufr. Min.).

*Soft compact limestone.* (*a*) *Chalk* is white, grayish white, or yellowish, and soft enough to leave a trace on a board. The consolidation into a rock of such softness may be owing to the fact that the material is largely the hollow shells of rhizopods.

The *creta* of the Romans (usually translated *chalk*) was mostly a white clay, true chalk being little known to the ancients. The kind described by Pliny as the most inferior kind of cretaceous earth, and as used for marking the feet of slaves, was probably true chalk.

(*b*) *Calcareous marl* (Mergelkalk *Germ.*) is a soft earthy deposit, often hardly at all consolidated, with or without distinct fragments of shells; it generally contains much clay, and graduates into a calcareous clay.

*Concretionary massive.* (*a*) *Oolite* (Rogenstein *Germ.*) is a granular limestone, but its grains are minute rounded concretions, looking somewhat like the roe of fish, the name coming from *'ωόν*, *egg*. It occurs among all the geological formations, from the Lower Silurian to the most recent, and it is now forming about the coral reefs of Florida. A more or less completely silicified oolite occurs near College Center, Penn. (Barbour and Torrey, Am. J. Sc., **40**, 246, 1890). (*b*) *Pisolite* (Erbsenstein *W.*) consists of concretions as large often as a small pea, or even larger, the concretions having usually a distinct concentric structure. It is formed in large masses in the vicinity of the Hot Springs at Carlsbad in Bohemia.

Minute concretionary forms having a spherical concentric structure within and externally the form of a regular pentagonal dodecahedron (not pyritohedron) have been obtained from a calcareous spring near Eagle Rock, Idaho; their form has not been explained.

*Deposited from calcareous springs, streams, or in caverns, etc.*

(*a*) *Stalactites* (Tropfstein *Germ.*) are the calcareous cylinders or cones that hang from the roofs of limestone caverns, and which are formed from the waters that drip through the roof; these waters hold some calcium bicarbonate in solution, and leave calcium carbonate to form the stalactite when evaporation takes place. Stalactites vary from transparent to nearly opaque; from a crystalline structure with single cleavage directions to coarse or fine granular cleavable and to radiating fibrous; from a white color and colorless to yellowish gray and brown.

(*b*) *Stalagmite* is the same material covering the floors of caverns, it being made from the waters that drop from the roofs, or from sources over the bottom or sides; cones of it sometimes rise from the floor to meet the stalactites above. It consists of layers; but these are very irregularly curved, or bent, owing to the knobs and conelets that are made over the floor; and polished specimens generally owe much of their beauty to the agate-like or onyx-like bandings.

Stalagmite, or a solid kind of travertine (see below) when on a large scale, is the *Alabastrites* or alabaster stone, in part (if not wholly) of Theophrastus, Pliny, and other ancient writers; that is, the stone of which ointment vases, of a certain form called *alabasters*, were made. (See GYPSUM, p. 936.) A locality near Thebes, now well known, was largely explored by the ancients, and the material has often been hence called *Egyptian alabaster*. It was also formerly called *onyx* and *onychites* because of its beautiful banded structure; Horace, in the 3d book of his Odes, speaks of an ointment vase of onyx. Pliny mentions columns of "onyx," or "alabastrites," that were 32 ft. in height, and mentions Damascus as affording a kind whiter than that of Thebes. In the arts it is often now called *Oriental Alabaster* or *onyx marble;* and sometimes also *Gibraltar-stone*, from the occurrence of the material in a cavern at Gibraltar. Very beautiful marble of this kind is obtained in Algeria. *Mexican onyx* is a similar material obtained from Tecali, Puebla, Mexico; also in a beautiful brecciated form from the extinct crater of Zempoaltepec in southern Mexico. Similar kinds occur in Missouri, Arizona, San Luis Obispo Co., California.

(*c*) *Calc-sinter, Travertine, Calc Tufa.* Travertine (*Confetto di Tivoli*) is of essentially the same origin with stalagmite, but is distinctively a deposit from springs or rivers, especially where in large deposits, as along the river Anio, at Tivoli, near Rome, where the deposit is scores of feet in thickness. It has a very cavernous and irregularly banded structure, owing to its mode of formation. It is the *Lapis Tiburtinus* of Vitruvius and Pliny; the word *travertine* being a corruption of *tiburtine*. It includes also, especially under the name of *calc tufa*, cellular depositions from the waters of small springs or sources which often contain fossil leaves, twigs, moss, nuts, or seed, etc. The *Osteocollus* (Beinwelle, Beinbruch) Gesner (p. 31, 1565), "qui ossa fracta intra corpus sumptus," as was thought at the time (*osteocolla* of later authors), is, as long since shown, a cellular calc tufa, consisting of incrustings of fragments of reeds or other marsh plants. It means *bone-glue*. *Inolite*, Gallitzin, is also calc-sinter.

(*d*) *Agaric mineral;* Rock-milk (*Bergmich*, *Montmilch*, Germ.) is a very soft white material, breaking easily in the fingers, deposited sometimes in caverns, or about sources holding lime in solution.

(*e*) *Rock-meal* (*Bergmehl* Germ., *Farina Fossilis* Bruckm., etc.) is white and light, like cotton, becoming a powder on the slightest pressure. It is an efflorescence, and is common near Paris, especially at the quarries of Nanterre.

### B. Varieties based upon composition.

1. *Dolomitic calcite.* Contains magnesium carbonate, thus graduating toward true dolomite.

2. *Baricalcite. Neotyp* Breith., Handb., **2**, 313, 1841. Grayish white, and occurring in rhombohedrons *f* (02$\bar{2}$1, − 2), *rr'* = 74° 57', Breith. G. = 2·819–2·840. Contains some barium carbonate. From Cumberland, England. A "barytocalcite" from Långban, Sweden, has been analyzed by Lundström (G. För. Förh., **3**, 291, 1877): $CO_2$ 29·32, BaO 50·89, CaO 17·64, FeO 0·42, MnO 0·24, MgO 0·40, PbO 0·37, insol. 0·70 = 99·98. It occurs in white granular masses with G. = 3·46; associated with hedyphane, hausmannite, etc. According to Des Cloizeaux this mineral is rhombohedral with a cleavage angle of about 75°. Bourgeois notes that attempts to reproduce barytocalcite have uniformly led to the formation of a rhombohedral carbonate of calcium and barium, Bull. Soc. Min., **12**, 464, 1889.

3. *Strontianocalcite* Genth, Proc. Ac. Sc. Philad., **6**, 114, 1852. In opaque white crystals, occurring in globules which have a surface consisting of the terminations of acute rhombohedrons; H. = 3·5. Contains some strontium carbonate, and hence gives a decided red flame before the blowpipe.

4. *Ferrocalcite.* Contains ferrous carbonate, and turns brown on exposure; one variety of unknown source gave Hunt 4·64 $FeCO_3$, Dana Min., 438, 1854. G. = 2·715.

5. *Manganocalcite,* pt. *Spartaite* Breith., B. H. Ztg., **17**, 53, 1858. *Calcimangite* Shepard. Contains manganese carbonate and becomes black on exposure. Spartaite occurs with franklinite and zincite at Franklin Furnace and Sterling Hill, N. J. *rr'* = 75° 2½' Breith. G. = 2·808–2·818. Jenzsch found in it: 11·09 $MnCO_3$, 0·58 $ZnCO_3$, and G. = 2·788, Pogg., **96**, 147, 1855. A similar variety from Långban gave: 11·06 $MnCO_3$, 2·06 $BaCO_3$, Sjögren, G. För. Förh., **4**, 111, 1878; another 2·80 $MnCO_3$, 1·09 $ZnCO_3$, Lindgren, ib., **5**, 557, 1885. In one from Wester Silfberg, Weibull found 6·98 MnO with G. = 2·804, *rr'* = 75° 29', Min. Mitth., **7**, 110, 1885; other varieties contained much more. A specimen from Negaunee, Lake Superior, gave C. Percy Wilcox (priv. contr.): $\frac{2}{2}$ $CO_2$ 42·37, CaO 39·22, MnO 18·56 = 100·15, G. = 2·84; here Ca : Mn = 3 : 1 approx. See further under rhodochrosite.

6. *Zincocalcite.* Contains some zinc carbonate; one specimen from Olkucz, Poland, gave Gibbs 4·07 ZnO, another from Altenberg 1·06–1·65 ZnO, Monheim (Rg.). Cf. manganocalcite above.

7. *Plumbocalcite* Johnston, Ed. Phil. J., **6**, 79, 1829. White to yellowish and reddish brown; from Wanlockhead and Leadhills, Scotland. Contains variable amounts of lead carbonate. 1·2–5·2 p. c. and G = 2·7–2·8, Collie, J. Ch. Soc., **55**, 95, 1889; 2·7–9·5 p. c. with G. = 2·72–2·74, Lex., Bull. Soc. Min., **8**, 36, 1885. Cf. Traube, Jb. Min., **2**, 278, 1887. Schöffel found in rhombohedral crystals from Bleiberg: 23·75 $PbCO_3$; in a coating with silky luster 14 p. c. $PbCO_3$ and G. = 2·92; also in the underlying limestone 2 to 9 p. c. $PbCO_3$ and G. = 2·88; Höfer, Min. Kärnt., 1870.

**Pyr., etc.**—In the closed tube sometimes decrepitates, and, if containing metallic oxides, may change in color. B.B. infusible, but becomes caustic, glows, and colors the flame reddish yellow; after ignition the assay reacts alkaline; moistened with hydrochloric acid imparts the characteristic lime color to the flame. In borax dissolves with effervescence, and if saturated yields on cooling an opaque, milk-white, crystalline bead. Varieties containing metallic oxides color the borax and salt of phosphorus beads accordingly. With soda on platinum foil fuses to a clear mass; on charcoal at first fuses, but later the soda is absorbed by the coal, leaving an infusible and strongly luminous residue of lime. In the solid mass effervesces when moistened with hydrochloric acid, and fragments dissolve with brisk effervescence even in cold acid.

**Obs.**—Calcite, in its various forms, is one of the most widely distributed of minerals. Beds of sedimentary limestone, formed from organic remains, shells, crinoids, corals, etc., yield on metamorphism crystalline limestone or marble, and in connection with these crystallized calcite and also deposits in caves of stalactites and stalagmites often occur. Common with the zeolites in cavities and veins of igneous rocks as a result of alteration, and similarly though less common with granite, syenite, etc. A frequent mineral in metalliferous deposits, with lead, copper, silver, etc. Deposited from lime-bearing waters as calc sinter, travertine, etc., especially in connection with hot springs as at the Mammoth Hot Springs in the Yellowstone region.

Some of the best known localities for crystallized calcite are the following: Andreasberg in the Harz; the mines of Freiberg, Annaberg, Schneeberg, Bräunsdorf, in Saxony; Auerbach on the Bergstrasse; Oberstein on the Nahe; Altenberg near Aachen; Kapnik in Hungary; Aussig in Bohemia; Bleiberg in Carinthia; Traversella in Piedmont; Elba. In England at Alston Moor and Egremont in Cumberland (Min. Mag., **8**, 149, 1889); Matlock, Derbyshire; Beer Alston in Devonshire; at numerous points in Cornwall; Weardale in Durham; Stank mine, Lancashire; in Northumberland. In twin crystals of great variety and beauty at Guanajuato, Mexico.

The Iceland spar has been obtained from Iceland near Helgustadir on the Eskefiord. It occurs in a large cavity in basalt. The crystals, usually showing the fundamental rhombohedron, are often coated with tufts of stilbite. It also occurs in the north-western part of the island near Djupidalr on the Breitifiord. The quantity is limited and is likely to be exhausted. The locality was early described by Dx., Bull. Soc. G., **4**, 769, 1847 (Min., **2**, 114, 1874); later see Zs. G. Ges., **40**, 191, 1888; Zs. Instrumentenkunde, **8**, 63, 1888. Also Thoroddsen, G. För. Förh., **12**, 247, 1890, who gives sectional figures of the deposit.

In the U. States, crystallized calcite occurs in *N. York*, in St. Lawrence and Jefferson Cos., especially at the Rossie lead mine; crystals highly modified, and often transparent even when large; one nearly transparent, in the cabinet of Yale University, weighs 165 pounds; often covered in part by crystals of galena; at the Natural Dam, 2 m. from Gouverneur, in the same vicinity, good crystals; also at the Wilson vein in Gouverneur, and the Jepson vein in Rossie; at the Parish ore bed in Gouverneur, fine geodes, in specular iron; in Jefferson Co., near Oxbow, on the land of Mr. Benton, from a decomposing limestone, large crystals sometimes as clear as Iceland spar; rose and purple varieties very beautiful; some large crystals weighing 100 lbs. and upward; 4 m. S. of Oxbow, in Antwerp, a vein of calcite and lead, which affords beautiful cleavage masses of white, purple, and brownish shades; also interesting crystals; in Essex Co., town of Moriah, on Mill Brook, near Port Henry, crystals of calcite in white limestone; dog-tooth spar, in Niagara Co., near Lockport, with pearl spar, celestite, selenite, and anhydrite; in Onondaga Co., near Camillus, along the railroad; good crystals in Herkimer Co., 1 m. S. of Little Falls, in the bed of a small stream; in Lewis Co., at Leyden and Lowville, and at the Martinsburg lead mine; on the western bank of Dry Sugar River, near Boonville, Oneida Co.; at Anthony's Nose on the Hudson, formerly groups of large tabular crystals; at Watertown, *agaric mineral*, covering the sides of a cave; at Schoharie, fine *stalactites* in many caverns, of which Ball's cave is the most famous; at Camillus and Schoharie (near the barite locality), *fibrous*, in considerable abundance, and at De Long's Mill, St. Lawrence Co., of a fine satin luster. In *Maine*, at Thomaston, lenticular and prismatic crystals, common. In *N. Hamp.*, at the iron mines, Franconia, *argentine*. In *Mass.*, at Williamsburg and Southampton, *argentine*. In *Conn.*, at the lead mine, Middletown, in crystals. In *N. Jersey*, at Bergen, fine crystallizations of yellow calcite, with datolite, etc.; at Franklin Furnace, a pink variety containing $MnCO_3$, and good cleavage specimens. In *Penn.*, in York Co., Iceland spar. In *Virginia*, at the celebrated Wier's cave, *stalactites* of great beauty; also in the large caves of *Kentucky*. At the Lake Superior copper mines, splendid crystals of wonderful variety and complexity of form often containing scales of native copper. At Warsaw, *Illinois*, in great variety of form, lining geodes and implanted on quartz crystals; at Quincy. At Hazelgreen, *Wisconsin*.

In *Missouri*, with dolomite near St. Louis; also with sphalerite at Joplin and other points in the zinc region in the south-western part of the state, the crystals usually scalenohedral and of a wine-yellow color. Fine transparent cleavage masses at the gadolinite locality in Llano Co., *Texas*. From the Bad Lands, South Dakota. In *Arizona*, at the Copper Queen mine, Bisbee, often green with enclosed malachite.

In Nova Scotia, at Partridge I., a wine-colored calcite, and other interesting varieties.

On the various localities furnishing marbles in the U. S., see Merrill: The Collection of Building and Ornamental Stones in the U. S. National Museum (Report Smithsonian Inst., Pt. II, pp. 277–648, 1885–86); a summary is also given of foreign marbles and their localities.

**Artif.**—On formation by fusion in alkaline chlorides; see Bourgeois, Bull. Soc. Min., **5** 111, 1882.

**Alt.**—Calcite occurs under the forms of dolomite, calamine, siderite, malachite, azurite, gypsum, smithsonite, barite, fluorite, limonite, göthite, hematite, minium, meerschaum, chlorite, quartz, chalcedony, garnet, feldspar, mica, pyrolusite, hausmannite, manganite, marcasite, galena, sphalerite, native copper. Cf. Bischof, Chem. Geol.; Blum, Pseud., 1843, and Nachträge; Roth, Chem. Geol., **1**, 1879. Sandstone in the form of calcite, see Fontainebleau limestone, p. 266.

**Ref.**—[1] Result obtained by Malus, Théorie de la double Réflexion, etc., p. 98, 1810, Paris; by Wollaston, Phil. Trans., p 159, 1812; also by Biot, Mohs, and usually accepted; recently confirmed by Hastings, who gives $rr' = 74^\circ\ 54'{\cdot}93$ for 20° C., Am. J. Sc., **35**, 68, 1888. For other determinations, cf. Kupffer, $rr' = 74^\circ\ 55'{\cdot}5$, Preisschrift, 65, 1825; Breithaupt, 74° 54¼′–74° 55′, Handb., 209. 1841, Schw. J., **24**, 49, 1828; Rath, $rr' = 74^\circ\ 55'{\cdot}2$; Koksharov, $rr' = 74^\circ\ 56'$, Min. Russl., **7**, 59, 1875.

Variation in composition brings a considerable change in angle (cf. Breith.). The cleavage angle also changes remarkably with variation in temperature; an elevation of 100° increases the normal angle $rr'$ by 8′ 34½″, Mitsch., Pogg., **10**, 137, 1827, Abh. Ak. Berlin, 201, 1825.

[2] This list gives the common forms, and some which are rarer; the complete list includes between 150 and 200 forms, with many more that are doubtful. An early and exhaustive monograph on the species was given by Zippe, Uebersicht der Krystallgestalten des rhomb. Kalkhaloides, Denkschr. Ak. Wien, 3, 109, 1852. Sella in 1856 gave a list of forms (Quadro). For later full and in part annotated lists of forms, see Dx., Min., 2, 97, 1874; Irby, Inaug. Diss., Bonn, 1878 (Zs. Kr., 3, 612); Gdt., Index, **1**, 371, 1886; Sansoni (for Andreasberg), Mem. Acc. Linc., **19**, 1884, Zs. Kr., **10**, 545, 1885.

Of the many important memoirs devoted to the subject, in addition to these named, the following may be mentioned (see further the literature given by Irby, Sansoni, Gdt., as well as the Mineralogy of Haüy, of Lévy, Breithaupt, Hausmann, et al.): Count de Bournon, Traité de la chaux carbonatée, etc., London, 1808; Sella, Min. Sarda, 1856; Hochstetter, Denksch. Ak. Wien, **6**, 89, 1854; Hbg., many original observations, Min. Not., **3–12**; Rath, many valuable papers, 1867–1882, Pogg. Ann., **132**, **135**, Erg., **5**, **152**, **155**, **158**, also Zs. Kr., **1**, 604, **6**, 540, et al. Recent memoirs include: Morton, Arendal, etc., Öfv. Ak. Stockh., **41**, No. 8, 65, 1884; Thürling, Andreasberg, Jb. Min., Beil., **4**, 327, 1886; Sansoni, Belgium, Zs. Kr., **11**, 352, 1886; Id., Monte Catini, Att. Acc. Torino, **23**, 1888; Id., Sweden and Norway, Giorn. Min., **1**, 129, 1890; Cesàro, Rhisnes, Ann. Soc. G. Belg. Mem., **16**, 1889. Some new forms are noted on twins by Pirsson, Am. J. Sc., **41**, 61, 1891.

[3] On *twins*, see Sella, Min. Sarda, 1856; Rath, Pogg., **132**, 534, 1867, et al. E. S. D., Min Mitth., 180, 1874, Groth, Min.-Samml., 120, 1878, but cf. Mgg., Jb. Min., **1**, 84, 1883. On the structural phenomena connected with twinning, cf. Brewster, Optics; Pfaff, Pogg., **107**, 336, 1859; Rose, "Die hohlen Canäle," Abh. Ak. Berlin, 1868; Reusch, "Gleitflächen," Pogg., **132**, 441, 1867; Baumh., Zs. Kr., **3**, 588, 1879. Also Mügge, Jb. Min., **1**, 32, 81, 1883, who gives full literature, and ib., **1**, 247, 1889.

On *elasticity*, Baumgarten, Pogg., **152**, 369, 1874; Vater, Zs. Kr., **11**, 577, 1886; Voigt, Wied., **39**, 412, 432, 1890. *Hardness*, Exner, Härte Kryst., 45, 1873. THINOLITE *King*, Rep. Geol. 40th Parallel, **1**, 508, 1878. A tufa deposit of calcium carbonate occurring on an enormous scale in north-western Nevada, covering an area of several miles and 20 to 60 feet thick; named from θίς, *shore*, as being a shore deposit of the Quaternary lake, L. Lahontan. It also occurs about Mono Lake, California. It forms layers of interlaced crystals of a pale yellow or light brown color and often skeleton structure except when covered by subsequent deposit of calcium carbonate.

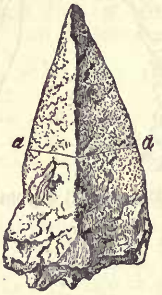
1.



2.

The crystals are prismatic or acute pyramidal in form (f. 1), sometimes solid, again open skeleton forms with layers converging in one direction, and affording a rectangular rib-work on the cross-section (f. 2, section at *a a*, f. 1). The original mineral is shown to have had an acute pyramidal form approximating at least to the tetragonal type. Occasional forms resembling the Sangerhausen barley-corn pseudomorphs (after celestite, see p. 907) occur.

The original mineral from which the thinolite has resulted is in doubt; gay-lussite has been suggested, but does not agree with the observed form. A possible derivation from a calcium chlorocarbonate ($CaCO_3.CaCl_2$ or $CaCO_3.2NaCl$) has suggested itself on the ground of a similarity in form of the thinolite to the pseudomorphs of cerussite after phosgenite (f. 3, p. 292). See further King, l. c.; E. S. D., U. S. G. Surv., Bull. **12**, 1884; Russell, 3d Ann. Rep. U. S. G. Surv., 1883, Monograph, **11**, 1885.

PREDAZZITE *Petzholdt* pt., Beitr. Geogn. Tyrol, 194, 1843. PENCATITE *Roth*, Zs. G. Ges., **3**, 140, 143, 1851. Massive granular rocks from the neighborhood of Predazzo in southern Tyrol, described at first as mineral species (See 5th Ed., p. 708), but later shown to be mixtures essentially of calcite and brucite. See Damour, Bull. Soc. G. France, **4**, 1050, 1847; Hauenschild, Ber. Ak. Wien, **60**, 795, 1869; Lemberg, Zs. G. Ges., **24**, 229, 1872; cf. also Roth, Ch. Geol., **1**, 234, 1879.

Pencatite was named after Count Marzari Pencati.

**271. DOLOMITE.** Pierres calcaires très-peu effervescentes avec les acides *D. Dolomieu*, J. de Phys., **39**, 1, 1791. Dolomie *Saussure*, Voy. Alpes, § 1929, 1796. Twins[14]: tw. pl. (1) *c*, the vertical axes in common; (2) *m*, which is also a plane of symmetry for the twin; (3) *a*, complementary twins, with rhombohedral symmetry; also double twins by the combination of two of these laws; (4) *r*, analogous to calcite.

Habit rhombohedral, usually *r* or *M;* the presence of tetartohedral forms, rhombohedrons of the second or third series, very characteristic. The *r* faces often striated horizontally, also commonly curved (cf. f. 2, p. 276) or made up of subindividuals, and thus passing into saddle-shaped forms (f. 2). Also in imitative shapes; amorphous, granular, coarse or fine, and grains often slightly coherent.

Cleavage: *r* perfect. Fracture subconchoidal. Brittle. H.=3·5–4. G.=2·8–2·9; 2·883 Dmr.; 2·83 A. Sella. Luster vitreous, inclining to pearly in some varieties. Color white, reddish, or greenish white; also rose-red, green, brown, gray, and black. Transparent to translucent. Etching figures[14] correspond in shape to the tetartohedral form. Optically −. Refractive indices:

$$\omega_y = 1{\cdot}68174\ \text{Na} \qquad \epsilon_y = 1{\cdot}50256\ \text{Na, Fizeau (Dx.)}$$

**Comp.**—Carbonate of calcium and magnesium $(Ca,Mg)CO_3$; for normal dolomite $CaMgC_2O_6$ or $CaCO_3.MgCO_3$ = Carbon dioxide 47·8, lime 30·4, magnesia 21·7 = 100, or Calcium carbonate 54·35, magnesium carbonate 45·65 = 100. Varieties occur in which the ratio of the two carbonates varies from 1 : 1. The carbonates of iron and manganese also sometimes enter; rarely cobalt and zinc carbonates.

**Var.**—1. *Structural,* including:

(*a*) *Crystallized. Pearl spar* includes rhombohedral crystallizations with curved faces having a pearly luster.

(*b*) *Columnar;* also fibrous or pisolitic.

*Miemite*, from Miemo, Tuscany, is either in crystals, columnar, or granular, and pale asparagus-green in color.

(*c*) *Granular*, or *saccharoidal*, constitutes many of the kinds of white statuary marble, and white and colored architectural marbles, names of some of which have been mentioned under calcite.

(*d*) *Compact massive*, like ordinary limestone. Many of the limestone strata of the globe are here included, and much *hydraulic limestone*, noticed under calcite.

(*e*) *Compact porcellanous*, *Gurhofian* or *gurhofite;* snow-white and subtranslucent, with a conchoidal fracture, sometimes a little opal-like; from Gurhof, in lower Austria.

*Also depending on Composition.*

2. *Normal dolomite* is Ca : Mg = 1 : 1; most common especially in crystals. Cf. anals. 1–20, 5th Ed., p. 683, also Haushofer, Ber. Ak. München, 220, 1881. The dolomite from the Gebroulaz glacier gave A. Sella (l. c.): $CO_2$ 47·67, CaO 31·37, MgO 21·23 = 100·27; G. = 2·83.

The ratio may also be 3 : 2, 2 : 1 (includes *gurhofian*), 3 : 1, etc., but in some cases the variation is due to mechanical admixture, and much so-called dolomite is merely a magnesian calcite; this is especially true of the massive forms. Cf. 5th Ed., p. 683. In *conite* the ratio is 1 : 3.

3. *Ferriferous; Brown spar*, in part. Contains ferrous carbonate, and as the proportion increases it graduates into ankerite (q.v.). The color is white to brown, and becomes brownish on exposure through the oxidation of the iron. A columnar kind, from Traversella, containing 10 p. c. of $FeCO_3$, has been called *Brossite;* G. = 2·915. *Tharandite*, from Tharand, near Dresden, is crystallized, and contains 4 p. c. of $FeCO_3$.

4. *Manganiferous.* Colorless to flesh-red. A variety from Freiberg, with 5·2 p. c. $MnCO_3$, had $rr' = 73° 37'$, G. = 2·83 Ettling, Lieb. Ann., **99**, 204, 1856. One from Kapnik with 5·4 p. c. $MnCO_3$ had $rr' = 73° 44'$, G. = 2·89 Ott, Haid. Ber., **2**, 403, 1847.

5. *Cobaltiferous.* Colored reddish. A kind from Přibram gave 7·4 p. c. $CoCO_3$, G. = 2·921 Gibbs, Pogg., **71**, 564, 1847.

6. *Zinciferous.* Altenberg, with 1·4 $ZnCO_3$, Monheim. Also Bleiberg, with 2·4 $ZnCO_3$, G. = 2·87, $rr' = 73° 32'$, Gintl, Zeph., Lotos, 1877.

**Pyr., etc.**—B.B. acts like calcite, but does not give a clear mass when fused with soda on platinum foil. Fragments thrown into cold acid, unlike calcite, are only very slowly acted upon, if at all, while in powder in warm acid the mineral is readily dissolved with effervescence. The ferriferous dolomites become brown on exposure.

**Obs.**—Massive dolomite constitutes extensive strata, called limestone strata, in various regions, as in the dolomite region of the southern Tyrol. Crystalline and compact varieties are often associated with serpentine and other magnesian rocks, and with ordinary limestones. Some of the prominent localities are: Leogang in Salzburg; Schemnitz and Kapnik in Hungary; Freiberg in Saxony. In Switzerland, at Bex, in crystals; also in the Binnenthal massive and in colorless crystals; Traversella in Piedmont; Campolongo; Gebroulaz glacier in Savoy with sellaite (see p. 164); the lead mines at Alston in Cumberland, etc. Guanajuato, Mexico.

In the U. States, in *Vermont*, at Roxbury, large, yellow, transparent crystals of the rhomb-spar variety, in talc. In *Rhode Island*, at Smithfield, a coarse cleavable variety, occasionally presenting perfect crystals, with white talc in calcite. In *N. Jersey*, at Hoboken, white hexagonal crystals, and in rhombohedrons. In *N. York*, at Lockport, Niagara Falls, and Rochester, with calcite, celestite, and gypsum; also at Glenn's Falls; in Richmond Co., at the quarantine, crystallized dolomite, in rhombohedrons, and at the Parish ore bed, St. Lawrence Co.; on Hustis's farm in Phillipstown, a variety resembling *gurhofite*, with a semi-opaline appearance and a fracture nearly like porcelain; at the Tilly Foster iron mine, Brewster, Putnam Co., with magnetite, chondrodite. In saddle-shaped crystals with the sphalerite of Joplin, *Missouri*. In *N. Car.*, at Stony Point, Alexander Co., in fine rhombohedral crystals (*r* with *c*) having nearly plane faces.

Named after Dolomieu (1750–1801), who announced some of the marked characteristics of the rock in 1791—its not effervescing with acids, while burning like limestone, and solubility after heating in acids. He observes in his paper that, as early as 1786, he had found the white marble of many of the ancient statues and monuments of Italy to consist of this peculiar rock; and eighteen months before the date of his paper he discovered "immense quantities of similar limestones" in the Tyrol.

**Alt.**—Dolomite occurs altered to siderite, calamine, steatite, limonite, hematite, göthite, pyrolusite, and quartz.

**Ref.**—[1] Wollaston, Mohs, Fizeau, Biot, Dx.; this angle is somewhat variable. The tetartohedral character was first established by Tschermak, Min. Mitth., **4**, 102, 1881. [2] Mlr., Min., 581, 1852. Cf. also Dx., Min., **2**, 127, 1874; Kk., Min. Russl., **7**, 5, 1875; Gdt., Index, **1**, 513, 1886; Becke, who identifies the ± r, ± l forms, Min. Mitth., **10**, 142, 1888, **11**, 224, 1890. The list here given is essentially that of Becke (1890); he discusses several other doubtful forms (Dx., etc.), but overlooks A. Sella. Kk. calculates angles for several forms but not as observed planes, viz.: $50\bar{5}1$, $60\bar{6}1$, and $70\bar{7}1$, etc., breunnerite, ib., p. 181; these are included by Gdt.

[3] J. D. D., Hoboken, Min., 441, 1854. [4] Q. Sella, Traversella, Min. Sarda, 13 et seq., 1856. [5] Hbg., Binnenthal, Min. Not., **3**, 13, 1860; also ib., **7**, 41, where $\frac{10}{13}$ (= $\frac{4}{5}$, cf. Hintze[11]) is misprinted $\frac{10}{3}$, and thence taken by Kk. [6] Rath, Binnenthal, Pogg., **122**, 399, 1864. [7] Kenng., Binnenthal, Min. Schweiz, 301, 1866. [8] Dx., l. c. [9] Groth, Min.-Samml. Strassb., 127, 1878. [10] Tsch., l. c. **271A. Ankerite.** Dolomite pt. Brown Spar and Pearl Spar pt. Paratomes Kalk-Haloid *Mohs*, Grundr., **1**, 536, 1822, **2**, 116, 1824. Rohwand, Wandstein, *Styrian Miners*. Ankerit *Haid.*, Min. Mohs, **1**, 100, 1825. Tautoklin *Breith.*, Char., 70, 1832, Uib., 20, 1830. Parankerit *Boricky*, Min. Mitth., 47, 1876.

Rhombohedral; $rr' = 73° 48'$ Styria, Mohs. In rhombohedral crystals; also crystalline massive, coarse or fine granular, and compact.

Cleavage: $r$ perfect. H. = 3·5–4. G. = 2·95–3·1. Luster vitreous to pearly. Color white, gray, reddish. Translucent to subtranslucent.

**Comp.**—A sub-species intermediate between calcite, magnesite, and siderite; that is, containing the carbonates of calcium, magnesium, iron, and in small quantities manganese. Formula $CaCO_3.(Mg,Fe,Mn)CO_3$.

Normal ankerite is $2CaCO_3.MgCO_3.FeCO_3$ = Calcium carbonate 50·0, magnesium carbonate 21·0, iron carbonate 29·0 = 100.

Boricky writes the formula $CaFeC_2O_6 + n(CaMgC_2O_6)$ with $n$ varying from $\frac{1}{2}$ to 10; those varieties with $n = 2$ or more, he calls *parankerite*. Normal ankerite would then be $CaFeC_2O_6 + CaMgC_2O_6$, and normal parankerite $CaFeC_2O_6 + 2CaMgC_2O_6$ (or $3CaCO_3.2MgCO_3.FeCO_3$).

For analyses see 5th Ed., p. 685, also Rg., Min. Ch., 229, 1875. Boricky, l. c.

The ankerite from Antwerp, Jefferson Co., N. Y., gave D. N. Harper, priv. contr.:

$CaCO_3$ 55·98 $MgCO_3$ 28·57 $FeCO_3$ 14·66 $MuCO_3$ 1·66 = 100·87

Others from Nova Scotia gave Louis, Proc. N. S. Inst., **5**, 47, 1878–79:

| | | | | |
|---|---|---|---|---|
| G. = 2·998 | $CaCO_3$ 53·75 | $MgCO_3$ 22·75 | $FeCO_3$ 22·70 | $MnCO_3$ 0·80 = 100 |
| | 71·23 | 9·34 | 16·41 | 2·65 insol. 0·53 = 100·16 |

*Tautoclin* Breith. is a grayish white variety, containing about 15 p. c. $FeCO_3$, and having $rr' = 73° 44'$; also G. = 2·961, Ettling; from Beschertglück, near Freiberg in Saxony.

**Pyr., etc.**—B.B. like dolomite, but darkens in color, and on charcoal becomes black and magnetic; with the fluxes reacts for iron and manganese. Soluble with effervescence in the acids.

**Obs.**—Occurs with siderite at the Styrian mines; also at Lobenstein, Freiberg, Schneeberg, Siegen, etc. With the hematite of northern New York (sometimes called siderite). In Nova Scotia near Londonderry, Colchester Co.

Named after Prof. Anker of Styria.

**272. MAGNESITE.** Kohlensaurer Talkerde *Mitchell & Lampadius* (first anal.), Samml. pr. Ch. Abh., 3, 241. Reine Talkerde, Talcum carbonatum, *Wern.*, Ludwig, **2**, 154, 1803. Magnesite pt. *Brongn.*, Min., **1**, 489, 1807. Magnesit *Karst.*, Tabell., 48, 92, 1808. Carbonate of Magnesia. Magnésie carbouatée *Fr.* Kohlénsaure Talkerde, Talkspath, *Germ.* Baudisserite *Delameth*, Min., **2**, 1812. Giobertite *Beud.*, Tr., 410, 1824. Breunnerite *Haid.*, Min. Mohs, **1**, 411, 1825. Breunerite. Walmstedtite *Leonh.*, Handb., 297, 1826. Brown Spar pt.

Rhombohedral; tetartohedral[4](?). Axis: $\dot{c} = 0·81123$; $0001 \wedge 10\bar{1}1 = 43° 7\frac{3}{4}'$, $rr' = {*}72° 36\frac{1}{3}'$ Koksharov[1].

**Forms**[2]: $c$ (0001, $O$), $m$ ($10\bar{1}0$, $I$), $a$ ($11\bar{2}0$, $i$-2), $r$ ($10\bar{1}1$, $R$), $f$ ($02\bar{2}1$, $-$ 2)[8], $v$ ($21\bar{3}1$, $1^3$)[3]; also an undetermined negative scalenohedron[4].

Crystals rare, usually rhombohedral, also prismatic. Commonly massive; granular cleavable to very compact; earthy.

Cleavage: $r$ perfect. Fracture flat conchoidal. Brittle. H. = 3·5–4·5. G. = 3·0–3·12, cryst.; 3·083, Scaleglia, Becke; 3–3·2, ferriferous. Luster vitreous; fibrous varieties sometimes silky. Color white, yellowish, or grayish white, brown. Transparent to opaque. Optically −. Double refraction strong.

**Comp.**—Magnesium carbonate, $MgCO_3$ = Carbon dioxide 52·4, magnesia 47·6 = 100. Iron carbonate is often present.

**Var.**—1. *Ordinary.* (*a*) *Crystallized*, rare. (*b*) *Lamellar*, cleavable. (*c*) *Compact*, fine granular. (*d*) *Compact*, and like unglazed porcelain in fracture. (*e*) *Earthy;* being mixed with hydrated silicate of magnesia or sepiolite (meerschaum); including the *Baudisserite*, from Baudissero, near Turin, which has some resemblance to chalk, and adheres to the tongue. Even the purer varieties of compact magnesite usually contain more or less of the silicate.

*Pinolite* Rumpf (Min. Mitth., 265, 1873) is a rock consisting largely of milk-white magnesite crystals with clay slate filling the spaces between them, from Wald in Styria, from the Semmering, etc.

2. *Ferriferous, Breunnerite;* containing several p. c. of FeO; G. = 3–3·2; white, yellowish, brownish, rarely black and bituminous; often becoming brown on exposure, and hence called *Brown Spar*.

The name *Breunnerite* was originally given by Haidinger (after M. Breunner) to the variety analyzed by Stromeyer containing 5 to 10 p. c. iron protoxide (or 8 to 17 p. c. of carbonate); and *Walmstedite* to an included kind from the Harz, differing only in containing a little more manganese protoxide than usual (2 p c.). The breunnerite from Hall, Tyrol, gave Foullon: $MgCO_3$ 79·13, $FeCO_3$ 19·14, $MnCO_3$ 2·04 = 100·31, Jb. G. Reichs., **38**, 2, 1888.

For analyses see 5th Ed., pp. 686, 687.

**Pyr., etc.**—B.B. resembles calcite and dolomite, and like the latter is but slightly acted upon by cold acids; in powder is readily dissolved with effervescence in warm hydrochloric acid.

**Obs.**—Found in talcose schist, serpentine and other magnesian rocks, also gypsum; as veins in serpentine, or mixed with it so as to form a variety of verd-antique marble (*magnesitic ophiolite* of Hunt); also, in Canada, as a rock, more or less pure, associated with steatite, serpentine, and dolomite. The breunnerite variety has been found in a meteorite from Orgueil, Dx.

Occurs at Hrubschütz in Moravia, where it was first discovered by Mitchell; at Kraubat and Tragössthal, Styria; Maria-Zell in Styria; Flachau in Salzburg; Greiner in the Zillerthal, Tyrol; Gross-Reifling in the Ennsthal in prismatic crystals in gypsum; at Frankenstein in Silesia; Snarum, Norway; Baudissero and Castellamonte in Piedmont; at other localities mentioned above.

In America, at Bolton, Mass., in indistinctly fibrous masses, traversing white limestone; at Lynnfield, Cavendish, and Roxbury, Mass., mixed with or veining serpentine; at Barehills, near Baltimore, Md.; in Penn., in crystals at West Goshen, Chester Co.; near Texas, Lancaster Co.; in Tulare, Alameda, Mariposa, and Tuolumne Cos., California. A white saccharoidal magnesite resembling statuary marble has been found as loose blocks on an island in the St. Lawrence River, near the Thousand Island Park. Also occurs with serpentine, dolomite, steatite, in Brome Co., Quebec.

In Canton Upata, Venezuela, near Mission Pastora, looking like porcelain in the fracture, as observed by N. S. Manross.

Delametherie, in his Théorie de la Terre, **2**, 93, 1795, uses the name magnesite for the carbonate of magnesia, sulphate, nitrate, and muriate, and the carbonate is placed first in the series. Brongniart, in his Mineralogy, **3**, 489, 1807, applies the name to a group, including (1) the carbonate called *Mitchell's magnesite*, (2) meerschaum, (3) the Piedmont magnesite, and (4) other siliceous varieties. As both Brongniart and Delametherie gave the *first* place to the carbonate, the name magnesite would rightly fall to it in case of the division of the group. Karsten, in his Tabellen, 1808, recognized this division of the species, and formally gave to the carbonate the name *magnesite*. The German mineralogists have followed Karsten, as should have been done by all. But in France, Beudant, in 1824, gave the name *giobertite* to the *carbonate*, leaving *magnesite* for the silicate, and most of the French mineralogists have followed Beudant. Giobert analyzed only the siliceous variety from Baudissero, the true composition of the mineral having been ascertained by Lampadius, somewhat earlier, from specimens brought by Mitchell from Moravia.

The name *Breunnerite* is spelled also Breunerite. Haidinger gives the former.

**Ref.**—[1] Tyrol, G. = 3·118, Min. Russl., **7**, 181, 1875. This angle varies for different localities, *e.g.*, Pfitsch, 72° 37½′ Mitsch.; Snarum 72° 32′ Breith.; Greiner, Tyrol, 72° 37½′, G. = 3·17, Zeph.; Maria-Zell, 72° 31′ Rumpf; Gross-Reifling, Ennsthal, 72° 44½′ Foullon, Vh. G. Reichs., 334, 1884; Scaleglia, 72° 33·6′ Becke, Min. Mitth., **11**, 250, 1890. [2] Rumpf, Maria-Zell, Min. Mitth., 263, 1873. [3] A. Sella, Gebroulaz, the crystals, hexagonal prisms (*a*) in anhydrite, were identified as magnesite by angles ($cr$ = 43° 16′), not analyzed, Mem. Acc. Linc., 4, Nov. 13, 1887. [4] Becke, Scaleglia, l. c.

**272A. Mesitite.** Mesitinspath pt. *Breith.*, Pogg., **11**, 170, 1827. Mesitin *Breith.*, Pogg., **70**, 148, 1847.

PISTOMESITE. Mesitin pt. *Breith.*, Pogg., **11**, 170, 1827. Pistomesit *Breith.*, Pogg., **70**, 146, 1847.

Rhombohedral; $rr'$ = 72° 42′ to 72° 46′ Breith. In rhombohedral crystals; also coarse granular.

Cleavage: $r$ perfect. H. = 3·5–4. G. = 3·33–3·42. Luster vitreous, inclining to pearly. Color yellowish white, yellowish gray, yellowish brown. Streak nearly white or colorless. Transparent to subtranslucent.

**Comp., Var.**—A sub-species intermediate between the ferruginous variety of magnesite, breunnerite, and siderite.

1. MESITITE $2MgCO_3,FeCO_3$ = Magnesium carbonate 59·2, iron carbonate 40·8 = 100. $rr'$ = 72° 46′. G. = 3·35–3·36 Br. Usually in flat rhombohedrons ($e$, $01\bar{1}2$) with rounded faces.

2. PISTOMESITE $MgCO_3.FeCO_3$ = Magnesium carbonate 42·0, iron carbonate 58·0 = 100. $rr'$ = 72° 42′. G. = 3·42 Br.

**Anal.**—1, W. Gibbs, Pogg., **71**, 566, 1847. 2, Fritsche, ib., **70**, 147, 1847. 3, Patera, Haid. Ber., **2**, 296, 1847. 4, Fritsche, l. c. 5, Ettling, Lieb. Ann., **99**, 203, 1853.

| MESITITE. | | G. | $CO_2$ | FeO | MgO | CaO | |
|---|---|---|---|---|---|---|---|
| 1. Traversella | | | 46·05 | 26·61 | 27·12 | 0·22 | = 100 |
| 2. " | | 3·35 | 45·76 | 24·18 | 28·12 | 1·30 | = 99·36 |
| 3. Werfen | $rr' = 72° 40'$ | 3·33 | 45·84 | 27·37 | 26·76 | — | = 99·97 |
| PISTOMESITE. | | | | | | | |
| 4. Thurnberg | | 3·42 | 43·62 | 33·92 | 21·72 | — | = 99·26 |
| 5. " | | 3·437 | $\frac{2}{2}$ 44·57 | 33·15 | 22·29 | — | = 100·01 |

**Pyr., etc.**—B.B. blackens and becomes magnetic. But slightly acted upon in mass by acids; readily dissolved with effervescence when in powder by hot hydrochloric acid.

**Obs.**—*Mesitite* is from Traversella, Piedmont; Werfen, with lazulite.

*Pistomesite* is from Thurnberg, near Flachau, in Salzburg; also at Traversella in Piedmont.

Mesitite is named from μεσίτης, *a go-between*. it being intermediate between magnesite and siderite; pistomesite is from πιστός and μεσίτης, named by Breithaupt after he had already used mesitine, and because pistomesite is nearer the middle between siderite and magnesite.

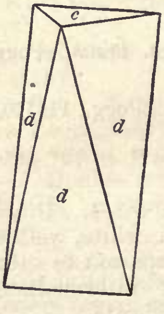
1.

2.



3.

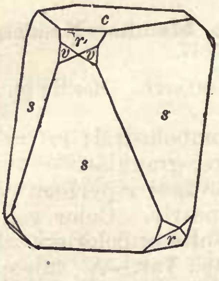


Fig. 1, Curved form, Haid. 2, 3, Cornwall.

Twins: tw. pl. $e$; often with inclosed twinning lamellæ. Crystals commonly rhombohedral $r$ or $e$, the faces often curved and built up of sub-individuals. Often cleavable massive to coarse or fine granular. Also in botryoidal and globular forms, subfibrous within, occasionally silky fibrous; compact and earthy.

Cleavage: *r* perfect. Fracture uneven or subconchoidal. Brittle. H. = 3·5–4. G. = 3·83–3·88 Dmr. Luster vitreous, inclining to pearly. Color ash-gray, yellowish gray, greenish gray, also brown and brownish red, rarely green; and sometimes white. Streak white. Translucent to subtranslucent. Optically —. Double refraction strong. Etching-figures in part symmetric, in part asymmetric, Tschermak.

**Comp.**—Iron protocarbonate, $FeCO_3$ = Carbon dioxide 37·9, iron protoxide 62·1 = 100 (Fe = 48·2 p. c.). Manganese may be present, also magnesium and calcium.

**Var.**—1. *Ordinary.* (*a*) *Crystallized.* (*b*) *Concretionary* = *Spherosiderite;* in globular concretions, either solid or concentric scaly, with usually a fibrous structure. (*c*) *Granular* to *compact massive.* (*d*) *Oolitic,* like oolitic limestone in structure. (*e*) *Earthy,* or stony, impure from mixture with clay or sand, constituting a large part of the clay iron-stone of the Coal formation and other stratified deposits; H. = 3–7, the last from the silica present; G. = 3·0–3·8, or mostly 3·15–3·65.

The varieties based on composition include, besides the nearly pure iron carbonate, also

2. *Manganiferous.* Containing several per cent of manganese carbonate. The *oligonspar* of Breithaupt, or *oligonite,* has 25 p. c. MnO, *rr'* = 72° 56'; G. = 3·714–3·745; color yellowish to between flesh- and iron-red; streak yellowish white; remarkably phosphorescent when heated.

3. *Magnesian.* Containing magnesium carbonate, and but little manganese. The *sideroplesite,* Breith., from Pöhl, has 12 p. c. $MgCO_3$, with *rr'* = 72° 54' Breith.; G. = 3·616–3·660. Here belong some varieties from Londonderry, Nova Scotia, analyzed by Louis, Trans. N. S. Inst., **5**, 50, 1878–79. Zepharovich obtained from a cleavage rhombohedron from Salzburg 10·5 p. c. MgO, *rr'* = 72° 54¾', and G. = 3·699.

4. *Calciferous.* Containing 20 p. c of calcium carbonate and looking like some calamine, the color green; from Altenberg. The *siderodot* of Breithaupt is a calciferous siderite from Radstadt in Salzburg, having G. = 3·41.

For analyses, see 5th Ed., p. 690.

**Pyr., etc.**—In the closed tube decrepitates, gives off $CO_2$, blackens and becomes magnetic. B.B. blackens and fuses at 4·5. With the fluxes reacts for iron, and with soda and niter on platinum foil generally gives a manganese reaction. Only slowly acted upon by cold acid, but dissolves with brisk effervescence in hot hydrochloric acid. Exposure to the atmosphere darkens its color, rendering it often of a blackish brown or brownish red color.

**Obs.**—Occurs in many of the rock strata, in gneiss, mica slate, clay slate, and as clay ironstone in connection with the Coal formation and many other stratified deposits. It is often associated with metallic ores. At Freiberg it occurs in silver mines. In Cornwall it accompanies tin. It is also found accompanying copper and iron pyrites, galena, chalcocite, tetrahedrite. Occasionally it is to be met with in trap rocks as *spherosiderite.*

In the region in and about Styria and Carinthia this ore forms extensive tracts in gneiss, which extend along the chain of the Alps, on one side into Austria, and on the other into Salzburg. At Harzgerode in the Harz, it occurs in fine crystals in gray-wacke; also in Cornwall of varied habit at many localities; at Alston-Moor, and Tavistock, Devonshire. Fine cleavage masses occur with cryolite in Greenland.

The *Spherosiderite* occurs in dolerite at Steinheim near Hanau and Dransfeld near Göttingen and Dransberg, and many other places. Clay iron-stone, which is a siliceous or argillaceous carbonate of iron, occurs in coal beds near Glasgow; also at Mouillar, Magescote, etc., in France, etc.

In the United States, in *Vermont,* at Plymouth. In *Mass.,* at Sterling. In *Conn.,* at Roxbury, an extensive vein in quartz, traversing gneiss; at Monroe, Lane's mine, in small quantities. In *N. York,* a series of important basins occur in Columbia Co., near Burden, they belong to the Hudson River Epoch of the Lower Silurian; at the Rossie iron mines, St. Lawrence Co. In *N. Carolina,* at Fentress and Harlem mines. The argillaceous carbonate, in nodules and beds (clay iron-stone), is abundant in the coal regions of Penn., Ohio, and many parts of the country. In a clay-bed under the Tertiary along the west side of Chesapeake Bay for 50 m. A magnesian variety (like sideroplesite) occurs at Londonderry, Colchester Co., Nova Scotia.

Named *Spherosiderite* by Hausmann in 1813, from the concretionary variety, and retained by him for the whole. Haidinger reduced the name to *Siderite,* the prefix *sphero* being applicable only to an unimportant variety. Beudant's name *Siderose* has an unallowable termination. *Chalybite,* Glocker, should yield to Haidinger's earlier name siderite, as recognized by v. Kobell and Kenngott.

**Alt.**—Siderite becomes brown or brownish black on exposure, owing to the oxidation of the iron and its passing to *limonite;* and by a subsequent loss of water, it may pass to *hematite* or to *magnetite,* the last at times a result of deoxidation of the $Fe_2O_3$ by organic substances. It also changes by substitution, or through the action of alkaline silicates, to *quartz.*

**Ref.**—[1] Phil. Trans., 159, 1812. [2] See Lévy, Heuland, **3**, 162, 1837; Breith., Lobenstein, Pogg., **58**, 279, 1843; Mlr., Min., 586, 1852. Kenng. describes crystals from Tavistock with a negative scalenohedron ($-4^2$) but gives no measurements, Pogg., **97**, 99, 1856. Gdt., Index, **1**, 539, 1886. [3] Dx., Min., **2**, 142, 1872. [4] Klein, Jb. Min., **1**, 256, 1884.

THOMÄITE *Mayer*, Jb. Min., 200, 1845. An iron carbonate, occurring in pyramidal crystallizations which are said to be orthorhombic; also massive. G. = 3·10. Luster pearly. From the Bleis-Bach, in the Siebengebirge. Named after Prof. Thomä of Wiesbaden.

*Junckerite* of Dufrénoy (l. c.) was described as having the same characters, but proved to be only common siderite; and the same fate may befall thomäite. Named after M. Juncker, director of mines at Poullaouen.

274. **RHODOCHROSITE.** Magnesium acido aëreo mineralisatum *Bergm.*, Sciagr., 1782 (without descr. or loc.). Rother Braunsteinerz [= Red Manganese Ore], Rothspath, Magnesium ochraceum rubrum, Oxide de manganèse couleur de rose, pt., *of later part of* 18*th cent.* (it being confounded with the silicate analyzed by Ruprecht in 1782, and Bergmann's announcement being doubted). Luftsaures Braunsteinerz (or Carbonate, after Bergm.) pt. *Lenz*, Min., **2**, 1794 (with mention of druses of small crystals in "Rhomben," others in "Pyramiden," but with cit. of Ruprecht's anal.). Lampadius's anal. of a Kapnik sp'n. in his Pr. Ch. Abh., **3**, 239, 1800), *Hausm.*, ib., 1081, 1813. Carbonate of Manganese. Manganspath *Wern.* Dialogite *Jasche*, Germar, Schw. J., **26**, 119 = Blättrige Rothmanganerz *Jasche*, Kl. Min. Schrift., 4, 1817. Diallogite (wrong orthogr.). Rosenspath, Himbeerspath, *Breith.*, Handb., 228, 229, 1841 (Char., 67, 68, 1832). Manganosiderit Bayer, Vh. Ver. Brünn, **12**, May 10, 1873. Manganocalcit *Breith.*, Pogg., **69**, 429, 1846. Rodocrosite *Ital.*

Rhombohedral. Axis $\dot{c} = 0{\cdot}81840$; $0001 \wedge 10\bar{1}1 = 43° 22' 50''$ Sansoni[1].

**Forms**[2]: $a$ $(11\bar{2}0, i\text{-}2)$  $e$ $(01\bar{1}2, -\frac{1}{2})$  $\chi$ $(07\bar{7}2, -\frac{7}{2})$[4]?  $v$ $(21\bar{3}1, 1^3)$[3]
$c$ $(0001, O)$  $r$ $(10\bar{1}1, R)$  $f$ $(02\bar{2}1, -2)$[3]  $t$ $(21\bar{3}4, \frac{1}{4}{}^3)$[3]?  $y$ $(32\bar{5}1, 1^5)$[4]

$cr = 43° 23'$  $rr' = 73° 0'$  $vv' = {}^*74° 52'$  $yy' = 70° 47\frac{1}{2}'$
$ce = 25° 17\frac{1}{2}'$  $ee' = 43° 26'$  $vv^{v} = 35° 23'$  $yy^{v} = 45° 26'$
$cf = 62° 7'$  $ff' = 99° 54'$  $vv^{vi} = 48° 30'$  $yy^{vi} = 30° 15'$

Distinct crystals not common; usually the rhombohedron *r*; also *e*, with rounded striated faces. Cleavable, massive to granular massive and compact. Also globular and botryoidal, with columnar structure, sometimes indistinct; incrusting.

Cleavage: *r* perfect. Fracture uneven. Brittle. H. = 3·5–4·5. G. = 3·45–3·60 and higher. Luster vitreous inclining to pearly. Color shades of rose-red; yellowish gray, fawn-colored, dark red, brown. Streak white. Translucent to subtranslucent. Optically −. Double refraction strong.

**Comp.**—Manganese protocarbonate, $MnCO_3$ = Carbon dioxide 38·3, manganese protoxide 61·7 = 100. Iron carbonate is usually present, and sometimes the carbonates of calcium, magnesium, zinc and rarely cobalt.

**Var.**—1. *Ordinary.* Pure $MnCO_3$ or nearly so, in crystals, but more commonly cleavable massive to indistinctly crystalline. Cf. remarks below, Ref. [1].

2. *Ferriferous.* Containing several per cent up to nearly 40 p. c. of $FeCO_3$. A cleavable variety from Branchville, Ct., gave Penfield 16·8 p. c. $FeCO_3$, $rr' = 73° 11'$, G. = 3·76, Am. J. Sc., **18**, 50, 1879. *Manganosiderite* is a Hungarian variety, resembling sphærosiderite, with 38·8 $FeCO_3$.

3 *Calciferous. Manganocalcite.* Contains calcium carbonate. The original from Schemnitz was flesh-red columnar. G. = 3·037 Br.; an early analysis gave: $MnCO_3$ 67·48, $FeCO_3$ 3·22, $CaCO_3$ 18·81, $MgCO_3$ 9·97 = 99·48, Rg., Pogg., **68**, 511, 1846; a later examination, however, showed it to be a mixture of a carbonate and silicate, Rg., Min. Ch. Erg., 157, 1886; and this is confirmed by Dx., Bull. Soc. Min., **7**, 72, 1884. It was supposed to be isomorphous with aragonite, but Krenner proves it to be rhombohedral, cf. Nat. Ber. aus Ungarn, **1**, 201, **2**, 355, 1884, and Zs. Kr., **8**, 242, 1883, **9**, 288, 1884. A variety from Wester Silfberg belongs here, G. = 3·09; analysis: $CO_2$ 40·59, MnO 24·60, FeO 6·95, CaO 26·71, insol. 1·15 = 100, Weibull, Min. Mitth., **7**, 110, 1885. See also p. 269.

A cleavable kind from Franklin Furnace, N. J., gave Roepper $MnCO_3$ 43·54, $FeCO_3$ 0·76, $CaCO_3$ 50·40, $MgCO_3$ 5·69 = 100·39. G. = 3·052. Am. J. Sc., **50**, 37, 1870; it was called *roepperite* by Kenngott, Jb. Min., 188, 1872.

4. *Zinciferous.* Contains zinc carbonate. A specimen from the Trotter mine, Mine Hill, Franklin Furnace, N. J., gave P. E. Browning: $MnCO_3$ 73·78, $ZnCO_3$ 2·28, $CaCO_3$ 20·37, $MgCO_3$ 3·74, $FeCO_3$ 0·35, $Fe_2O_3$ 0·16 = 100·68. G. = 3·47, Am. J. Sc., **40**, 375, 1890.

**Pyr., etc.**—B.B. changes to gray, brown, and black, and decrepitates strongly, but is infusible. With salt of phosphorus and borax in O.F. gives an amethystine-colored bead, in R.F. becomes colorless. With soda on platinum foil a bluish green manganate. Dissolves with effervescence in warm hydrochloric acid. On exposure to the air changes to brown, and some bright rose-red varieties become paler.

**Obs.**—Occurs commonly in veins along with ores of silver, lead, and copper, and with other ores of manganese.

Found at Schemnitz and Kapnik in Hungary; Nagyág in Transylvania; near Elbingerode in the Harz; at Freiberg in Saxony; at Diez near Oberneisen in Nassau; at Daaden, Rheinprovinz; at Moet-Fontaine in the Ardennes, Belgium; at Glendree in the County of Clare, Ireland, where it forms a layer 2 inches thick below a bog, and has a yellowish gray color; botryoidal at Hartshill in Warwickshire.

It has been observed in a pulverulent form, coating triplite, at Washington, Conn., on the land of Joel Camp; at Branchville with manganesian phosphates in a vein of albitic granite; in New Jersey, with franklinite at Mine Hill, Franklin Furnace. In Colorado, at the John Reed mine, Alicante, Lake Co., in beautiful clear rhombohedrons (*r*) up to ½ inch across; also at the Oulay mine, near Lake City, in flat rhombohedrons (*e*). In Montana, at Butte City, in rhombohedrons. Abundant at the silver mines of Austin, Nevada. At Placentia Bay, Newfoundland, in slates, fawn-colored and brown.

Named *rhodochrosite* from *ῥόδον*, *a rose*, and *χρῶσις*, *color;* and *dialogite*, from *διαλογή* *doubt.* The latter name is attributed to Jasche by Germar (l. c.).

**Alt.**—Quartz pseudomorphs occur near Klein-Voigtsberg.

**Ref.**—[1] Horhausen, nearly pure $MnCO_3$, with 1·14 FeO; another variety gave 72° 44′, Zs. Kr., **5**, 250,1880. The Lake Co., Colorado, variety in transparent rose-red rhombohedrons with faultless surface gave *rr′* = 73° 4′ 30″, E. S. D.; Mackintosh found in it 3·62 p. c. FeO, G. = 3·69. cf. Kunz, Am. J. Sc., **34**, 477, 1887. [2] See Mlr., Min., 588, 1852. [3] Peters, Kapnik, Jb. Min., 458, 1861, no angles. [4] Sandb., Oberneisen, Pogg., **88**, 491, 1853. [5] Weiss, Daaden, Zs. G. Ges., **31**, 801, 1879, also Sansoni, l. c.

**275. SMITHSONITE.** Calamine pt. Galmei pt. Zincum acido aëro mineralisatum *Bergm.*, Sciagr., 144, 1782, Opusc., **2**, 209, 1780 (from his own anal.). Zinkspath, Kohlengalmei, *Germ.* Carbonate of Zinc. Smithsonite *Beud.*, Tr., **2**, 354, 1832. Zinkspath, Kapnit (or Capnit), *Breith.*, Handb., 241, 236, 1841. Dry-bone *Miners.* Smitsonite *Ital.*

Rhombohedral. Axis $\dot{c}$ = 0·80633; $0001 \wedge 10\bar{1}1$ = 42° 57′ 20″ Wollaston[1].

**Forms**[2]: $a\ (11\bar{2}0, i\text{-}2)$ $M\ (40\bar{4}1, 4)$ $f\ (02\bar{2}1, -2)$ $s\ (05\bar{5}1, -5)$
$c\ (0001, O)$ $r\ (10\bar{1}1, R)$ $e\ (01\bar{1}2, -\frac{1}{2})$ $\chi\ (07\bar{7}2, -\frac{7}{2})$ $v\ (21\bar{3}1, 1^3)$

$cM$ = 74° 58′ $cs$ = 77° 52½ $ff'$ = 99° 27′ $ae$ = 68° 34′
$ce$ = 24° 58′ $rr'$ = *72° 20′ $\chi\chi'$ = 111° 46′ $vv'$ = 74° 41′
$cf$ = 61° 46′ $MM'$ = 113° 31½′ $ss'$ = 115° 42½′ $vv^{v}$ = 35° 19′
$c\chi$ = 72° 56½′ $ee'$ = 42° 53′ $ar$ = 53° 50′ $vv^{vi}$ = 49° 1½′

Rarely well crystallized; faces *r* generally curved and rough. Also reniform, botryoidal, or stalactitic, and in crystalline incrustations; also granular, and sometimes impalpable, occasionally earthy and friable.

Cleavable: *r* perfect. Fracture uneven to imperfectly conchoidal. Brittle. H. = 5. G. = 4·30–4·45; 4·45 Lévy; 4·42 Haid. Luster vitreous, inclining to pearly. Streak white. Color white, often grayish, greenish, brownish white, sometimes green, blue and brown. Subtransparent to translucent. Optically —.

**Comp.**—Zinc carbonate, $ZnCO_3$ = Carbon dioxide 35·2, zinc protoxide 64·8 = 100. Iron and manganese carbonates are often present, also calcium and magnesium carbonates in traces; rarely cadmium.

Indium has also been detected (Tennessee), by Tanner, Ch. News., **30**, 141, 1874. For analyses see 5th Ed., pp. 692, 693.

A bright yellow variety from Marion Co., Arkansas, gave H. N. Stokes (priv. contr.):

$CO_2$ 34·68 ZnO 64·12 CdO 0·63 FeO 0·14 CaO 0·38 Cu *tr* CdS 0·25 $SiO_2$ 0·06 = 100·26.

**Var.**—1. *Ordinary.* (*a*) *Crystallized;* (*b*) *botryoidal* and *stalactitic*, common, closely resembling similar forms of the silicate, calamine; (*c*) *granular* to *compact massive;* (*d*) *earthy*, impure, in nodular and cavernous masses, varying from grayish white to dark gray, brown, brownish red, brownish black, and often with drusy surfaces in the cavities; "dry-bone" of American miners, which also includes some calamine.

2. *Ferriferous.* Monheimite, Zinkeisenspath, Eisenzinkspath, *Germ.* Contains over 20 p. c. of iron carbonate; *Capnite* Breith., having *rr′* = 72° 53′, G. = 4·17 Breith.

3. *Manganiferous.* Contains over 5 p. c. of manganese carbonate; G. = 3·95–4·2.

4 *Cupriferous. Herrerite* of Del Rio. Apple-green, with rhombohedral cleavage; it was shown by Genth to belong here, Proc. Ac. Philad., **7**, 232.

**Pyr.**, etc.—In the closed tube loses carbon dioxide, and, if pure, is yellow while hot and white on cooling. B.B. infusible, moistened with cobalt solution and heated in O.F. gives a green color on cooling. With soda on charcoal gives zinc vapors, and coats the coal with the oxide, which is yellow while hot and white on cooling; this coating, moistened with cobalt solution, gives a green color after heating in O.F. Cadmiferous varieties, when treated with soda, give at first a deep yellow or brown coating before the zinc coating appears. With the fluxes some varieties react for iron, copper, and manganese. Soluble in hydrochloric acid with effervescence.

**Obs.**—Found both in veins and beds, especially in company with galena and sphalerite, also with copper and iron ores. It usually occurs in calcareous rocks, and is generally associated with calamine, and sometimes with limonite. It is often produced by the action upon zinc sulphide of carbonated waters.

Found at Nerchinsk in Siberia, one variety of a dark brown color, containing cadmium, another of a beautiful bright green; at Dognaczka in Hungary; Bleiberg and Raibel in Carinthia; Wiesloch in Baden, in Triassic limestone; Moresnet in Belgium; Altenberg, near Aix la Chapelle (Aachen), in concentric botryoidal groups. In the province of Santander, Spain, between the Bay of Biscay and the continuation of the Pyrenees range, at Puente Viesgo, the mountains being only four leagues from the coast; the smithsonite here occurs in Mountain limestone; in other places it is found in dolomite, probably Muschelkalk; it is in vertical lodes, found frequently in scalenohedrons as a pseudomorph after calcite. At Ciguenza, 5 miles E. of Santander, the lode varies in width from 1 to 2 meters to 1 inch; the mineral is drusy, cavernous; sphalerite is abundant, and changes into pure white smithsonite; the latter also occurs like chalcedony, in reniform and botryoidal masses; it sometimes contains galena and cerussite. In England, at Roughten Gill, Alston Moor, near Matlock, in the Mendip Hills, and elsewhere; in Scotland, at Leadhills; in Ireland, at Donegal. At Laurion, Greece, in great variety.

In the U. States, in *Conn.*, at Brookfield in very small quantities. In *N. Jersey*, at Mine Hill, near the Franklin Furnace, only pulverulent from decomposition of zincite. In *Penn.*, at Lancaster abundant, and often in fine druses of crystals, also sometimes pseudomorphous after dolomite; at the Perkiomen lead mine; at the Ueberroth mine, near Bethlehem, in scalenohedrons, also an earthy variety abundant as an ore. In *Wisconsin*, at Mineral Point, Shullsburg, etc., constituting pseudomorphs after sphalerite and calcite. In *Minnesota*, at Ewing's diggings, N.W. of Dubuque, etc. In south-western *Missouri* associated with sphalerite and calamine in St. François, Jefferson, Newton, Jasper counties; also with the lead ores in the central part of the state. In *Arkansas*, at Calamine, Lawrence Co.; in Marion Co., sometimes colored bright orange-yellow by greenockite (CdS) and then locally known as "turkey-fat ore."

Named after James Smithson (1754–1829), who founded the Smithsonian Institution in Washington. The name calamine is frequently used in England, cf. calamine, p. 549.

**Alt.**—Smithsonite changes through the action of alkaline silicates to the silicate calamine, or becomes incrusted with silica and forms quartz pseudomorphs. It is also sometimes replaced by limonite or göthite. The concretionary variety from Spain has a nucleus of calamine.

**Ref.**—[1] Cf. Breith., 72° 21½′, Handb., **1**, 241, 1841; Lévy also gives 72° 20′, Ann. Mines, **4**, 507, 1843. [2] See Lévy and Breith.; also Dx., Min., **2**, 150, 1874.

ORTHORHOMBIC ZINC CARBONATE(?) *Griffiths & Dreyfus*, Ch. News, **54**, 67, Aug. 6, 1886. From southwestern Siberia, associated with galena and barite in limestone. Described as occurring in right rhombic prisms, often showing twinning. H. = 5–6. G. = 4·629. Analysis of crystals:

$CO_2$ 35·21 ZnO 50·03 FeO 2·77 CdO 0·92 MnO 0·12 $SiO_2$ 5·62 $H_2O$ 5·33 = 100

It is called by the author isodimorphous with calcite and aragonite, but needs confirmation. (Pseudomorphous?)

**276. SPHÆROCOBALTITE.** *Weisbach*, Jb. Berg.-Hütt., 1877. Kobaltspath *Germ.*

Rhombohedral. In small spherical masses, with crystalline surface and concentric and radiated structure.

H. = 4. G. = 4·02–4·13. Luster vitreous. Color rose-red, altering superficially to velvet-black. Streak peachblossom-red.

**Comp.**—Cobalt protocarbonate, $CoCO_3$ = Carbon dioxide 37·1, cobalt protoxide 62·9 = 100.

**Anal.**—Winkler, l. c.

$CO_2$ 34·65 CoO 58·86 CaO 1·80 $Fe_2O_3$ 3·41 $H_2O$ 1·22 = 99·94

**Pyr., etc.**—B.B. in closed tube becomes black. Attacked slowly by cold acid; rapidly with effervescence when warmed. Reacts for cobalt with the fluxes.

**Obs.**—Occurs sparingly with roselite at Schneeberg, Saxony.

**Artif.**—An artificial rhombohedral cobalt carbonate is mentioned by Senarmont, Ann. Ch. Phys., **30**, 137, 1850.

## 2. Aragonite Group. $RCO_3$. Orthorhombic.

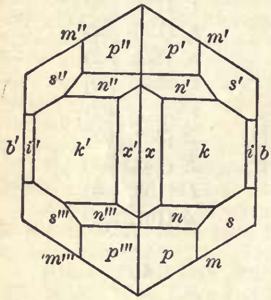
Twins[5]: tw. pl. *m*, commonly contact-twins, also penetration-twins, and as thin twinning lamellæ producing fine striations; twinning commonly repeated, thus producing pseudohexagonal forms, often of complex structure as revealed by etching or optical examination (cf. f. 8–12); a six-fold feather-like striation on *c* (resembling the markings on f. 6, p. 284) common with twins from Sicily. Crystals often acicular, and characterized by the presence of acute domes or pyramids. Also globular, reniform, and coralloidal shapes; sometimes columnar, composed of straight or divergent fibers; also stalactitic; incrusting.

13.



Cleavage: *b* distinct; also *m*; *k* (011) imperfect. Fracture subconchoidal. Brittle. H. = 3·5–4. G. = 2·93–2·95; 2·99 tarnowitzite. Luster vitreous, inclining to resinous on surfaces of fracture. Color white; also gray, yellow, green, and violet; streak uncolored. Transparent to translucent. Optically –. Ax. pl. ∥ *a*. Bx ⊥ *c*. Dispersion $\rho < \upsilon$ small. Refractive indices (Rudberg[6]) and axial angles (Kirchhoff[7]) for the Fraunhofer lines:

**Comp.**—Calcium carbonate, $CaCO_3$ = Carbon dioxide 44·0, lime 56·0 = 100. Some varieties contain a little strontium, others lead, and rarely zinc.

**Var.**—1. *Ordinary.* (*a*) Crystallized in simple or compound crystals, the latter much the most common; often in radiating groups of acicular crystals. G. = 2·927 Biot; 2·931 Haid.; 2·932 Kamsdorf, Schmid: 2·945–2·947 small crystals, Beud. (*b*) Columnar; also fine fibrous with silky luster. (*c*) Massive.

2. *Scaly massive.* Snow-white (*Schaumkalk*); G. = 2·984; from Wiederstadt, a pseudomorph after gypsum.

3. *Stalactitic* or *stalagmitic.* Either compact or fibrous in structure, as with calcite; *Sprudelstein* is stalactitic from Carlsbad.

4. *Coralloidal.* In groupings of delicate interlacing and coalescing stems, of a snow-white color, and looking a little like coral; often called *Flos ferri* (Eisenblüthe *Germ.*).

5. *Tarnowitzite.* A kind containing lead carbonate, from Tarnowitz in Silesia; with G. = 2·99. Böttger found 3·89 p. c. $PbCO_3$, Pogg., **47**, 497, 1839, and Herde 8·56, Zs. Kr. **9**, 199, 1884. Traube found in an aragonite from Tarnowitz 0·80, 0·46 p. c. $PbCO_3$ and 1·38, 1·06 $ZnCO_3$; the true tarnowitzite, however, gave him 6·64 $PbCO_3$ and only a trace of zinc, Zs. Kr., **15**, 410, 1889.

A variety from Wythe Co., Va., gave Dunnington, 7·29 $PbCO_3$, Proc. Am. Ch. Soc., **2**, 14, 1878. Collie found in a "plumbo-aragonite" from Leadhills, 0·8–1·3 p. c. $PbCO_3$, G. = 2·9, J. Ch. Soc., **55**, 95, 1889.

*Mossottite* is a light green, columnar, radiated variety, from the Lias of Gerfalco, in Tuscany, containing nearly 7 p. c. of strontium carbonate and a trace of copper; G. = 2·884. *Oserskite* is columnar aragonite from Nerchinsk, Siberia; G. = 2·854–2·855.

**Pyr., etc.**—B.B. whitens and falls to pieces, and sometimes, when containing strontia, imparts a more intensely red color to the flame than lime; otherwise reacts like calcite.

**Obs.**—The most common repositories of aragonite are beds of gypsum, beds of iron ore (where it occurs in coralloidal forms, and is denominated *flos-ferri*, "*flower of iron*"), basalt, and trap rock; occasionally it occurs in lavas. It is often associated with copper and iron pyrites, galena, and malachite. It is forming at an old mine in Monte Vasa, Italy, at a temperature below the boiling point of water; also at a temperature of 30° C. in the Eureka mine, Nevada, the formation going on rapidly, a rate of $\frac{5}{16}$ inch in three weeks being noted (J. S. Curtis, U. S. G. Surv., Mon., **7**, 57, 1884). It constitutes the pearly layer of shells. Minute pointed crystals occur in drusy cavities in the sinter of the thermal springs of Baden.

First discovered in Aragon, Spain, at Molina and Valencia, near Migranilla, in six-sided prisms, with gypsum, embedded in a ferruginous clay. Since found at Bilin in Bohemia, in a vein traversing basalt in fine prisms; at Sasbach, Kaiserstuhl, Baden; at Baumgarten and Tarnowitz in Silesia; at Leogang in Salzburg, Austria; in Waltsch, Bohemia; Herrengrund, Hungary; Dognaczka; with sulphur in Sicily in fine prisms. The *flos-ferri* variety is found in great perfection in the Styrian mines, coating cavities and even caves of considerable extent, and associated with siderite. At Dufton, a silky, fibrous variety, called *satin spar*, occurs traversing shale in thin veins, generally associated with pyrite. In Buckinghamshire, Devonshire, etc., it occurs in stalactitic forms in caverns, and of snowy whiteness at Leadhills in Lanarkshire. At Alston Moor, fine tapering crystals. A banded and fibrous form ("alabaster") of a delicate blue at Caterno, Chili.

Aragonite in fibrous crusts and other forms occurs in serpentine at Hoboken, N. J. (it has been called magnesite). Coralloidal aragonite occurs sparingly at Lockport, N. Y., coating gypsum in geodes; at Edenville, N. Y., lining cavities of arsenopyrite and pharmacosiderite; at the Parish ore bed, Rossie, N. Y.; at Haddam, Conn., in thin seams between layers of gneiss; at New Garden, in Chester Co., Penn.; at Wood's Mine, Lancaster Co., Penn.; at Warsaw, Ill., lining geodes; Mine-la-Motte, Mo., in crystals; on the north boundary of the Creek nation, 16 m. from the crossing of the Arkansas, in hexagonal crystals nearly $\frac{1}{2}$ in. through. *Flos-ferri* in the Organ Mts., New Mexico.

**Alt.**—Aragonite may undergo similar changes with calcite. Pseudomorphs of copper after aragonite occur at Corocoro, Bolivia (see p. 22).

A change by paramorphism to calcite is not uncommon; the reverse change, yielding pseudomorphs of aragonite after calcite, is rare (cf. Bauer, Jb. Min., **1**, 12, 1890). The change into calcite can be caused by elevation of temperature, as shown by the loss in specific gravity (Rose), and in the change to uniaxial character (Klein); cf. also Mgg. Jb., **1**, 62, 1886.

**Ref.**—[1] Bilin, Min. Russl., **6**, 261, 1875. The prismatic angle *mm'''* increases with rise of temperature, 2′ 46″ for 100° and *kk'* diminishes 5′ 29″, Mitsch., Pogg., **10**, 144, 1827. Beckenkamp makes the crystals hemimorphic both in the direction of the $\bar{b}$ and $\dot{c}$ axes, and hence apparent simple crystals would become twins with *b* or *c* as twinning planes, Zs. Kr., **14**, 375, 1888

[2] See Mlr., Min., 567, 1852; Schrauf, Atlas XXI–XXIII, 1872, also Ber. Ak. Wien, **62** (2), 734, 1870, **65** (1), 250, 1872; Dx., Min., **2**, 86, 1874; Zeph., Ber. Ak. Wien, **71** (1), 253, 1875, new planes, list, authorities, etc., he adds several vicinal prismatic planes; Gdt., Index, **1**, 239, 1886. On the tapering forms with high indices, see Websky, tarnowitzite, Zs. G Ges., **9**, 737, 1857; Schmid, Pogg., **126**, 147, 1865; Zeph., Langer, Zs. Kr., **9**, 196, 1885. [3] Langer, l. c. **278. BROMLITE.** Barytocalcite *J. F. W. Johnston*, Phil. Mag., **6**, 1, 1835, **10**, 373, 1837. Bicalcareo-carbonate of Barytes (from a wrong anal.) *Thomson*. Rec. Gen. Sc., **1**, 373, 1835. Bromlite *Thomson*, Phil. Mag., **11**, 45, 48, 1837. Alstonite *Breith.*, Handb., **2**, 255, 1841.

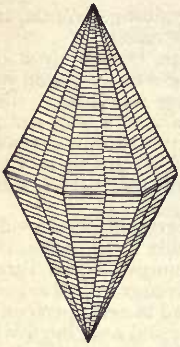
Orthorhombic; form near witherite. The crystals are dihexahedral pyramids formed by complex twinning[1]; the faces are horizontally striated, and also divided vertically by a medial twinning line (f. 1, 2). Pyramidal angles 57° 30′ adjacent, 38° basal, Dx.

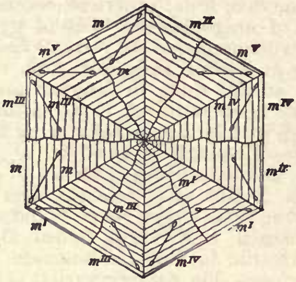
Cleavage: *m* imperfect. Fracture uneven. H. = 4–4·5. G. = 3·718, Th.; 3·706, J. Luster vitreous. Colorless, snow-white, grayish, pale cream-color, pink.

Translucent. Optically −. Ax. pl. ‖ *a*. Bx ⊥ *c*. Dispersion nearly zero. Axial angles[1]:

1.



2.



Des Cloizeaux.

$2E_r = 9° 50'$ at 17° C.,
$= 11° 10'$ at 141·5° C., Dx.

**Comp.**—An isomorphous compound of the carbonates of barium and calcium, $(Ba,Ca)CO_3$; ratio of Ba : Ca = 1 : 1 (anal. 1, 2), also 3 : 4 (anal. 3), 1 : 2 (anal. 4). $BaCO_3.CaCO_3$ = Barium carbonate 66·3, calcium carbonate 37·7, or Carbon dioxide 29·6, baryta 51·5, lime 18·9 = 100. Strontium carbonate is given in some analyses.

**Anal.**—1–4, Becker, Zs. Kr., **12**, 222, 1886. Cf. also 5th Ed., p. 698.

| | | $CO_2$ | BaO | CaO | | |
|---|---|---|---|---|---|---|
| 1. Alston Moor | $\frac{3}{3}$ | 29·65 | 50·97 | 19·83 | insol. 0·25 | = 100·70 |
| 2. " " | $\frac{3}{3}$ | 29·52 | 51·45 | 19·89 | MnO 0·20 | = 101·06 |
| 3. " " | $\frac{3}{3}$ | 31·71 | 44·69 | 23·40 | MnO 0·29 | = 100·09 |
| 4. " " | $\frac{2}{2}$ | 32·21 | 37·41 | 29·06 | MnO 0·30 | = 98·98 |

**Pyr., etc.**—Same as for barytocalcite, p. 289.

**Obs.**—Found at the lead mine of Fallowfield, near Hexham in Northumberland, with witherite, and at Bromley Hill near Alston in Cumberland, in veins with galena, whence the name *Bromlite*, given by Thomson. Most English mineralogical authors have set aside Thomson's name, although the earliest and of British origin, for Breithaupt's. There appears to be no sufficient reason for this.

**Ref.**—[1] Min., **2**, 79, 1874.

**279. WITHERITE.** Terra ponderosa aerata *Withering*, Trl. Bergm. Sciagr., 29, 1783, Phil. Trans., 293, 1784. Witherit *Wern.*, Bergm. J., **2**, 225, 1790. Aerated Barytes *Watt*, Mem. Manchester Soc., **3**, 599, 1790. Barolite *Kirwan*, Min., **1**, 134, 1794. Kohlensaurer Baryt *Germ.* Baryte carbonatée *Fr.*

Orthorhombic. Axes $\breve{a} : \bar{b} : \dot{c} = 0·6032 : 1 : 0·7302$ Des Cloizeaux.
$100 \wedge 110 = 31° 6'$, $001 \wedge 101 = 50° 26\frac{1}{2}'$, $001 \wedge 011 = 36° 8\frac{1}{4}'$.

**Forms:** *c* (001, *O*) *g* (130, *i*-$\breve{3}$) *x* (012, $\frac{1}{2}$-$\breve{i}$) *i* (021, 2-$\breve{i}$) *n* (041, 4-$\breve{i}$)

Section ‖ *c*, Dx.

surfaces of fracture. Color white, often yellowish, or grayish. Streak white. Subtransparent to translucent. Optically −. Ax. pl. ∥ *b*. Bx ⊥ *c*.

$$2E_r = 26° 30' \text{ at } 17° \text{ C.}, \quad = 26° 24' \text{ at } 121° \text{ C., Dx.}$$

**Comp.**—Barium carbonate, $BaCO_3$ = Carbon dioxide 22·3, baryta 77·7 = 100.

Thomson's *Sulphato-carbonate of Baryta* is witherite incrusted by barite, as shown by Heddle.

**Pyr., etc.**—B.B. fuses at 2 to a bead, coloring the flame yellowish green; after fusion reacts alkaline. B.B. on charcoal with soda fuses easily, and is absorbed by the coal. Soluble in dilute hydrochloric acid; this solution, even when very much diluted, gives with sulphuric acid a white precipitate which is insoluble in acids.

**Obs.**—Occurs at Alston Moor in Cumberland, associated with galena, in veins traversing the coal formation; at Fallowfield near Hexham in Northumberland, in large quantities, also in splendid crystals, sometimes transparent, and occasionally 6 in. long; at Anglezarke in Lancashire, a fibrous variety; at Arkendale in Yorkshire; near St. Asaph in Flintshire; Tarnowitz in Silesia; Szlana, Hungary; Leogang in Salzburg; Peggau in Styria; Zméov in the Altai; some places in Sicily; the mine of Arqueros, near Coquimbo, Chili; L. Etang Island. Near Lexington, Kentucky, with barite. In a silver-bearing vein near Rabbit Mt., Thunder Bay, L. Superior.

**Alt.**—Witherite is altered to barite through the action of calcium sulphate in solution at the ordinary temperature, or by the action of other sulphates in solution, or of water containing sulphuric acid.

**Artif.**—Formed from fusion of alkaline chlorides by Bourgeois, Bull. Soc. Min., **5**, 111, 1882.

**280. STRONTIANITE.** Strontianit *Sulzer*, Lichtenberg's Mag., **7**, 3, 68, Bergm. J., **1**, 5, 433, 1791. Strontian *Wern.* Strontianit. Twins: tw. pl. *m* very common, usually contact-, rarely penetration-twins, also repeated, trillings, fourlings, and again polysynthetic giving inclosed tw. lamellæ. Crystals often acicular or acute spear-shaped, like aragonite, from the presence of acute pyramids and brachydomes; forms *hhl* and 0·2*h*·*l* often present together (f. 2) giving a pseudohexagonal aspect. Also in columnar globular forms; fibrous and granular.

Cleavage: *m* nearly perfect; *b* in traces. Fracture uneven. Brittle. H. = 3·5–4. G. = 3·680–3·714 Dmr. Luster vitreous; inclining to resinous on uneven faces of fracture. Color pale asparagus-green, apple-green; also white, gray, yellow, and yellowish brown. Streak white. Transparent to translucent. Optically −. Ax. pl. ∥ *b*. Bx ⊥ *c*. Dispersion $\rho < v$ small.

$$2E_r = 12^\circ\, 17' \qquad 2E_{bl} = 12^\circ\, 24'.$$

**Comp.**—Strontium carbonate, $SrCO_3$ = Carbon dioxide 29·9, strontia 70·1 = 100. A little calcium is sometimes present.

Cf. analyses, 5th Ed., p. 699, Macadam obtained for selected strontianite from Strontian: $SrCO_3$ 94·50, $BaCO_3$ 0·21, $CaCO_3$ 4·82 = 99·53. The white massive form gave, with 56·60 $SrCO_3$ and 6·81 $CaCO_3$, etc., also 21·25 $SrSO_4$, 10·01 $BaSO_4$ and 3·64 $CaSO_4$. Min. Mag., **6**, 173, 1885.

Heddle describes a variety from Sutherland with 8·53 CaO, G. = 3·447, Min. Mag., **5**, 175, 1883. Vrba (l. c.) gives (anal. by Kovář) 6·37 $CaCO_3$ and G. = 3·69, for the strontianite from Altahlen.

Thomson obtained in his *emmonite* "from Massachusetts": $SrCO_3$ 82·69, $CaCO_3$ 12·50, $Fe_2O_3$ 1·00, zeolite 3·79 = 99·98. G. = 2·946. Named for Prof. Emmons. Cathrein gives for a similar mineral (*calciostrontianite*) from Brixlegg, Tyrol: $SrCO_3$ 86·89, $CaCO_3$ 13·14 = 100·03. It occurs in highly modified crystals, f. 2, Zs. Kr., **14**, 366, 1888.

Traill's *stromnite* is pronounced a mixture by Greg and Lettsom. It is from near Stromness, on Pomona, one of the Orkneys.

**Pyr., etc.**—B.B. swells up, throws out minute sprouts, fuses only on the thin edges, and colors the flame strontia-red; the assay reacts alkaline after ignition. Moistened with hydrochloric acid and treated either B.B. or in the naked lamp gives an intense red color. With soda on charcoal the pure mineral fuses to a clear glass, and is entirely absorbed by the coal; if lime or iron be present they are separated and remain on the surface of the coal. Soluble in hydrochloric acid; the dilute solution when treated with sulphuric acid gives a white precipitate.

**Obs.**—Occurs at Strontian in Argyllshire, in veins traversing gneiss, along with galena and barite, in acicular diverging and fibrous groups, rarely in perfect crystals; in Yorkshire, England; Giant's Causeway, Ireland; Clausthal in the Harz; Bräunsdorf, near Freiberg, Saxony. Leogang in Salzburg; on the Grosskogel, near Brixlegg, Tyrol (*calciostrontianite*); massive and in fine crystals in the neighborhood of Hamm, Westphalia; at the Wilhelmine mine near Altahlen, Münster, Westphalia, in large crystals up to 20 mm. in height and 16 mm. in breadth.

In the U. States it occurs at Schoharie, N. Y., in granular and columnar masses, and also in crystals, forming nests or geodes, often large, in the hydraulic limestone, associated with barite, pyrite, and calcite. At Clinton, Oneida Co. At Muscalonge Lake a massive and fibrous variety, of a white or greenish white color, is sometimes the matrix of fluorite. Chaumont Bay and Theresa, in Jefferson Co., N. Y., Mifflin Co., Penn., are other localities. Sparingly on St. Helen's Is., near Montreal.

**Alt.**—Strontianite is altered to celestite in the same way as witherite to barite.

**Artif.**—Formed by fusion in alkaline chlorides in elongated prismatic crystals, optically negative, Bourgeois Bull. Soc. Min., **5**, 111, 1882.

**Ref.**—[1] Credited by Zippe and by Hausmann. Strontianite is hemimorphic according to Beckenkamp, cf. aragonite. [2] Cf. Mlr., Min., 569, 1852. [3] Hbg., Clausthal, Min. Not., **9**, 41, 1870. Twins[6]: tw. pl. *m*, very common, contact- and penetration-twins, often repeated yielding six-rayed stellate groups; also less common tw. pl. *r* (130). Simple crystals often tabular ∥ *b*, prismatic ∥ *ă*; also pyramidal. Brachydome faces and *b* usually horizontally striated, also *p* often striated ∥ edge *m*/*p* or *i*/*p*. Crystals grouped in clusters, and aggregates. Rarely fibrous, often granular massive and compact; earthy. Sometimes stalactitic.

Cleavage: *m* and *i* (021) distinct; *b* and *x* (012) in traces. Fracture conchoidal. Very brittle. H. = 3–3·5. G. = 6·46–6·574 Dmr. Luster adamantine, inclining to vitreous, resinous, or pearly; sometimes submetallic, if the colors are dark, from a superficial change. Color white, gray, grayish black, sometimes tinged blue or green by some of the salts of copper; streak uncolored. Transparent to subtranslucent. Optically −. Ax. pl. ∥ *b*. Bx ⊥ *c*. Dispersion $\rho > v$ large. Indices and axial angles, Schrauf[9]:

| | $\alpha$ | $\beta$ | $\gamma$ | | 2V | 2E |
|---|---|---|---|---|---|---|
| Line B | 1·79148 | 2·05954 | 2·06131 | ∴ | 8° 22′ | 17° 16½′ |
| " D | 1·80368 | 2·07628 | 2·07803 | ∴ | 8° 14′ | 17° 8′ |
| " E | 1·81641 | 2·09194 | 2·09344 | ∴ | 7° 35′ | 15° 55′ |

Also $2E_r = 18^\circ\ 22'$ at 12° C., 20° 20′ at 71·5° C., 22° 2′ at 95·5° C., Dx[9].

**Comp.**—Lead carbonate, $PbCO_3$ = Carbon dioxide 16·5, lead oxide 83·5 = 100.

Kersten obtained for the *iglesiasite* (Schw. J., **65**, 365, 1832): $PbCO_3$ 92·10, $ZnCO_3$ 7·02 = 99·12. G. = 5·9.

**Pyr., etc.**—In the closed tube decrepitates, loses carbon dioxide, turns first yellow, and at a higher temperature dark red, but becomes again yellow on cooling. B.B. on charcoal fuses very easily, and in R.F. yields metallic lead. Soluble in dilute nitric acid with effervescence.

**Obs.**—Occurs in connection with other lead minerals, and is formed from galena, which, as it passes to a sulphate, may be changed to carbonate by means of solutions of calcium bicarbonate. It is found at Johanngeorgenstadt in beautiful crystals; at Berezov in Siberia; in the Altai; at Nerchinsk and in fine crystals in the Transbaikal at the Kadainsk, Taininsk, and other mines; Monte Poni, Sardinia; Pajsberg, Sweden; near Bonn on the Rhine; Friedrichssegen near Braubach, Nassau; Badenweiler, Baden; at Clausthal in the Harz, and at Andreasberg (Bleiglimmer); at Bleiberg in Carinthia; at Mies and Příbram in Bohemia; at Rezbanya and Telekes, Hungary; Laurion, Greece; in England, in Cornwall, in the mine of St. Minvers; delicate crystals 10 in. long were formerly found near St. Austell and elsewhere; at E. Tamar mine, Devonshire; near Matlock and Wirksworth, Derbyshire; in Cardiganshire, Wales; at Leadhills and Wanlockhead, Scotland, formerly in fine crystals; in Wicklow, Ireland, magnificent, sometimes in heart-shaped twins. In pseudomorphs after anglesite and leadhillite, at Leadhills.

Found in *Mass.*, sparingly at the Southampton lead mine. In *Penn.*, at Phenixville, in fine crystals, often large; also at Perkiomen. In *N. York*, at the Rossie lead mine, rare. In Frederick Co., *Maryland*, with anglesite at a lead mine, 2½ miles S. W. of Union Bridge. In *Virginia*, good crystals at Austin's mines, Wythe Co. In *N. Carolina*, in King's mine, Davidson Co. At Valle's diggings, Mo., but seldom crystallized; in good crystals at Franklin Furnace, Washington Co; in Wisconsin and other lead mines of the northwestern States, rarely in crystals; at Hazelgreen, crystals coating galena; near the Blue Mounds, Wis., at Brigham's diggings, in stalactites. In *Colorado*, at Leadville, and elsewhere. In *Utah*, at the Flagstaff mine in very thin delicate tables. In *Arizona*, at the Flux mine, Pima Co., in large crystalline masses up to 60 lbs. in weight; in crystals at the Red Cloud mine, Yuma Co.

*Bleierde* occurs in opaque earthy nodules at Tarnowitz, Kall in the Eifel, and elsewhere. *Bleischwärze*, a black carbonaceous lead carbonate, occurs at Tarnowitz, Mies, Badenweiler, etc.

**Alt.**—Cerussite occurs altered to pyromorphite, galena, minium.

Pseudomorphs after galena, phosgenite, anglesite, leadhillite, linarite, etc., have been noted.

**Artif.**—Cf. Riban, C. R., **93**, 1026, 1881.

Observed as a recent formation at Pompeii; also similarly at Laurium, Greece.

**Ref.**—[1] Min. Russl., **6**, 100, 1870. [2] For lists of planes, authorities, etc., cf. Mlr., Min., 565, 1852; Lang, Vh. Min. ## 3. Barytocalcite Group. Monoclinic.

### 282. BARYTOCALCITE. *Brooke*, Ann. Phil., 8, 114, 1824.

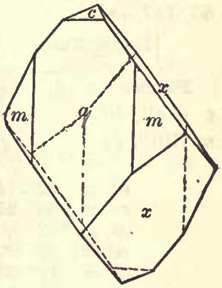
Monoclinic. Axes $\grave{a} : \bar{b} : \grave{c} = 0·77171 : 1 : 0·62545$; $\beta = 73° 52' = 001 \wedge 100$ Brooke[1].

$100 \wedge 110 = 36° 33'$, $001 \wedge 101 = {}^*32° 26'$, $001 \wedge 011 = 30° 59\frac{5}{6}'$.

**Forms**[1]:
*a* (100, *i*-*ī*)
*c* (001, *O*)
*m* (110, *I*)
*g* (120, *i*-2)
*o* (101, = 1-*ī*)
*x* ($\bar{1}$21, 2-$\grave{2}$)
*y* ($\bar{1}$51, 5-$\grave{5}$)
*ρ* ($\bar{1}$61, 6-$\grave{6}$)

$mm''' = {}^*73° 6'$ $a'x = 70° 54'$ $cm = {}^*77° 6'$ $yy' = 139° 50'$
$gg' = 68° 0'$ $cx = 61° 35'$ $xx' = 95° 8\frac{1}{2}'$ $\rho\rho' = 146° 7'$
$ao = 41° 26'$

Crystals prismatic by extension of *x*, *y*. Faces *a* vertically striated; also *x*, *y*, *ρ* ‖ each other. Also massive.



Cleavage: *m* perfect; *c* less so. Fracture uneven to subconchoidal. Brittle. H. = 4. G. = 3·64–3·66. Luster vitreous, inclining to resinous. Color white, grayish, greenish, or yellowish. Streak white. Transparent to translucent. Optically −. Ax. pl. and $Bx_o \perp b$. $Bx_a \wedge \grave{c} = +64° 22'$. Dispersion $\rho > v$, small; horizontal nearly zero. Axial angles for two sections Dx.:

$$2E_{.} = 23° 15', \quad 3E_{bl} = 22° 47';$$

also $2E_r = 24° 53'$ at 17° and 25° 38′ at 170·8° C.

**Comp.**—Carbonate of barium and calcium, $BaCO_3.CaCO_3$ = Barium carbonate 66·3, calcium carbonate 33·7 = 100, or Carbon dioxide 29·6, baryta 51·5, lime 18·9 = 100. Cf. bromlite, p. 283.

**Anal.**—1–3 Becker, Zs. Kr., **12**, 222, 1886. Also 5th Ed., p. 702.

| | $CO_2$ | BaO | CaO | MnO | |
|---|---|---|---|---|---|
| 1. | $\frac{3}{3}$ 29·52 | 50·09 | 19·77 | 0·35 | = 99·73 |
| 2. | $\frac{4}{4}$ 29·44 | 50·36 | 19·22 | 0·25 | insol. 0·30 = 99·57 |
| 3. | $\frac{3}{3}$ 29·39 | 51·59 | 18·61 | 0·35 | insol. 0·28 = 100·22 |

**Pyr., etc.**—B.B. colors the flame yellowish green, and at a high temperature fuses on the thin edges and assumes a pale green color (barium manganate, Plattner); the assay reacts alkaline after ignition. With the fluxes reacts for manganese. With soda on charcoal the lime is separated as an infusible mass, while the remainder is absorbed by the coal. Soluble in dilute hydrochloric acid.

**Obs.**—Occurs at Alston-Moor in Cumberland, in attached crystals and massive, in the Subcarboniferous or Mountain limestone with barite and fluorite. Crystals 2 in. long have been obtained.

**Ref.**—[1] L. c. Cf. also Haid., Pogg., **5**, 160, 1825. Dx., Ann. Ch. Phys., **13**, 425, 1845; also Min., **2**, 80, 1874. With Mlr. (Min., 574, 1852), $x = 110$, $m = 111$ (*s*), $o = 001$.

**283. BISMUTOSPHÄRITE.** Arsenikwismuth *Werner*, Min. Syst., 56, 1817. Luftsaures Wismuth *Beyer*, 1805. Bismutosphärit *Weisbach*, Jb. Berg.-Hütt., 1877.

In spherical forms with concentric and fine fibrous, radiated structure; also pseudomorphous after stibnite.

H. = 3–3·5. G. = 7·30 Weisb.; 7·42 Wells. Color bright yellow to dark gray or blackish brown.

**Comp.**—$Bi_2CO_5$ or $Bi_2(CO_3)_3.2Bi_2O_3$ = Carbon dioxide 8·7, bismuth trioxide 91·3 = 100.

**Anal.**—1, Winkler (quoted by Weisb.) l. c. 2, Id., Jb. Min., **2**, 254, 1882 (cf. Frenzel, ib., 801 1873). 3, H. L. Wells, Am. J. Sc., **34**, 271, 1887. 4, 5, E. S. Sperry, ibid. 6, Wells, l. c.

|---|---|---|---|---|---|
| 1. | Schneeberg | G. = 7·30 | 8·97 | 88·58 | quartz 0·28, loss 2·17 = 100 |
| 2. | Guanajuato | G. = 7·64 | 8·29 | 91·68 | $SiO_2$,$Fe_2O_3$ *tr.* = 99·97 |
| 3. | Willimantic | G. = 7·42 | 8·03 | 91·64 | $H_2O$ 0·47, $SO_3$ 0·34, insol. 0·08, $Fe_2O_3$ *tr.* = 100·56 |
| 4. | " | | 8·01 | 92·07 | $H_2O$ 0·90 = 100·98 |
| 5. | " | | 7·92 | 92·05 | $H_2O$ 0·54 = 100·51 |
| 6. | Portland | | 7·54 | 89·03 | $H_2O$ 0·94, $Fe_2O_3$, CuO, insol. 2·79 = 100·30 |

**Pyr.**—Gives no water, or only a minute amount, in the closed tube, fusing easily. Bismuth coating on charcoal. Dissolves entirely with effervescence in nitric acid.

**Obs.**—At Schneeberg, Saxony (Werner's *arsenikwismuth*, Weisb.) with quartz on brown spar, which last carries native bismuth and smaltite. At Guanajuato, Mexico, pseudomorphous. Also sparingly at Willimantic and Portland, Conn., as a result of the alteration of bismuthinite in a feldspar vein in gneiss. It retains the structure of the origiual mineral, but in cavities minute crystals in scales are noted which are probably the same mineral.

---

## 4. Parisite Group. Hexagonal.

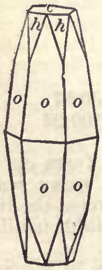
**284. PARISITE.** Musite *Medici-Spada*, 1835. Parisit *Medici-Spada*, Bunsen, Lieb. Ann., **53**, 147, 1845.

Hexagonal. Axis $\dot{c}$ = 3·2891; 0001 ∧ 10$\bar{1}$1 = 75° 15′ Des Cloizeaux[1].

| **Forms**[1]: | | | | |
|---|---|---|---|---|
| | *q* (10$\bar{1}$2, $\frac{1}{2}$) | *o* (20$\bar{2}$1, 2) | *f* (11$\bar{2}$4, $\frac{1}{2}$-2) | *k* (22$\bar{4}$3, $\frac{4}{3}$-2) |
| *c* (0001, *O*) | *r* (20$\bar{2}$3, $\frac{2}{3}$) | *d* (11$\bar{2}$8, $\frac{1}{4}$-2) | *g* (11$\bar{2}$3, $\frac{2}{3}$-2) | *s* (11$\bar{2}$1, 2-2) |
| *m* (10$\bar{1}$0, *I*) | *p* (10$\bar{1}$1, 1) | *e* (11$\bar{2}$6, $\frac{1}{3}$-2) | *h* (11$\bar{2}$2, 1-2) | *x* (63$\bar{9}$5, $\frac{9}{5}$-$\frac{3}{2}$) |

| | | | |
|---|---|---|---|
| *cq* = 62° 14′ | *cg* = 65° 29′ | *pp′* = 57° 50′ | *kk′* = 58° 21′ |
| *cr* = 68° 27′ | *ch* = 73° 5′ | *oo′* = 59° 26′ | *ss′* = 59° 15′ |
| *co* = *82° 30′ | *ck* = 77° 9′ | *dd′* = 37° 2′ | *xx′* = 21° 29′ |
| *cd* = 39° 26′ | *cs* = 81° 21′ | *ff′* = 50° 35′ | *xx*$^{x1}$ = 37° 41′ |
| *ce* = 47° 38′ | *qq′* = 52° 31′ | *hh′* = 57° 9½′ | *cx* = 80° 35′ |
| *cf* = 58° 42′ | *rr′* = 55° 25½′ | | |

Crystals usually acute double hexagonal pyramids terminated by *c*; *m* rare. Faces *c* slightly uneven; planes in zone *cs* horizontally striated, of zone *cp* horizontally channeled.



Muso, Vrba[1].

Cleavage: *c* very perfect. Fracture small conchoidal. Brittle. H. = 4·5. G. = 4·358 Dmr.; 4·364 Vrba. Luster vitreous; on *c* pearly or resinous. Color brownish yellow; streak yellowish white. Translucent; transparent in thin sections. Optically +. Double refraction strong. Indices: $\omega$ = 1·569, $\epsilon$ = 1·670, Sen.[2]

**Comp.**—A fluocarbonate of the cerium metals, composition perhaps $(CaF)(CeF)Ce(CO_3)_3$ Groth, with the cerium replaced in part by didymium and lanthanum.

**Anal.**—Damour & Deville, C. R., **59**, 270, 1864 (as given by Rg., Min. Ch., 251, 1875). Also Bunsen, see 5th Ed., p. 703.

| | $CO_2$ | Ce | La | Di | Ca | F | O |
|---|---|---|---|---|---|---|---|
| G. = 4·358 | 23·48 | 37·75 | 6·86 | 8·21 | 7·22 | 5·55 | [10·93] |

**Pyr., etc.**—In the closed tube yields no water, but gives off carbon dioxide and becomes lighter in color. B.B. glows and is infusible. With fused salt of phosphorus in the open tube gives B.B. the reaction for fluorine. With borax and salt of phosphorus in the platinum loop gives a glass, yellow while hot and colorless on cooling. Dissolves slowly in hydrochloric acid with effervescence.

**Obs.**—From the emerald mines of the Muso valley, U. S. Colombia, where it was discovered by J. J. Paris, the proprietor of the mine, after whom it was named, and from which place it was sent in 1835 to Medici-Spada, of Rome, by Col. Acosta. The earlier name *Musite* (sometimes written *Mussite*, the name of the valley being written both Muso and Musso, as well as Muzo) is objectionable, because of the use of the name *Mussite* for a variety of pyroxene.

A mineral is probably to be referred here (Brögger, Zs. Kr., **16**, 650, 1890), which occurs very sparingly in hexagonal tabular crystals, sometimes in rosettes, with weibyeïte at the eudidymite locality on Ober-Arö, Langesundfiord, Norway.

**Ref.**—[1] Min., **2**, 162, 1874. Vrba gives, *ch* = 73° 26′ 50″ and $\dot{c}$ = 3·3646, Ber. Böhm. Ges., 647, 1886, and Zs. Kr., **15**, 210, 1888. [2] Quoted by Dx.

KISCHTIMITE. Kischtim-Parisit *T. Karavayev*, Bull. Ac. St. Pet., **4**, 401, 1861, J. pr. Ch., **85**, 442, 1862. Kk., Min. Russl., **4**, 40, 1862. Kischtimite *G. J. Brush*, Am. J. Sc., **35**, 427, 1863. Kyshtymo-parisite.

Massive. H. = 4·5. G. = 4·784. Luster between greasy and vitreous. Color dark brownish yellow. Streak much lighter than color. In small pieces translucent.

A fluocarbonate of the cerium metals near parisite. Analysis: Karavayev:

| | $CO_2$ | La | Ce | F | O | $H_2O$ | |
|---|---|---|---|---|---|---|---|
| ⅔ | 17·19 | 36·56 | 27·81 | 6·35 | [9 89] | 2·20 | = 100 |

From the gold washings of the Barsovka river, in the district of Kyshtymsk, Ural.

**285. BASTNÄSITE.** Basiskfluorcerium *Hisinger*, Öfv. Ak. Stockh., 189, 1838. Bastnäsite *Huot*, Min., **1**, 296, 1841. Hamartite *A. E. Nordenskiöld*, Öfv. Ak. Stockh., **25**, 399, 1868.

Basisk flussspatssyradt Cerium *Berz.*, Afh., **6**, 64, 1818. Basisches Fluorcerium. Basic fluocerine. Basicerine *Beud.* Fluocerine *Hausm.*, 1847. Hydrofluocerite.

Massive, and in hexagonal prisms[1], pseudomorphous after tysonite.

H. = 4–4·5. G. = 4·93 Nd.; 5·19 Allen. Luster vitreous to greasy. Color wax-yellow to reddish brown. Streak light yellowish gray.

**Comp.**—A fluocarbonate of the cerium metals $(RF)CO_3$ or $(Ce,La,Di)_2C_3O_9.(Ce,La,Di)F_3$.

**Anal.**—1, Nd., l. c.; he also recalculates Hisinger's results and shows that they correspond to his, allowing for the $CO_2$, which was overlooked. 2, Allen and Comstock, Am. J. Sc., **19**, 390, 1880.

| | | $CO_2$ | $Ce_2O_3$ | $(La,Di)_2O_3$ | F | |
|---|---|---|---|---|---|---|
| 1. | G. = 4·93 | 19·50 | 28·49 | 45·77 | [5·23] | $H_2O$ 1·01 = 100 |
| 2*a*. | G. = 5·19 | ⅔ 20·15 | 41·04 | 34·76 | | |
| | | $CO_2$ | $(Ce,La,Di)_2O_3$ | (Ce,La,Di) | | |
| 2*b*[a]. | | 20·15 | 50·13 | 21·82 | [7·90] | = 100 |

[a] Calculated from 2*a*; joint atomic weight 140·2

**Pyr., etc.**—B.B. infusible. Slightly attacked by hydrochloric acid. Dissolves in strong sulphuric acid with effervescence ($CO_2$) and evolution of hydrofluoric acid.

**Obs.**—Found in small masses embedded between allanite crystals at the Bastnäs mine, Riddarhyttan, Sweden. Also as an alteration product of tysonite (p. 166) in the granite of the Pike's Peak region in Colorado. The basic fluocerine was from Finbo, Sweden.

Hamartite is from ἁμαρτειν, *to go astray*, but bastnäsite, from the locality, has the priority.

**Ref.**—[1] The hamartite of Nordenskiöld is described as occurring in hexagonal prisms (cf. also Dx., Min., **2**, 163, 1874), but it seems very probable that, like the mineral from Colorado, they are only pseudomorphs after an original fluoride like tysonite.

WEIBYEÏTE *W. C. Brögger*, Zs. Kr., **16**, 650, 1890. In minute pyramidal orthorhombic crystals with *p* (111), also subordinate *m* (110), a prism (10·9·0) or (540), and a dome (201) or (021). Angles $pp^{iv}$ = 95° 59′, $pp'''$ = 56° 44′ or near zircon. Optically biaxial, negative. Bx ⊥ 100 or 010. 2E = 110° approx. Colorless within but covered with a thin yellow ocher-like crust, and penetrated to some extent by the same substance.

Analysis, G. Forsberg:

| $CO_2$ | $Ce_2O_3$ | $La_2O_3,Di_2O_3$ | CaO | SrO | F | |
|---|---|---|---|---|---|---|
| 19·16 | 35·38 | 31·58[a] | 3·42 | 0·97 | 5·04 | X[b] 0·23 = 95·78 |

[a] $Di_2O_3$ = 9 p. c. approx.; at. weight = 139–140. [b] X = O in excess.

Deducting O (= F) 2·12 the sum is 93·66, leaving $H_2O$ (and loss) 6·34.

The mineral analyzed was mixed with the ocher-like substance mentioned, also with parisite or an allied mineral, and the interpretation of the analysis is otherwise doubtful, but a composition analogous to that of bastnäsite is suggested.

Found as a later formation on eudidymite, also with analcite and natrolite, on the island called Ovre-Arö, in the Langesundfiord, Norway. Named for the Norwegian mineralogist, P. C. Weibye.

---

## 5. Phosgenite Group. Chlorocarbonate. Tetragonal.

**286. PHOSGENITE.** Hornblei *Karst.*, Tab., 78, 1800. Salzsaures Bleierze *Klapr.*, Beitr., 3, 141, 1802. Corneous Lead *Jameson.* Bleihornerz, Chlorbleispath, *Germ.* Plomb carbonaté muriatifère, Plomb chloro-carbonaté, Plomb corné, *Fr.* Phosgen-spath *Breith.*, Char., 61, 1832. Kerasine *Beud.*, Tr., 2, 502, 1832. Phosgenit *Breith.*, Handb., 2, 183, 1841. Galenoceratite, Bleikerat, *Glocker*, Syn., 248, 1847. Cromfordite *Greg & Lettsom*, Min., 421, 1858.

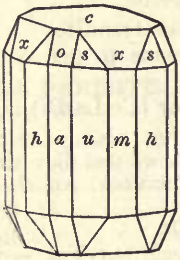
Tetragonal. Axis $\dot{c} = 1{\cdot}08758$; $001 \wedge 101 = 47° 24' 6''$ Koksharov[1].

| | | | | |
|---|---|---|---|---|
| **Forms**[2]: | *m* (110, *I*) | *h* (210, *i*-2) | *o* (201, 2-*i*) | *v* (311, 3-3)[3] |
| *c* (001, *O*) | *l* (310, *i*-3)[3] | *p* (203, ⅔-*i*)[3] | *x* (111, 1) | *s* (211, 2-2) |
| *a* (100, *i*-*i*) | | | | |

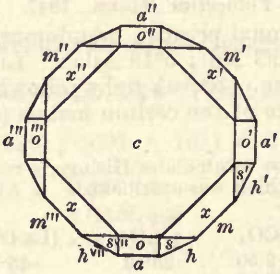
On pseudomorphs, also uncertain acute pyramids (f. 3), an octagonal prism[4], etc.

| | | | |
|---|---|---|---|
| *co* = 65° 19′ | *cs* = 67° 39′ | *xx′* = 72° 43′ | $ss^{vii}$ = 48° 52′ |
| *cx* = 56° 58′ | *oo′* = 79° 57′ | *ss′* = 34° 1′ | *xs* = 19° 27′ |

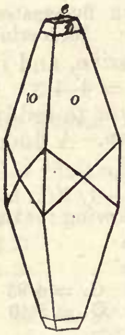
1.



2.



3.



Figs. 1, 2, Monte Poni, Kk. 3, Silesia (pseudomorph), Kr. v. Nidda[4].

Crystals prismatic; sometimes tabular ∥ *c*.

Cleavage: *m*, *a* distinct; also *c*. Rather sectile. H. = 2·75–3. G. = 6·0–6·09, Lovisato; 6·305 Rg. Luster adamantine. Color white, gray, and yellow. Streak white. Transparent to translucent. Optically +. Indices: $\omega = 2{\cdot}114$, $\epsilon = 2{\cdot}140$ orange rays, Sella (Dx.).

**Comp.**—Chlorocarbonate of lead, $(PbCl)_2CO_3$ or $PbCO_3.PbCl_2$ = Carbon dioxide 8·1, chlorine 13·0, lead oxide 81·9 = 103; or Lead carbonate 49·0, lead chloride 51·0 = 100.

Analyses, see 5th Ed., p. 703.

**Pyr., etc.**—B.B. melts readily to a yellow globule, which on cooling becomes white and crystalline. On charcoal in R.F. gives metallic lead, with a white coating of lead chloride. With a salt of phosphorus bead previously saturated with copper oxide gives the chlorine reaction. Dissolves with effervescence in dilute nitric acid.

**Obs.**—At Cromford near Matlock in Derbyshire, in crystals sometimes 2 or 3 inches long; very rare in Cornwall; in minute crystals at a lead mine near Elgin in Scotland; in large crystals at Gibbas, Monte Poni and Montevecchio in Sardinia; near Bobrek in Upper Silesia.

A recent formation at Bourbonne-les-Bains; also at Laurion, Greece, where it is the result of the action of the sea-water upon ancient lead slags, in the cavities of which it occurs with laurionite (wh. see, p. 171).

**Alt.**—Occurs at the Elisabeth zinc mine, Upper Silesia, altered to lead carbonate, the crystals are acute tetragonal pyramids (f. 3), sometimes with a zirconoid or an octagonal prism; they are embedded in clay. Cf. thinolite, p. 271.

**Artif.**—Cf. Friedel & Sarasin, Bull. Soc. Min., **4**, 175, 1881.

**Ref.**—[1] Mte. Poni, Min. Russl., **8**, 118, 1881; cf. Hansel, Zs. Kr., **2**, 291, 1878. [2] Cf. Mlr. Min., 622, 1852. [3] Rath, Laurium, Ber. nied. Ges., 102, 1887. [4] Krug v. Nidda, Zs. G. Ges., **2**, 126, 1850.

**287. TESCHEMACHERITE.** Bicarbonate of Ammonia *E. F. Teschemacher*, Phil. Mag., **28**, 548, 1846. Teschemacherite *Dana*, Min., 705, 1868.

Orthorhombic. In crystals with prismatic cleavages at 68°. H. = 1·5. G. = 1·45. Yellowish to white.

**Comp.**—Acid ammonium carbonate, $HNH_4CO_3$ or $(NH_4)_2CO_3.H_2CO_3$ = Carbon dioxide 55·7, ammonia 32·9, water 11·4 = 100.

Analysis.—Phipson, J. Ch. Soc., **16**, 74, 1863.

| | $CO_2$ | $(NH_4)_2O$ | $H_2O$ | CaO | |
|---|---|---|---|---|---|
| Chincha Islands | 51·53 | 29·76 | 11·00 | 6·02 | $P_2O_5$ 0·60, MgO, $SO_3$, Cl *tr.*, alk. and uric [acid 1·09 = 100 |

The material analyzed by Phipson was white, compact, crystalline, and fragile, and had a strong odor of ammonia, from which he infers the presence either of free ammonia or of sesquicarbonate.

**Pyr., etc.**—In the closed tube for the most part volatilized, giving the odor of ammonia, a white sublimate of ammonium carbonate, while an abundance of water condenses on the tube. Soluble in water, and heated with a fixed alkali gives a strong odor of ammonia. Effervesces with acids. Reacts alkaline to test paper.

**Obs.**—From guano deposits on the coast of Africa and Patagonia, and the Chincha Islands. Forms a bed several inches thick in the lowest parts of the guano deposits of Patagonia, as announced by Teschemacher; similarly at the Chincha Islands, according to Phipson.

On the form, etc., of the artificial ammonium carbonate, see Rose, Pogg., **46**, 400, 1839; also Rg., Kr. Ch., **1**, 545, 1881.

KALICINE *Pisani*, C. R., **60**, 918, 1865. Potassium bicarbonate. Announced as found under a dead tree at Chypis in Valais, as a result of recent decomposition. Pisani obtained for its composition: $CO_2$ 42·20, $K_2O$ 42·60, $H_2O$ 7·76, $CaCO_3$ 2·50, $MgCO_3$ 1·34, sand, etc. 3·60 = 100.

Twins: tw. pl. *a* very common; often as penetration-twins. Crystals, usually slender, acicular prisms, grouped in tufts and rosettes. Form seldom distinct; faces uneven; *a, m, b* vertically striated; *v, α, β* striated ‖ edge *v*/*α*. Commonly massive or incrusting, with surface tuberose, botryoidal, or stalactitic, and structure divergent; often delicately compact fibrous, and banded in color; frequently granular or earthy.

Cleavage: *c* perfect; *b* less so. Fracture subconchoidal, uneven. Brittle. H. = 3·5–4. G. = 3·9–4·03. Luster of crystals adamantine, inclining to vitreous; of fibrous varieties more or less silky; often dull and earthy. Color bright green. Streak paler green. Translucent to subtranslucent to opaque.

Optically —. Ax. pl. ‖ *b*. $\text{Bx}_\text{a} \wedge \acute{c} = 23° \ 29'$ red, 23° 31′ yellow. Dispersion $\rho < v$ in the air, $\rho > v$ within, rather large; inclined feeble. Axial angles, Dx.:

$$2\text{E}_\text{r} = 89° \, 14', 2\text{E}_\text{y} = 89° \, 18'; \ \beta_\text{r} = 1{\cdot}87, \ \beta_\text{y} = 1{\cdot}88 \ \therefore \ 2\text{V}_\text{r} = 44° \, 7', 2\text{V}_\text{y} = 43° \, 54'$$

**Comp.** = Basic cupric carbonate, $CuCO_3.Cu(OH)_2$ or $2CuO.CO_2.H_2O$ = Carbon dioxide 19·9, cupric oxide 71·9, water 8·2 = 100.

**Pyr., etc.**—In the closed tube blackens and yields water. B.B. fuses at 2, coloring the flame emerald-green; on charcoal is reduced to metallic copper; with the fluxes reacts like cuprite, p. 206. Soluble in acids with effervescence.

**Obs.**—Common with other ores of copper and as a product of their alteration; thus as a pseudomorph after cuprite and azurite. Occurs abundantly in the Ural; at Chessy in France; massive at Schwatz in Tyrol; in Cornwall and in Cumberland, England; Sandlodge copper mine, Shetland, Scotland; Limerick, Waterford, and elsewhere, Ireland; at Saalfeld; Rheinbreitbach; Dillenburg, Nassau; Betzdorf near Siegen. At the copper mines of Nizhni Tagilsk a bed of malachite was opened which yielded many tons of malachite; one mass measured at top 9 by 18 ft.; and the portion uncovered contained at least half a million pounds of pure malachite. Also in handsome masses at Bembe, on the west coast of Africa; with the copper ores of Cuba; Chili; at the Cobar mines and elsewhere in New South Wales; South Australia.

Occurs in *Conn.*, sparingly at Cheshire. In *N. Jersey*, at Schuyler's mines, and still better at New Brunswick. In *Pennsylvania*, in the Blue Ridge, near Nicholson's Gap; near Morgantown, Berks County; at Cornwall, Lebanon Co., in good specimens; at the Perkiomen and Phenixville lead-mines. In *Maryland*, between Taneytown and Newmarket, E. of the Monocacy; in the Catoctin Mts. In *Wisconsin*, at the copper mines of Mineral Point, and elsewhere. In *California*, at Hughes's mine, in Calaveras Co. Abundantly in fine masses and acicular crystals, with calcite at the Copper Queen mine, Bisbee, Cochise Co., *Arizona*; also in Graham Co., especially at the Humming Bird mine, Morenci (6 m. from Clifton), where beautiful stalactitic forms of malachite and azurite in concentric bands are obtained. At the Santa Rita mines, Grant Co., and elsewhere in *New Mexico*. Tintic district, *Utah*.

Named from *μαλαχή*, *mallows*, in allusion to the green color.

**Artif.**—Obtained by de Schulten in acicular crystals, C. R., **110**, 202, 1890.

**Ref.**—[1] The fundamental angles taken by Dx. (Min., **2**, p. 185) are accepted here, viz.: *ac*, *mm‴* Hbg., Rheinbreitbach (Min. Not., **6**, 9, **7**, 32), *a′w* Lang, Nizhni Tagilsk; with Lang *x* = 001, Phil. Mag., **25**, 432, 1863, **28**, 502, 1864. See also Zeph., Ber. Ak. Wien, **51** (1), 112, 1865.

LIME-MALACHITE. Kalk-malachit *Zincken*, B. H. Ztg., **1**, 1842. Calco-malachite. Massive, reniform, botryoidal; structure fibrous and foliated. H. 2·5. Luster silky. Color verdigris-green. From Zincken's trials it is a hydrous carbonate of copper, with some carbonate and sulphate of calcium and iron. The original from Lauterberg in the Harz; a similar substance elsewhere, as in Arizona. Probably simply malachite impure with gypsum or calcite, or in some cases both.

MYSORIN *Thomson*, Min., **1**, 601, 1836. An impure malachite according to F. R. Mallet, Rec. Geol. Survey India, **12**, 166, 1879, and Min. India, 156, 1887. From Mysore, India.

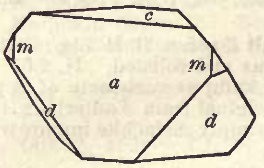
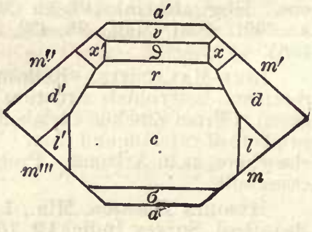
5.



6.



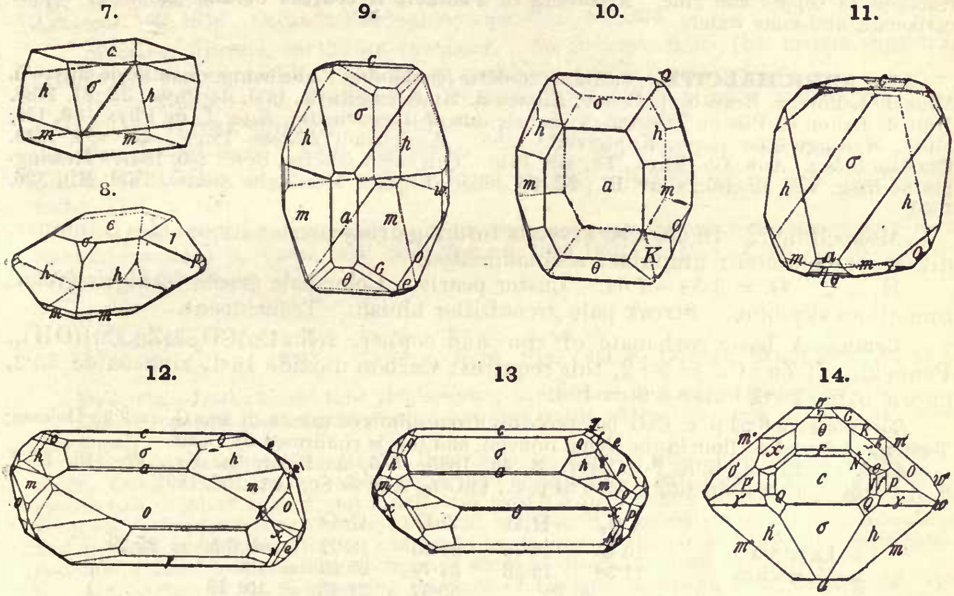
Figs. 1, 2, Chessy. 3, Nizhni Tagilsk. 4, Chessy. 5, Banat. 1–6, after Schrauf (Rose, Zippe).

Twins: tw. pl. (1) $v\ (\bar{2}01)$ Dx.; 2, $\theta\ (\bar{1}01)$ Groth[5]; not common. Crystals varied in habit and highly modified; often tabular ∥ *c*, or $\sigma$ (101) or $\theta$ (101), also prismatic ∥ $\grave{c}$, *m* prominent, and again elongated ∥ axis $\bar{b}$; sometimes rhombohedral in aspect. Faces usually slightly undulating; *c* striated ∥ edge *p*/*f*, and *a* ∥ edge *a*/*c*. Also massive, and presenting imitative shapes, having a columnar composition; also dull and earthy.

Cleavage: $p$ (021) perfect but interrupted; $a$ less perfect; $m$ in traces. Fracture conchoidal. Brittle. H. = 3·5–4. G. = 3·77–3·83. Luster vitreous, almost adamantine. Color various shades of azure-blue, passing into berlin-blue. Streak blue, lighter than the color. Transparent to subtranslucent.

Optically +. Ax. pl. $\perp b$. $Bx_a \wedge \dot{c} = -12° 36'$. Dispersion $\rho > v$ considerable; horizontal distinct. Axial angles for rays between green and blue:

$$2H = 82° 5' \text{ and } 2E = 151°, \text{Dx.}$$



7–14, Arizona, Farrington.

**Comp.**—Basic cupric carbonate, $2CuCO_3.Cu(OH)_2$ or $3CuO.2CO_2H_2O$ = Carbon dioxide 25·6, cupric oxide 69·2, water 5·2 = 100.

For analyses, see 5th Ed., p. 716; they agree closely with the requirements of the formula.

**Pyr., etc.**—Same as in malachite.

**Obs.**—Occurs in splendid crystallizations at Chessy, near Lyons, whence it derived the name *Chessy Copper* or *chessylite*. Also in fine crystals in Siberia; at Moldawa in the Banat; at Wheal Buller, near Redruth in Cornwall; also in Devonshire and Derbyshire, England; in small quantities at Alston-Moor and Wanlockhead, etc.; at Puerto Cabello, S. A.; Cobar mines and elsewhere in New South Wales; South Australia.

Occurs in *Penn.*, at the Perkiomen lead mine, in indifferent specimens, associated with galena, sphalerite, and cerussite; at Phenixville, in crystals; at Cornwall, in crystals on red shale; near Nicholson's Gap, in the Blue Ridge. In *N. York*, near Sing Sing. In *N. Jersey*, near New Brunswick. In *Wisconsin*, at the old copper diggings near Mineral Point, in good crystals; also at the Bracken mine, in small but fine crystals. In *Arizona*, at the Longfellow mine, also other mines in Graham Co.; also with malachite in beautiful crystals at the Copper Queen mine, Bisbee; at the Clifton mines, Graham Co. In Grant Co., *New Mexico*. At the Mammoth mine in the Tintic district, *Utah*, with various copper arsenates. In *California*, Calaveras Co., at Hughes's mine, in crystals.

**Alt.**—Azurite is often altered to malachite through the loss of carbon dioxide and addition of water; also to native copper, as at Grant Co., New Mexico, Yeates, Am. J. Sc., **38**, 405, 1889.

**Artif.**—Formed artificially by Debray, Becquerel, Michel; cf. Bull. Soc. Min., **13**, 139, 1890.

**Ref.**—[1] Ber. Ak. Wien, **64** (1), 123, 1871 and Atlas, XXVI–XXIX, 1872. This is the position of Haidinger (Min. Mohs, **2**, 167, 1825); Zippe, Pogg., **22**, 393, 1831; Miller (Min., p. 594, 1852); with Rose (Reis. Ural, **1**, 315, 541, 1837), Lévy (Heuland, **3**, 64, 1837). With Schrauf (l. c.) the vertical axis has double the length, i.e. $h = 111$, etc. Schrauf points to a similarity of form between azurite and epidote.

[2] See Schrauf for review and correction of earlier authorities, also Dx., Min., **2**, 190, 1874. A note in Zs. Kr., 8, 532, credits Krenner and Franzenau with having observed on crystals from Utah also (507), and (223), no angles given. Cf. also Gdt., Index, **2**, 269, 1888, who gives some planes not included here. [3] H. S. Washington, Arizona, priv. contr. [4] Farrington, Arizona, Am. J. Sc., **41**, 300, 1891. [5] Min.-Samml., Strassb., 139, 1878.

ATLASITE *Breith.*, B. H. Ztg., **24**, 310, 1865. A carbonate of copper containing chlorine from Chañarcillo, Chili. It resembles atacamite, and may be a mixture of this species and azurite. See further 5th Ed., p. 716.

ZINKAZURITE *Breith.*, B. H. Ztg., **11**, 101, 1852. A blue mineral in small crystals, having G. = 3·49, from the Sierra Almagrera in Spain. Heated, it affords a little water, with the reactions of copper and zinc. According to Plattner, it consists of zinc sulphate, copper carbonate, and some water.

**290. AURICHALCITE.** Calamine verdâtre (containing "une bonne quantité de cuivre"), Mine de Laiton [= Brass-ore], *Patrin*, Aperçu d. Mines en Sibèrie, in J. de Phys., **33**, 81, 1788. Mine de Laiton de Pise en Toscane, Aurichalchum of the ancients?, *Sage*, J. de Phys., **38**, 155, 1791. Messingblüthe *Germ.* Kupferzinkblüthe. Aurichalcit *Böttger*, Pogg, **48**, 495, 1839. Buratite *Delesse*, Ann. Ch. Phys., **18**, 478, 1846. Orichalcit *Glocker*, Syn., 230, 1847. Messingblüthe *Risse*, Ver. Rheinl., Corr.-Bl., **22**, 95, 1865. Risséite, Messingite *Adam.*, Tabl. Min., 26, 1869.

Monoclinic[1]?. In acicular crystals forming drusy incrustations; also columnar, divergent; plumose; granular; also laminated.

H. = 2. G. = 3·54–3·64. Luster pearly. Color pale green, verdigris-green; sometimes sky-blue. Streak pale greenish or bluish. Translucent.

**Comp.**—A basic carbonate of zinc and copper, $2(Zn,Cu)CO_3.3(Zn,Cu)(OH)_2$, Penfield. If Zn : Cu = 5 : 2, this requires: Carbon dioxide 16·1, zinc oxide 53·2, cupric oxide 20·8, water 9·9 = 100.

*Buratite* gave 8·62 p. c. CaO but probably from admixed calcite, it has G. = 3·32 Delesse; Tschermak found no lime in the Banat mineral, and this is confirmed by Belar.

**Anal.**—1, Pisani, Bull. Soc. Min., 8, 43, 1885. 2–5, A. Belar, Zs. Kr., **17**, 113, 1889. 6, 7, Penfield, after deducting 1·53, 0·64 p. c., $CaCO_3$, Am. J. Sc., **41**, 106, 1891.

| | | $CO_2$ | $H_2O$ | ZnO | CuO | |
|---|---|---|---|---|---|---|
| 1. Laurium | | 15·45 | 14·75 | 50·45 | 18·07 | insol. 0·50 = 99·22 |

| 7. " | G. = 3·64 | 16·04 | 9·99 | 54·36 | 20·00 | = 100·39 |

**Pyr., etc.**—In the closed tube blackens, and yields water. B.B. infusible; colors the flame deep green. With soda on charcoal gives a coating of zinc oxide; the fused mass removed from the coal and triturated in a mortar affords minute globules of copper. With the fluxes reacts for copper. Soluble in acids with effervescence.

**Obs.**—Aurichalcite occurs at Loktevski, at a copper mine in the Altai, where it is associated with calcite and limonite, sometimes forming a drusy covering upon these minerals; at Morawitza in the Banat; Chessy, near Lyons; Rezbanya, in Hungary; Campiglia in Tuscany; at Matlock in Derbyshire, of a pale green color, laminated structure, and pearly luster; at Roughten-Gill, in Cumberland; Leadhills, Scotland; zinc mines of the province of Santander, Spain; at the zinc mines of Laurium, Greece.

In the U. S., at Lancaster, Pa.; from the Santa Caterina Mts., Arizona, in fine specimens, reported also from the Copper Queen mine, Bisbee. At the Kesler mine, Big Cottonwood, and the Cave mine in Beaver Co., Utah.

The mineral aurichalcite was first described as a greenish variety of calamine by Patrin, in 1788 (l. c.), and called *Brass ore* (Mine de Laiton), "because," as he says, "the compound of copper and zinc is here made by nature." Among the brass or copper ores of the ancients, *aurichalcum* was reputed the best (Pliny, 33, 2); and Sage was thence led to suggest (l. c., 1791) that the *cupriferous calamine* (which afforded, as he showed by experiment, the best of brass, without the addition of either copper or zinc) might be the ancient *aurichalcum*. As the ore is a scarce one, this is not at all probable. But the idea explains the use of the word for the species. In addition, it is to be said that brass (or an alloy related to it) was called *aurichalcum* by Virgil and Horace, and also in the middle ages.

The Latin word *aurichalcum* is regarded by some good authorities as derived from ʼορείχαλκος (= *mountain brass*); and, in fact, the Latin poets just mentioned wrote it *orichalcum*. But others regard it as a hybrid word (from the Latin *aurum*, *gold*, and χαλκὸς, *brass* or *bronze*), and the *o* of the poets as an example of the admissible change in

Latin of *au* to *o*. Glocker, in view of the first of these derivations, changes aurichalcite to *orichalcite;* but, whatever the derivation, as the use of *aurichalcum* dates from before Pliny's time, we moderns may as well let it stand without correction.

*Buratite* is named from M. Burat, who is stated to have discovered the mineral in Italy.

**Artif.**—Cf. Delesse, l. c.; also Belar, who throws doubt upon the observations of Delesse.

**Ref.**—[1] For observations on the form see Belar, l. c.

**291. HYDROZINCITE.** Calamine *Smithson*, Phil. Trans , 12, 1803. Zinkblüthe *Karst.*, Tabell., 70, 99, 1808. Hydro-carbonate of Zinc. Earthy calamine. Zinconise *Beud.*, Tr., 2, 357, 1832. Zinc Bloom. Hydrozinkit *Kenng.*, Min., 1853. Marionite *Elderhorst*, G. Rep. Arkansas, 153, 1858. Cegamit *Weisbach*, Synops. Min., 36, 1875.

Massive, fibrous, earthy or compact. As incrustations, the crusts sometimes concentric and agate-like. At times reniform, pisolitic, stalactitic.

H. = 2–2·5. G. = 3·58–3·8. Luster dull. Color pure white, grayish or yellowish. Streak shining. Usually earthy or chalk-like.

**Comp.**—A basic zinc carbonate, exact composition uncertain, perhaps $ZnCO_3.2Zn(OH)_2$ or $3ZnO.CO_2.2H_2O$ = Carbon dioxide 13·6, zinc oxide 75·3, water 11·1 = 100.

Analyses vary somewhat widely probably, in consequence of want of homogeneity in the material examined: 1, Cossa, Att. Soc. Tor., 6, 189, 1870. 2, V. v. Zotta, Zs. Kr., 13, 143, 1887. Also 5th Ed., p. 711.

| | $CO_2$ | ZnO | $H_2O$ | |
|---|---|---|---|---|
| 1. Auronzo | 14·55 | 73·21 | 11·83 | = 99·59 |
| 2. Bleiberg | 17·05 | 70·76 | 10·30 | PbO 1·26, $Fe_2O_3$ 0·42, $SiO_2$ 0·36 = 100·15 |

**Pyr., etc.**—In the closed tube yields water; in other respects resembles smithsonite.

**Obs.**—Occurs at most mines of zinc, and is a result of the alteration of the other ores of this metal.

Found in great quantities at the Dolores mine, Udias valley, province of Santander, in Spain, along with calamine, smithsonite, and sphalerite, covering the floor of an extensive cavern to a depth of a yard and a half, and hanging in dazzling white branching stalactites from the roof; part is concretionary, pisolitic, nodular; it is intimately mixed with zinc silicate, and is pseudomorphous after it; and opal-like masses of silicate and hydrous carbonate are common, formed by the falling of drops of water holding the silicate in solution.

Also occurs in the neighboring province of Guipuzcoa, Spain, near La Nestosa, at the mines of Las Nieves and La Augustina; at Bleiberg and Raibel in Carinthia; near Reimsbeck, in Westphalia; in Höllenthal, on the Zugspitze in Bavaria; at Taft in the province of Jesd in Persia.

In the U. S., at Friedensville, Pa.; at Linden, in Wisconsin, as a concretionary fibrous white crust on smithsonite; in Marion Co., Arkansas (*marionite*), in concentric and contorted laminæ and botryoidal crusts; with sphalerite, etc., at Joplin, Mo.

Beudant's name *zinconise*, from zinc and κόνις, powder, has priority, but is too badly formed to be retained.

**Artif.**—Deposited when hot solutions of zinc salts in water are decomposed by carbonates of the alkalies. The white substance formed on zinc, when moistened and exposed to the air, is a related compound. Belar (Zs. Kr., 17, 123, 1889) describes an artificial hydrous zinc carbonate, $ZnCO_3 + H_2O$, in crystals resembling hydromagnesite in habit.

**292. HYDROCERUSSITE.** *A. E. Nordenskiöld*, G. För. Förh., 3, 381, 1877. Hydrocerusite. Plumbonacrite *Heddle*, Min. Mag., 8, 201, 1889.

In thin hexagonal planes, optically uniaxial, negative Lcx.[1]

Soft. G. = 6·14, artif. cryst. Colorless. Luster pearly.

**Comp.**—A basic lead carbonate, probably $2PbCO_3.Pb(OH)_2$ or $3PbO.2CO_2.H_2O$ = Carbon dioxide 11·4, lead oxide 86·3. water 2·3 = 100.

**Pyr., etc.**—Yields lead on charcoal. Soluble in acid with evolution of carbon dioxide.

**Obs.**—Occurs sparingly as a coating on native lead, at Långban, Wermland, Sweden. Also in cavities in galena at Wanlockhead, Scotland.

**Artif.**—An artificial basic lead carbonate with the above composition is described by Bourgeois, Bull. Soc. Min., 11, 221, 1888.

**Ref.**—[1] Bull. Soc. Min., 8, 35, 1885.

**293. DAWSONITE.** *B. J. Harrington*, Can. Nat., 7, 305, 1874.

Monoclinic ?. In thin incrustations of radiating bladed crystals.

Cleavage: longitudinal easy. H. = 3. G. = 2·40. Luster vitreous. Color white. Transparent to translucent. Double refraction strong. Ax. pl. transverse to needles and nearly ⊥ to the cleavage; axial angle large, Dx.[1]

**Comp.**—A basic carbonate of aluminium and sodium, $Na_3Al(CO_3)_3.2Al(OH)_3$ or $Na_2O.Al_2O_3.2CO_2.2H_2O$ = Carbon dioxide 30·6, alumina 35·4, soda 21·5, water 12·5 = 100.

**Anal.**—1, 2, Harrington, l. c. 3, *Id.*, ibid., **10**, 84, 1881 after deducting calcite. 4, Friedel, Bull. Soc. Min., **4**, 28, 1881.

| | $CO_2$ | $Al_2O_3$ | $Na_2O$ | $H_2O$ | |
|---|---|---|---|---|---|
| 1. Montreal | 29·88 | 32·84 | 20·58[a] | 11·91 | MgO *tr.*, CaO 5·95 = 101·16 |
| 2. " | 30·72 | 32·68 | 20·17 | [10·33] | MgO 0·45, CaO 5·65 = 100 |

| 4. Tuscany | 29·09 | 35·89 | 19·13 | 12·00 | MgO 1·39, CaO 0·42 = 97·92 |

[a] Incl. $K_2O$ 0·38.

**Pyr.**—B.B. swells up, colors the flame deep yellow, and after ignition yields an alkaline reaction; gives a fine blue with cobalt nitrate; in the closed tube yields water and carbon dioxide. Soluble in acids with effervescence.

**Obs.**—Found as a crystalline coating, resembling tremolite, on the jointed surfaces of a feldspathic dike cutting the Trenton limestone near McGill College, Montreal; it is associated with calcite, dolomite, pyrite, etc. Also from the province of Siena, Piau Castagnaio, Tuscany, in a quartzose rock, impregnated with dolomite, in part argillaceous; associated with calcite, dolomite, pyrite, fluorite, and cinnabar.

**Ref.**—[1] Bull. Soc. Min., **1**, 8, 1878.

HOVITE. Native Carbonate of Alumina and Lime, *J. H. & G. Gladstone*, Phil. Mag., **23**, 461, 1862.

A soft white earthy substance from fissures in flint at an old quarry in the Upper Chalk, at Hove near Brighton. Analyses show silica, carbon dioxide, alumina, lime and water; it may be a carbonate of alumina and lime, but very impure and of doubtful nature. See 5th Ed., p. 709.

---

**294. THERMONATRITE.** *Νιτρον* and Nitrum pt. *Vet.* Natron, Alkali orientale impurum terrestre, Jordblandadt Alkaliskt-salt, *Wall.*, Min., 174, 1747. Natürliches mineralisches Alkali *Wern.* Prismatisches Natronsalz *Mohs.* Thermonatrit *Haid.*, Handb. 487, 1845. Thermonitrit *Hausm.*, Handb., 1411, 1847. Soude carbonatée prismatique *Dufr.*

Orthorhombic. Axes $\breve{a} : \bar{b} : \acute{c}$ = 0·8268 : 1 : 0·8089 Marignac[1].
100 ∧ 110 = 39° 35′, 001 ∧ 101 = 44° 22½′, 001 ∧ 011 = 38° 58⅙′.

**Forms** (artif. cryst.): *b* (010, *i*-ĭ) *m* (110, *I*) *u* (101, 1-ī) *p* (122, 1-2̆)
*a* (100, *i*-ī) *c* (001, *O*) *g* (102, ½-ī) *e* (021, 2-ĭ)

*mm‴* = *79° 10′ *gg′* = 52° 8′ *ee′* = 116° 33½′ *pp″* = 86° 47′
*ag* = *63° 56′ *uu′* = 88° 45′ *pp′* = 41° 39′ *pp‴* = 72° 0½′

Often in flattened crystals ∥ *c* or *a*, also prismatic *c*. Usually as an efflorescence.

Cleavage: *b* difficult. Somewhat sectile. H. = 1–1·5. G. = 1·5–1·6. Luster vitreous. White, grayish, yellowish. Taste alkaline.

**Comp.**—Hydrous sodium carbonate, $Na_2CO_3 + H_2O$ = Carbon dioxide 35·5, soda 50·0, water 14·5 = 100.

**Obs.**—Occurs in various lakes, and as an efflorescence over the soil in many dry regions of the globe; also about some mines and volcanoes. It results from the efflorescence of natron.

**Ref.**—[1] Ann. Mines, **12**, 55, 1857; cf. the somewhat different results of Haid., Ed. J. Sc., **2**, 327, 1825 or Pogg., **5**, 369, 1825.

**295. NESQUEHONITE.** *F. A. Genth* and *S. L. Penfield*, Am. J. Sc., **39**, 121, 1890.

Orthorhombic. Axes $\breve{a} : \bar{b} : \acute{c}$ = 0·64446 : 1 : 0·45678 Penfield.
100 ∧ 110 = 32° 48′, 001 ∧ 101 = 35° 19⅔′, 001 ∧ 011 = 24° 33′.

**Forms**: *b* (010 *i*-ĭ), *c* (001, *O*), *m* (110, *I*), *d* (011, 1-ĭ). Angles (approx.): *mm‴* = *65° 36′, *dd′* = *49° 6′.

In prismatic crystals, usually united in radiating groups; prismatic faces deeply striated vertically.

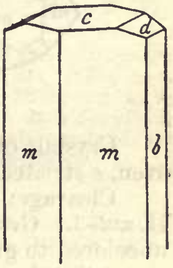
Cleavage: *m* perfect; *c* less so. Fracture splintery ‖ *m*. H.=2·5. G.=1·83–1·85. Luster vitreous or slightly greasy. Colorless to white. Transparent to translucent. Optically —. Ax. pl. ‖ *c*. Bx ⊥ 100. Dispersion small, $\rho < v$. Axial angles, Pfd.:

$2E_r = 83° 55'$ Li  $2E_y = 84° 15'$ Na  $2E_{gr} = 84° 22'$ Tl

Also (artif. cryst.) $\beta_y = 1·501$  $\gamma_y = 1·526$ ∴ $2V_y = 53° 5'$ and $\alpha = 1·495$.

**Comp.**—Hydrous magnesium carbonate, $MgCO_3 + 3H_2O$ = Carbon dioxide 31·4, magnesia 29·0, water 39·1 = 100.

**Anal.**—1, 2, Genth, l.c.: 1, original crystals; 2, material pseudomorphous after lansfordite.



| | $CO_2$ | MgO | $H_2O$ | | |
|---|---|---|---|---|---|
| 1. | 30·22 | 29·22 | 40·32 | = | 99·76 |
| 2. | 28·85 | 28·23 | 42·92 | = | 100 |

**Obs.**—From an anthracite coal mine at Nesquehoning, 4 miles from Lansford, Schuylkill Co., Penn.; when found it formed the base of stalactites and incrustations, the remainder of which consisted of lansfordite, out of which it had been formed; later the entire stalactites became altered into a white chalky substance with fibrous structure which was also nesquehonite (cf. lansfordite, p. 305).

**Artif.**—Deposited in crystals from a solution of $MgCO_3$ in water containing carbon dioxide; they are identical with the natural crystals. Cf. Pfd., l. c., also Mitsch., Mem. Soc. Genève, **14**, 252, 1855.

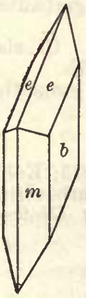
**296. NATRON.** *Νιτρον*, Nitrum, *of the Ancients.* Hemiprismatisches Natronsalz *Mohs.* Natrit *Weisbach,* Synops. Min., p. 7, 1875. Soda. Carbonate of Soda. Sodium Carbonate. Soude carbonatée.

Monoclinic. Axes: $\grave{a} : \bar{b} : \dot{c} = 1·4828 : 1 : 1·4001$; $\beta = *58° 52' = 001 \wedge 100$ Haidinger[1].

$100 \wedge 110 = 51° 46'$, $001 \wedge \bar{1}01 = 57° 39\frac{1}{3}'$, $001 \wedge 011 = 50° 9\frac{1}{2}'$

**Forms** (artif. cryst.)[1]: *a* (100, *i-ī*), *b* (010, *i-ì*), *c* (001, *O*); *m* (110, *I*); *s* ($\bar{1}$01, 1-*ī*); *e* (011, 1-*ì*), *p* ($\bar{1}$12, ½).

Angles: $mm''' = *103° 32'$, $a's = 63° 29'$, $ee' = *100° 19'$, $cm = 71° 20'$, $cp = 43° 43'$, $pp' = 69° 55'$.



Twins: tw. pl. *c*. Crystals tabular ‖ *b*.

Cleavage: *c* distinct; *b* imperfect; *m* in traces. Fracture conchoidal. Brittle. H. = 1–1·5. G. = 1·42–1·46. Vitreous to earthy. White, sometimes gray or yellow, owing to impurities. Taste alkaline. Optically—. Ax. pl. and $Bx_a$ ⊥ *b*. $Bx_o \wedge \dot{c} = +41° 8'$. Dispersion $\rho > v$ small. Axial angles:

$2E_r = 112° 48'$  $2E_y = 112° 42'$ Dx.

**Comp.**—Hydrous sodium carbonate, $Na_2CO_3 + 10H_2O$ = Carbon dioxide = 15·4, soda 21·7, water 62·9 = 100.

**Obs.**—Occurs in nature only in solution, as in the soda lakes of Egypt and elsewhere, or mixed with the other sodium carbonates. See *Trona* and *Thermonatrite.*

**Ref.**—[1] Ed. J. Sc., **2**, 326, 1825, or Pogg., **5**, 369, 1825. Cf. also Dx., Min., **2**, 168, 1874; Rg., Kr. Ch., 549, 1881.

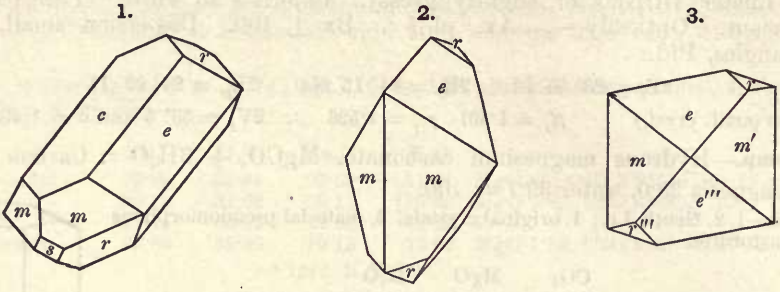
**297. GAY-LUSSITE** *Boussingault,* Ann. Ch. Phys., **31**, 270, 1826. Gaylussite.

Monoclinic. Axes $\grave{a} : \bar{b} : \dot{c} = 1·4897 : 1 : 1·4442$; $\beta = 78° 26\frac{3}{4}' = 001 \wedge 100$ Phillips[1].

$100 \wedge 110 = 55° 35'$, $001 \wedge \bar{1}01 = 49° 41\frac{1}{3}'$, $001 \wedge 011 = 54° 45'$.

**Forms**[1]: *a* (100, *i-ī*), *b* (010, *i-ì*), *c* (001, *O*); *m* (110, *I*); *s* ($\bar{1}01$, 1-*ī*); *e* (011. 1-*ì*); *r* ($\bar{1}12$, ½).

*mm'''* = *111° 10' *ee'* = *109° 30' *cm* = *83° 30' *me* = 42° 21
*a's* = 51° 52' *cr* = 43° 20' *rr'* = 69° 29' *er* = 27° 44'



1, South America. 2, 3, Ragtown, Nevada.

Crystals often elongated ∥ $\breve{a}$; also flattened wedge-shaped: surfaces usually uneven, *e* striated ∥ edge *e/r*.

Cleavage: *m* perfect; *c* rather difficult. Fracture conchoidal. Very brittle. H. = 2–3. G. = 1·93–1·95. Luster vitreous. Color white, yellowish white. Streak uncolored to grayish. Translucent. Optically —. Ax. pl. and $Bx_a \perp b$. $Bx_o \wedge \dot{c}$ = −14° 48′ red, −13° 8′ blue. Dispersion $\rho < v$, and crossed large. Axial angles:

At 17° C. $2E_r$ = 51° 38′ $2E_{bl}$ = 52° 53′ At 71·5° $2E_r$ = 53° 32′ Dx.

**Comp.**—Hydrous carbonate of calcium and sodium, $CaCO_3.Na_2CO_3 + 5H_2O$ = Calcium carbonate 33·8, sodium carbonate 35·8, water 30·4 = 100.

**Pyr., etc.**—Heated in a closed tube decrepitates and becomes opaque. B.B. fuses easily to a white enamel, and colors the flame intensely yellow. Dissolves in acids with a brisk effervescence; partly soluble in water, and reddens turmeric paper.

**Obs.**—Abundant at Lagunilla, near Merida, in Venezuela, where its crystals are disseminated at the bottom of a small lake, in a bed of clay, covering *urao;* the natives call them *clavos* or *nails*, in allusion to their crystalline form.

Also abundant in Little Salt Lake, or Soda Lake, in the Carson desert near Ragtown, Nevada. The lake is in a crater-shaped basin, and its waters are dense and strongly saline; the gay-lussite is deposited upon the evaporation of the water; it also occurs in another smaller Soda lake in the same neighborhood.

Named after Gay Lussac, the French chemist (1778–1850).

**Artif.**—Obtained by various methods, also in connection with soda manufacture. Cf. Arzruni, l. c., and authors quoted by him; also Rg., J. pr. Ch., **35**, 106, 1887.

**Alt.**—On the supposed pseudomorphs (*natrocalcite*) after gay-lussite from Sangerhausen ("Gerstenkörner") and elsewhere, see p. 907 and p. 271.

**Ref.**—[1] Accepted by Dx., Min., **2**, 171, 1874; earlier, Ann. Ch. Phys., **7**, 489, 1843. Cf. also Cordier, Ann. Ch. Phys., **31**, 276, 1826; Ph., Phil. Mag., **1**, 263, 1827; Mlr., 597, 1852.

On Nevada crystals, Blake, Am. J. Sc., **42**, 221, 1866. On the form and optical properties of artificial crystals, cf. Arzruni, Zs. Kr., **6**, 24, 1882, who gives general literature.

**298. LANTHANITE.** Kohlensaures Cereroxydul *Berz.*, Zs. f. Min., **2**, 209, 1825; Kohl. Ceroxydul *Hisinger*, Afh. Min. Geog. Schwed., 144, 1826. Carbonate of Cerium. Carbocérine *Beud.*, Tr., **2**, 354, 1832. Lanthanit *Haid.*, Handb., 500, 1845. Hydrolanthanit *Glocker*, Synops., 248, 1847.

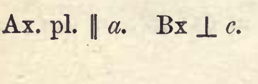
Orthorhombic. Axes: $\breve{a} : \bar{b} : \dot{c}$ = 0·9528 : 1 : 0·9023 Lang[1].

100 ∧ 110 = *43° 37′, 001 ∧ 101 = 43° 26½′, 001 ∧ 011 = 42° 3½′.

**Forms**: *a* (100, *i-ī*), *c* (001, *O*); *m* (110, *I*); *o* (111, 1).

Angles: *mm'''* = 87° 14′, *oo'* = 70° 13′, *oo''* 105° 12′, *oo'''* = 66° 28′, *oo*$^{iv}$ = *74° 48′.

In thin four-sided plates or minute tables ∥ *c*, with beveled edges. Also fine granular or earthy.



Cleavage: micaceous ∥ *c*. H. = 2·5–3. G. = 2·605 Genth; 2·666 (?) Blake. Luster pearly or dull. Color grayish white, delicate pink, or yellowish. Optically —. Ax. pl. ∥ *a*. Bx ⊥ *c*. Dispersion $\rho < v$ small. Axial angles:

$2E_r = 108° 1'$ $2E_{bl} = 108° 39'$ Dx.[2]

**Comp.**—Hydrous lanthanum carbonate, $La_2(CO_3)_3 + 9H_2O$ = Carbon dioxide 21·4, lanthanum trioxide 52·4, water 26·2 = 100.

Analyses, see 5th Ed., p. 710. Didymium is present with the lanthanum.

**Pyr., etc.**—In the closed tube yields water. B.B. infusible; but whitens and becomes opaque, silvery, and brownish; with borax, a glass, slightly bluish, reddish, or amethystine, on cooling; with salt of phosphorus a glass, bluish amethystine while hot, red when cold, the bead becoming opaque when but slightly heated, and retaining a pink color. Effervesces in acids.

**Obs.**—Found coating cerite at Bastnäs, Sweden; also in Silurian limestone with the zinc ores of the Saucon valley, Lehigh Co., Pa., in masses consisting of aggregated minute tables, very rare; at the Sandford iron-ore bed, Moriah, Essex Co., N. Y., in delicate scales, and a thin scaly crust, in fissures in the ore, and on crystals of allanite.

**Ref.**—[1] Phil. Mag., **25**, 43, 1863; cf. also Blake, Am. J. Sc., **16**, 228, 1853. [2] Min., **2**, 177, 1874.

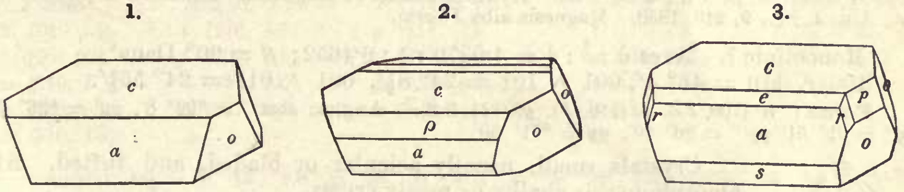
HYDROCONITE. Hydroconit *Hausm.*, Handb., **2**, 1405, 1847. A hydrous calcium carbonate, $CaCO_3 + 5H_2O$. It was formed artificially by Pelouze (Ann. Ch. Phys., **48**, 301, 1831), and noted as a recent formation in a water pipe by Salm-Horstmar (Pogg., **35**, 515, 1835), and as a deposit from a brook near Christiania, Norway, by Scheerer (ib., **68**, 381, 1846). It is described as occurring in acute colorless rhombohedrons with G. = 1·75; prismatic crystals obtained by Becquerel (Ann. Ch. Phys., **47**, 5, 1831) are also mentioned, and dimorphism suggested.

**299. TRONA.** Trona *Bagge*, Ak. H. Stockh., **35**, 140, 1773. Natrum von Tripole, Stralige Natrum, *Klaproth*, Beitr., **3**, 83, 1802. Urao *Boussingault*, Ann. Mines, **12**, 278, 1826.

Monoclinic. Axes: $\grave{a} : \overset{\scriptscriptstyle 1}{b} : \grave{c} = 2·8460 : 1 : 2·9697$; $\beta = {}^*77° 23' = 001 \wedge 100$ Zepharovich.

$100 \wedge 110 = 70° 11\frac{5}{6}'$, $001 \wedge 101 = 39° 40'$, $001 \wedge 011 = 70° 57\frac{3}{4}'$.

**Forms**[1]: $\rho$ (304, $-\frac{3}{4}$-ī) $\beta$ ($\bar{1}$·0·18, $\frac{1}{18}$-ī) $s$ ($\bar{3}$02, $\frac{3}{2}$-ī) $r$ (211, $-$ 2-$\bar{2}$)[2]
$a$ (100, $i$-ī) $e$ (101, $-$ 1-ī)[2] $\gamma$ ($\bar{2}$·0·13, $\frac{2}{13}$-ī) $p$ (111, $-$ 1)[2] $o$ ($\bar{1}$11, 1)
$c$ (001, $O$)



Figs. 1, 2, Zepharovich. 3, Ayres.

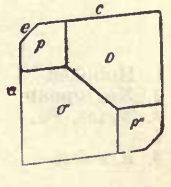
$oo'' = {}^*47° 35\frac{1}{2}'$

$ar = 52° 59'$
$ap = 67° 34\frac{1}{2}'$
$a'o = {}^*74° 54'$

Crystals elongated ∥ axis $\overset{\scriptscriptstyle 1}{b}$, also flattened ∥ $c$. Faces in the orthodome zone striated horizontally. Often fibrous or columnar massive.



Cleavage: $a$ perfect; $o$, $c$ in traces. Fracture uneven to subconchoidal. H. = 2·5–3. G. = 2·11–2·14. Luster vitreous, glistening. Color gray or yellowish white. Translucent. Taste alkaline. Not altered by exposure to a dry atmosphere. Optically $-$. Ax. pl. and $Bx_a \perp b$; $Bx_o \wedge \grave{c} = 83° 6'$ Zeph. Dispersion $\rho < v$ small. Axial angles:

$2H_{a.r} = 78° 43'$ $2H_{o.r} = 107°$ $\therefore$ $2E_r = 136° 46'$ $\beta_r = 1·500$ Dx.[1]
$2H_{a.bl} = 79° \ 1'$ $2H_{o.bl} = 106° 50'$ $\therefore$ $2E_{bl} = 140° 12'$ $\beta_{bl} = 1·514$ Dx.
$2H_{a.y} = 73° 25'$ $2H_{o.y} = 99° 17\frac{1}{2}'$ $\therefore$ $2E_y = 137° 7'$ $2V_y = 76° 16'$ $\beta_y = 1·507$ Z.

**Comp.**—$Na_2CO_3.HNaCO_3 + 2H_2O$ or $3Na_2O.4CO_2.5H_2O$ = Carbon dioxide 38·9, soda 41·2, water 19·9 = 100, Chatard.

**Anal.**—1, Boussingault, l. c. 2, Reinitzer, Zs. Kr., **13**, 138, 1887. 3, T. M. Chatard, Am. J. Sc., **38**, 59, 1889, also other anals. on salts obtained by the evaporation of the water of Owen's Lake, and on artif. compounds.

| | | $CO_2$ | $Na_2O$ | $H_2O$ |
|---|---|---|---|---|
| 1. *Urao* | | 39·00 | 41·22 | 18·80 = 99·02 |
| 2. *Trona* | | 38·93 | 40·77 | 19·96 $Na_2SO_4$ 0·20 = 99·86 |
| 3. Owen's Lake | G. = 2·147 | 38·13 | 41·00 | 20·07 Cl 0·19, $SO_3$ 0·70, insol. 0·02 = 100·11. |

Chatard establishes the above composition for urao, and shows that trona, sometimes called "sesquicarbonate of soda," is an impure form of the same compound; he also shows the variation which may come from the admixture of other carbonates (cf. l. c., and Natural Soda, its occurrence and utilization, Bull. **60**, U. S. G. Surv., 1887–88).

**Pyr., etc.**—In the closed tube yields water and carbon dioxide. B.B. imparts an intensely yellow color to the flame. Soluble in water, and effervesces with acids. Reacts alkaline with moistened test paper.

**Obs.**—Found in the province of Fezzan, Africa, forming thin superficial crusts at numerous points especially in connection with certain salt lakes. Urao is found at the bottom of a lake at Lagunilla, Venezuela, S. A., a day's journey from Merida. Also near soda lakes at other localities.

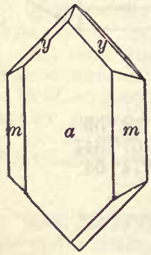
Efflorescences of trona occur near the Sweetwater river, Rocky Mountains, mixed with sodium sulphate and common salt. An extensive bed in Churchill Co., Nevada. In fine crystals at Borax lake, San Bernardino Co., California, with hanksite, glauberite, thenardite, etc.; also formed by the spontaneous evaporation of the saline waters of Owen's Lake, Inyo Co., Cal. (Cf. Chatard. l. c.).

**Ref.**—[1] On artif. cryst., Zs. Kr., **13**, 135, 1887; for earlier measurements cf. Haid., Ed. J. Sc., **2**, 325, 1825, or Pogg., **5**, 367, 1825. Dx., who makes $o = m$ (110), etc., adds two domes perhaps 407, $\bar{2}09$ (Z.), N. R., 182, 1867, Min., **2**, 169, 1874. [2] E. F. Ayres, Am. J. Sc., **38**, 65, 1889.

**300. HYDROMAGNESITE.** *T. Wachtmeister*, Ak. H. Stockh., 18, 1827. Hydromagnesit *v. Kobell*, J. pr. Ch., **4**, 80, 1835. Hydrocarbonate of Magnesia. Lancasterite pt. *Silliman, Jr.*, Am. J. Sc., **9**, 216, 1850. Magnesia alba *Pharm.*

Monoclinic ?. Axes $\grave{a} : \bar{b} : \dot{c} = 1·0379 : 1 : 0·4652$; $\beta = 90°$ Dana[1].
$100 \wedge 110 = 46° 4'$, $001 \wedge 101 = 24° 8\frac{1}{2}'$, $001 \wedge 011 = 24° 56\frac{5}{6}'$.

**Forms:** *a* (100, $i$-$\bar{i}$), *m* (110, *I*), *y* (121, 2-$\grave{2}$). Angles: $mm''' = *92° 8'$, $yy' = *36° 20'$, $yy'' = 91° 51'$ $yy''' = 80° 40'$, $ay = *71° 50'$.



Crystals small, usually acicular or bladed, and tufted. Also amorphous; as chalky or mealy crusts.

Brittle. H. = 3·5 cryst. G. = 2·145–2·18 S. & B. Luster vitreous to silky or subpearly; also earthy. Color and streak white.

**Comp.**—Basic magnesium carbonate, $3MgCO_3.Mg(OH)_2 + 3H_2O$ or $4MgO.3CO_2.4H_2O$ = Carbon dioxide 36·3, magnesia 43·9, water 19·8 = 100.

**Anal.**—1, Wachtmeister, l. c. 2, v. Kobell, l. c. 3. 4, Smith & Brush, of crystalline varieties, Am. J. Sc., **15**, 214, 1853. 5, Tschermak, Min. Mitth., 113, 1871.

| | | $CO_2$ | $MgO$ | $H_2O$ |
|---|---|---|---|---|
| 1. Hoboken | | 36·82 | 42·41 | 18·53 $SiO_2$ 0·57, $Fe_2O_3$ 0·27, earthy matter [1·39 = 99·99 |
| 2. Negroponte | | 36·00 | 43·96 | 19·68 $SiO_2$ 0·36 = 100 |
| 3. Texas, Pa. | G. = 2·16 | 36·69 | 43·20 | 19·83 Fe and Mn *tr.* = 99·72 |
| 4. " | | 36·74 | 42·30 | 20·10 Fe and Mn *tr.* = 99·14 |
| 5. Kraubat | | 35·71 | 44·02 | 19·74 insol. 0·99 = 100·46 |

**Pyr., etc.**—In the closed tube gives off water and carbon dioxide. B.B. infusible, but whitens, and the assay reacts alkaline to turmeric paper. Soluble in acids; the crystalline compact varieties are but slowly acted upon by cold acid, but dissolve with effervescence in hot acid.

**Obs.**—Occurs at Hrubschitz, in Moravia, in serpentine; also in acicular crystals in serpentine at Kraubat, Styria; in Negroponte, near Kumi; at Kaiserstuhl, in Baden, impure. In the

U. S., crystallized, with serpentine and brucite, near Texas, Lancaster Co., Penn., at Wood's and Low's mines; also in a similar way at Hoboken, N. J., in acicular crystals, and in earthy crusts. The brucite of Hoboken sometimes changes on exposure to an earthy hydromagnesite.

The *lancasterite* of Silliman (l. c.) is shown by Smith and Brush to be a mixture of brucite and hydromagnesite.

Pseudomorphs after brucite occur at Wood's mine.

**Ref.**—[1] Made monoclinic by J. D. D. (Am. J. Sc., **17**, 84, 1854), but the author's measurements make the variation from the orthorhombic type at least very small; this confirms Tschermak's optical results (l. c.).

**301. HYDROGIOBERTITE.** Idrogiobertite *E. Scacchi*, Rend. Accad. Sc., Napoli, Dec. 12, 1885.

In spherical forms, 2 to 15 mm. in diameter; compact. G. = 2·149–2·174. Color light gray.

**Comp.**—$MgCO_3.Mg(OH)_2 + 2H_2O$ or $2MgO.CO_2.3H_2O$ = Carbon dioxide 24·7, magnesia 44·9, $H_2O$ 30·4 = 100.

**Anal.**—1, 2, E. Scacchi, both calculated to 100 after deducting impurities.

| | $CO_2$ | MgO | $H_2O$ | | |
|---|---|---|---|---|---|
| 1. | 25·16 | 44·91 | 29·93 | = | 100 |
| 2. | 25·29 | 44·28 | 30·43 | = | 100 |

**Obs.**—Found in an augitophyre from the neighborhood of Pollena, Italy; magnetite is often embedded in the mineral.

**302. LANSFORDITE.** *F. A. Genth*, Zs. Kr., **14**, 255, 1888. *F. A. Genth* and *S. L. Penfield*, Am. J. Sc., **39**, 121, 1890.

Triclinic. Axes $\breve{a} : \bar{b} : \grave{c} = 0·5493 : 1 : 0·5655$; $\alpha = 95° 21\frac{2}{3}'$; $\beta = 100° 15'$, $\gamma = 92° 27\frac{1}{2}'$ Penfield.

$100 \wedge 010 = 86° 31'$, $100 \wedge 001 = 79° 27\frac{2}{3}'$, $010 \wedge 001 = *84° 6'$.

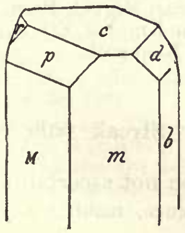
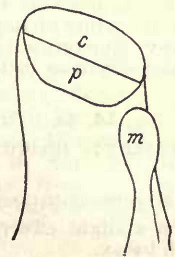
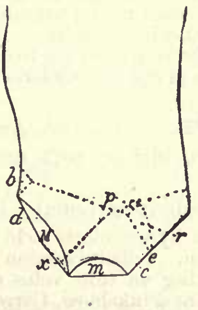
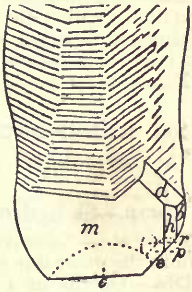
Angles: *cm* = 78° 12', *cM'* = *96° 35', *mM'* = *56° 57', *bM'* = *64° 13', *bd* = *39° 16', *cd* = 44° 50', *cp* = 44° 59', *ap* = 42° 40½'. For other angles, see Pfd.

In stalactitic forms, bounded at the free extremity with crystalline faces.









Cleavage: distinct, probably ‖ *c*. H. = 2·5. G. = 1·54 Stackhouse; 1·692 Keeley. Luster on original crystalline faces vitreous. White and translucent, resembling paraffin, when unaltered, but speedily becoming dull white and opaque.

**Comp.**—$3MgCO_3.Mg(OH)_2 + 21H_2O$ = Carbon dioxide 19·2, magnesia 23·2, water 57·6 = 100.

**Anal.**—F. J. Keeley, Zs. Kr., **14**, 255, 1888.

| $CO_2$ 18·90 | MgO 23·18 | $H_2O$ 57·79 = 99·87 |
|---|---|---|

Of the water 26·33 p. c. are lost over $H_2SO_4$, 12·31 p. c. at 110° C., 9·76 at 185° C., 9·39 at a red heat. Stackhouse (ib.) obtained: $CO_2 + H_2O$ [76·40], MgO 23·60 = 100.

**Obs.**—When first found, formed small stalactites (up to 20 mm. in length) attached to the carbonaceous shale forming the roof of a gallery in the anthracite mine at Nesquehoning near Lansford, Schuylkill Co., Penn. These were in part changed to nesquehonite (p. 300), and later when exposed to the exterior air the change became complete and they were converted into a white chalky mass showing dull crystalline planes at the extremity.

HYDRODOLOMITE. Hydromagnesit *v. Kobell*, J. pr. Ch., **36**, 304, 1845. Kalkmagnesit *Hausm.*, Handb., 1404, 1847. Hydromanganocalcit *Hartmann*, Nachr., 299. Hydromagnocalcit pt. Hydrodolomit *Rg.* Hydronickelmagnesite *Shep.*, Am. J. Sc., **6**, 250, 1848. Pennite *Herm.*, J. pr. Ch., **47**, 13, 1849.

This includes the *hydrodolomite* of Vesuvius, which is stalactitic and in globular forms; G. = 2·495; white or yellowish white. Also *pennite* of Hermann, from Texas, Pa., which occurs in apple-green to whitish crusts, having a surface of minute spherules, on serpentine and chromite: the color is due to nickel; a substance called pennite also occurs at Swinaness and Haroldswick, Unst, Shetland.

Analyses (see 5th Ed., p. 708) show hydrodolomite to be a hydrated carbonate of calcium and magnesium, but probably a mixture of hydromagnesite and calcite. Genth states that pennite is dolomite in minute hexagonal prisms, generally coated with deweylite, etc., so that the crystals can rarely be recognized.

HIBBERTITE *Heddle*, Min. Mag., **2**, 24, 1878. A pulverulent, lemon-yellow substance occurring with chromite on the island of Unst. It is a hydrous carbonate of magnesium and calcium, probably a mixture like the above. See 5th Ed., App. III, p. 58. Named after the discoverer of chromite on Unst.

**303. ZARATITE.** Hydrate of Nickel (fr. Texas, Pa.) *Silliman, Jr.*, Am. J. Sc., **3**, 407, 1847; Emerald Nickel *Id.*, ib., **6**, 248, 1848. Nickel Smaragd *Germ.* Texasit *Kenng.*, Min., 1853. Carbonato hidratado de Niquel (fr. Spain) *A. Casares*, A. M. Alcibar in Min. Revista of Madrid, 304, 1850; Zaratita *Casares*, ib., 176, March, 1851. Zamtit *wrong orthogr.*

Incrusting; often small stalactitic or minute mammillary; sometimes appearing prismatic with rounded summits. Also massive, compact.

Brittle. H. = 3–3·25. G. = 2·57–2·69. Luster vitreous. Color emerald-green. Streak paler. Transparent to translucent.

**Comp.**—A hydrated basic nickel carbonate, $NiCO_3.2Ni(OH)_2 + 4H_2O$ or $3NiO.CO_2.6H_2O$ = Carbon dioxide 11·7, nickel protoxide 59·6, water 28·7 = 100.

Analyses, 5th Ed., p. 711.

**Pyr., etc.**—In the closed tube yields water and carbon dioxide, and leaves a grayish black magnetic residue. B.B. infusible. With borax reacts for nickel. Dissolves easily with effervescence in heated dilute hydrochloric acid.

**Obs.**—Occurs on chromite at Texas, Lancaster Co., Pa., associated with serpentine; also at Swinaness, Unst, Shetland.

Also in Spain, near Cape Hortegal in Galicia, where it occurs as an incrustation on a magnetite in which there is some nickel sulphide; it is in clear emerald-green, vitreous crusts, sometimes transparent, and also in stalactites. From the mines of Rapi, San Miguel, Peru. In a chromite mine with millerite in peridotyte from the Sommergraben near Kraubat, Styria.

Named after Sen. Zarate of Spain. Casares's name antedates that of Kenngott.

**304. REMINGTONITE.** *J. C. Booth*, Am. J. Sc., **14**, 48, 1852.

A rose-colored incrustation, soft and earthy; opaque. Streak pale rose-colored.

**Comp.**—A hydrous cobalt carbonate, but precise composition not ascertained.

**Pyr., etc.**—Dissolves in hydrochloric acid with a slight effervescence, making a green solution, the color due to iron. Cobalt reaction with borax.

**Obs.**—Occurs as a coating on thin veins of serpentine, which traverse hornblende and epidote, at a copper mine near Finksburg, Carroll Co., Maryland. Named for Edward Remington, superintendent of the mine at which it was found.

**305. TENGERITE.** Kolsyrad Ytterjord *A. F. Svanberg* and *C. Tenger*, Årsb., **16**, 206, 1838. Tengerite *Dana.* Carbonyttrine *Adam*, Tabl. Min., 24, 1869.

Pulverulent. In thin coatings. Sometimes an appearance of radiated crystallization.

Luster dull, or like that of chalk. Color white.

**Comp.**—Stated to be an yttrium carbonate, but no analysis has been published.

**Pyr., etc.**—In the closed tube yields a considerable amount of water (Brush). Effervesces with acids.

**Obs.**—Occurs as a thin coating on gadolinite at Ytterby, and is evidently a result of its alteration. A similar mineral, sometimes in crystals, is associated with the gadolinite of Llano Co., Texas, but it has not been positively identified.

**306. BISMUTITE.** Bismutit *Breith.*, Pogg., **53**, 627, 1841. Kohlensaures Wismuthoxyd, Wismuthspath, *Germ.* Bismuthite. Carbonate of Bismuth.

Incrusting, or earthy and pulverulent; amorphous.

H. = 4–4·5. G. = 6·86–6·9 Breith.; 7·67 Rg. Luster vitreous when pure; sometimes dull. Color white, mountain-green, and dirty siskin-green; occasionally straw-yellow and yellowish gray. Streak greenish gray to colorless. Subtranslucent to opaque.

**Comp.**—A basic bismuth carbonate, exact composition doubtful, perhaps $Bi_2O_3.CO_2.H_2O$ (Louis, anal. 4). Cf. bismutosphärite, p. 290.

**Anal.**—1, Rg., Pogg., **76**, 564, 1849. 2, 3, Genth, Am. J. Sc., **23**, 426, 1857. 4, Louis, Min. Mag., **7**, 139, 1887.

| | | | $CO_2$ | $Bi_2O_3$ | $H_2O$ | |
|---|---|---|---|---|---|---|
| 1. | Chesterfield Distr. | G. = 7·67 | 6·56 | 90·00 | 3·44 | = 100 |
| 2. | " " | | 7·04 | 89·05 | 3·91 | = 100 |
| 3. | " " | | 7·30 | 87·67 | 5·03 | = 100 |
| 4. | Transvaal | | 8·04 | 88·95 | 3·00 | = 100 |

The material in most cases is very impure; from the above analyses iron oxide, silica, etc., have been deducted, e.g., in 1, 7 p. c.; in 4, 10·5 p. c., G. = 6·86 of the impure material.

Carnot obtained in bismuth carbonates from Meymac, Corrèze, France, with G. = 6·9–7·6: 86·9–89·7 p. c. $Bi_2O_3$, 3·14–6·43 $CO_2$, 1·94–4·86 $H_2O$, C.R., **79**, 304, 1874. Cf. also analyses by Frenzel, Liversidge, Winkler, 5th Ed., App. III, p. 16.

**Pyr., etc.**—In the closed tube decrepitates and gives off water. B.B. fuses readily, and on charcoal is reduced to bismuth, and coats the coal with yellow bismuth oxide. Dissolves in nitric acid, with slight effervescence. Dissolves in hydrochloric acid, affording a deep yellow solution.

**Obs.**—Bismutite occurs at Schneeberg and Johanngeorgenstadt, with native bismuth, and near Hirschberg in Russian Voigtland, with brown iron ore, native bismuth, and bismuthinite; at Joachimsthal; Neustädtel, Saxony; near Baden. At Meymac, Corrèze, France; with auriferous quartz in the Lydenburg district of the Transvaal. In New South Wales, at Pond's Creek with stream tin.

In the U. S., in So. Carolina, at Brewer's mine, in porous yellowish masses, sometimes reddish from iron oxide; surface of fracture white and vitreous, resembling somewhat calamine; in Gaston Co., N. C., in yellowish white concretions. In California, in gold placers on Big Pine Creek, Inyo Co.; also from Phœnix, Arizona.

WALTHÉRITE *Adam*, Tabl. Min., 27, 1869. A bismuth carbonate occurring with the bismutite of Joachimsthal in thin longish crystals, vitreous siskin-green to clove-brown, translucent. It contains, according to Lindacker (Vogl's Min. Joach., 168), bismuth oxide, carbon dioxide, water, silica; effervesces with acids, and B.B. gives bismuth reactions. Cf. Btd., Bull. Soc. Min., 4 58, 1881.

AGNESITE. Carbonate of Bismuth *W. Macgregor*, Sowerby's English Min., *Beud.*, Tr., 2, 375, 1832; Agnesite *B. & M.* Min., 591, 1852. Gregorite *Adam*, Tabl. Min., 27, 1869. An earthy steatite-like mineral from St. Agnes in Cornwall, made by Macgregor a bismuth carbonate, but his results have been shown to be totally erroneous. See further 5th Ed., p. 793.

**307. URANOTHALLITE.** Kalk-Uran-carbonat *Vogl.* Jb. G. Reichs., **4**, 221, 1853. Flutherite *Weisbach*. Synops. Min., 48, 1875. Uranothallit *Schrauf*, Zs. Kr., **6**, 410, 1882.

Orthorhombic. Axes $\breve{a} : \bar{b} : \acute{c}$ = 0·601 : 1 : 0·358 (approx.) Schrauf[1].

**Forms:** *b* (010, *i*-ĭ), *m* (110, *I*), *n* (130, *i*-3̆), *u* (201, 2-ī), *o* (221, 2), *φ* (263, 2-3̆).
Measured angles: *mm‴* = 60°–63°, *um* = 47°–49°, *mφ* = 56° 40′, *φo* = 25°–26°.

Crystals minute and indistinct, united in scaly or granular aggregates, often incrusting.

Cleavage: *a* (100) easy but imperfect. H. = 2·5–3·0. Luster vitreous, on cleavage-face pearly. Color siskin-green. Streak same but paler. Subtransparent to translucent.

**Comp.**—$2CaCO_3.U(CO_3)_2.10H_2O$ or $2CaO.UO_2.4CO_2.10H_2O$ = Carbon dioxide 23·8, uranium dioxide 36·8, lime 15·1, water 24·3 = 100.

**Anal.**—1, Lindacker, Jb. G. Reichs., **4**, 221, 1853. 2, Schrauf, l. c. 3, Foullon, Vh. G. Reichs., 269, 1883.

| | $CO_2$ | $UO_2$ | CaO | $H_2O$ |
|---|---|---|---|---|
| 1. | $\frac{8}{3}$ 24·18 | 37·03 | 15·55 | 23·24 = 100 |
| 2. | 22·95 | 36·29 | 16·42 | 23·72 = 99·38 |
| 3. | 23·13 | 35·45 | 16·28 | 22·44 FeO 2·48 = 99·78 |

**Pyr.**—B.B. on charcoal infusible; with borax and salt of phosphorus the reaction for uranium. Dissolves with effervescence in sulphuric acid, a white deposit being thrown down; solution in sulphuric and hydrochloric acids green, in nitric acid yellow.

**Obs.**—Occurs as an incrustation on uraninite at Joachimsthal, Bohemia.

**Ref.**—[1] L. c., cf. Brz., Vh. G. Reichs., 269, 1883.

308. **LIEBIGITE.** *J. L. Smith*, Am. J. Sc., **5**, 336, 1848, and **11**, 259, 1851. Uran-Kalk-Carbonat *Vogl*, Jb. G. Reichs., **4**, 221, 1853.

In mammillary concretions, or thin coatings; cleavage apparent in one direction.

H. = 2–2·5. Luster of fracture vitreous. Color beautiful apple-green. Transparent.

**Comp.**—A hydrous carbonate of uranium and calcium, formula perhaps $CaCO_3.(UO_2)CO_3.20H_2O$ (Rg.) = Carbon dioxide 11·1, uranium trioxide 36·4, lime 7·1, water 45·5 = 100.

**Anal.**—J. L. Smith:

| $CO_2$ | $UO_3$ | CaO | $H_2O$ |
|---|---|---|---|
| 10·2 | 38·0 | 8·0 | 45·2 = 101·4 |

**Pyr., etc.**—In a matrass yields much water and becomes yellowish gray. At redness it blackens, without fusing, and on cooling returns to an orange-red color. At a higher heat it blackens, and remains so on cooling. With borax or salt of phosphorus reacts for uranium. Dissolves readily in dilute acids with effervescence.

**Obs.**—Occurs with medjidite on uraninite near Adrianople, Turkey; also at Johanngeorgenstadt and Joachimsthal. Dr. Smith states that both the lime and uranium of this salt are derived from the uraninite. Named for Baron Justus Liebig (1803–1873), the German chemist.

309. **VOGLITE.** Uran-Kalk-Kupfer-Carbonat *Vogl*, Jb. G. Reichs., **4**, 222, 1853. Voglit *Haid.*, ib., 223.

In aggregations of crystalline scales. Scales rhomboidal somewhat like gypsum, with angles of 100° and 80°, Haid.

Luster pearly. Color emerald-green to bright grass-green. Dichroic.

**Comp.**—A hydrous carbonate of uranium, calcium and copper.

**Anal.**—Lindacker, ibid.

| $CO_2$ | UO | CaO | CuO | $H_2O$ |
|---|---|---|---|---|
| 26·41 | 37·00 | 14·09 | 8·40 | 13·90 = 99·80 |

**Pyr., etc.**—In the closed tube blackens and yields water. B.B. in the platinum forceps infusible, colors the flame deep green; if moistened with hydrochloric acid the flame is momentarily blue. With soda on charcoal yields metallic copper. With borax in O.F. the bead is yellow while hot and reddish brown on cooling; in R.F. green while hot and clouded when cold. Soluble in acids with effervescence.

**Obs.**—From the Elias mine, near Joachimsthal, implanted on uraninite.

SCHRÖCKINGERITE *Schrauf*, Min. Mitth., 137, 1873.

Occurs at Joachimsthal on uraninite, in small, six-sided tabular crystals referred to the orthorhombic system; *bm* = 58½°. A bisectrix is normal to *b*. Color greenish to yellow. It is stated to be hydrous oxycarbonate of uranium, containing only traces of $SO_3$. Loss by ignition ($H_2O$ and $CO_2$) = 36·7. Contains also a little lime. Named after Baron Schröckinger.

**RANDITE** *Koenig*, Proc. Ac. Philad., 408, 1878. A canary-yellow incrustation on granite, at Frankford, near Philadelphia, Penn. A hydrous carbonate of calcium and uranium. An analysis (on 0·047 gr.) of impure material: [$CO_2$ 29·34], $U_2O_3$ 31·63, CaO 32·50, $H_2O$ 6·53 = 100. T. D. Rand (ib., 274, 1880) shows that the coating consists largely of calcite, and after this has been removed by acetic acid, there remain the unattacked tufts of acicular crystals of randite; these, dissolved in hydrochloric acid, yielded largely of calcium and uranium, with a trace of phosphoric acid, alumina, etc.

**SELBITE.** Luftsaures Silber (from anal. by Selb) *Widenmann*, Min., 689, 1794, *Lenz*, Min., 95, 1794; Grausilber; Carbonate of Silver, *Selb*, Tasch. Min., **9**, 394, 1817; Selbit *Haid.*, Handb., 506, 1845. A grayish ore, made a carbonate by Selb, who discovered it, in 1788, at the mine Wenzel near Wolfach, Baden. According to Walchner (Mag. f. Pharm., **25**, 1) it is only a mixture; and, according to Sandberger (Jb. Min., 221, 1864), one of Selb's original specimens, under the lens, proved to contain within earthy argentite, dolomite and silver, and all parts afforded a sulphur reaction.

Del Rio described a silver carbonate from Real Catorce, Mexico, where it is called *Plata Azul* (Gilb. Ann., **71**, 11, 1822), which also is regarded as a mixture. Plata azul, however, is a term somewhat loosely used for a number of silver ores. Cf. Domeyko, Min. Chili, 420, 1879.

# Oxygen Salts.

## 2. SILICATES.

### A. Anhydrous Silicates.

### B. Hydrous Silicates.

This chapter closes with a section including the Titanates, Silico-titanates, Titano-niobates, etc., which connect the Silicates proper with the Niobates and Tantalates.

The line between the strictly anhydrous and hydrous silicates cannot be sharply drawn, since with many species which yield water upon ignition, the part played by the elements forming the water is as yet uncertain. Furthermore, in the cases of several groups the strict arrangement is deviated from, since the relation of the species is best exhibited by introducing the related hydrous species immediately after the others.

---

### A. Anhydrous Silicates.

Some species strictly belonging here are placed among the Hydrous Silicates; see p. 563.

**I. Disilicates, Polysilicates.**
**II. Metasilicates.**
**III. Orthosilicates.**
**IV. Subsilicates.**

The Disilicates, $RSi_2O_5$, are salts of disilicic acid, $H_2Si_2O_5$, and have an oxygen ratio of silicon to bases of 4 : 1, as seen when the formula is written after the dualistic method, $RO.2SiO_2$.

The Polysilicates, $R_2Si_3O_8$, are salts of polysilicic acid, $H_4Si_3O_8$, and have an oxygen ratio of 3 : 1, as seen in $2RO.3SiO_2$. They have been called *trisilicates.*

The Metasilicates, $RSiO_3$, are salts of metasilicic acid, $H_2SiO_3$, and have an oxygen ratio of 2 : 1. They have hence been called *bisilicates.*

The Orthosilicates, $R_2SiO_4$, are salts of orthosilicic acid, $H_4SiO_4$, and have an oxygen ratio of 1 : 1. They have hence been called *unisilicates.* The majority of the silicates fall into one of the last two groups.

Furthermore, there are a number of species characterized by an oxygen ratio of less than 1 : 1, e.g., 3 : 4, 2 : 3, etc. These basic species are grouped as Subsilicates. Their true position is often in doubt; in some cases they are to be regarded as basic salts belonging to one of the other groups.

The above classification cannot, however, be carried through strictly. since there are many species which do not exactly conform to any one of the groups named, and often the true interpretation of the composition is doubtful. Furthermore, within the limits of a single group of species, connected closely in all essential characters, there may be a wide variation in the proportion of the acidic element. Thus the triclinic feldspars, placed among the polysilicates, range from the true polysilicate, $NaAlSi_3O_8$, to the orthosilicate, $CaAl_2Si_2O_8$, with many intermediate compounds, regarded as isomorphous compounds of these extremes. Similarly of the scapolite group, which, however, is included among the orthosilicates, since the majority of the compounds observed approximate to that type. The micas form another example. For a further discussion of the matter see the special groups in the pages which follow.

It is possible to reduce the number of acids assumed, as suggested by Groth, by regarding polysilicic acid as compounded of disilicic and metasilicic acids, $H_4Si_3O_8 = H_2Si_2O_5 + H_2SiO_3$. Or, as suggested by Becker, metasilicic acid may be regarded as formed from polysilicic acid and orthosilicic acid, $4H_2SiO_3 = H_4Si_3O_8 + H_4SiO_4$; while disilicic acid may be considered as a polysilicic acid from which orthosilicic acid has been isolated, $4H_2Si_2O_5 = 3H_4Si_3O_8 - H_4SiO_4$. Rammelsberg prefers to regard most of the more complex silicates, not conforming to the simple types, as compounds in varying proportions of metasilicates and orthosilicates, with sometimes disilicates, etc.

An excellent recent discussion of the composition of the Silicates as a whole is given by Groth in the last edition (1889) of his *Tabellarische Uebersicht der Mineralien*, pp. 87–102. Brief but suggestive remarks are made by Tschermak in his *Lehrbuch der Mineralogie* (1883). Important recent contributions to the subject have been made by F. W. Clarke, who has discussed the matter from a more or less theoretical standpoint (Am. J. Sc., **29**, 382, 1885, **31**, 270, 1886, **38**, 384, 1889, *et al.*) and also attacked the problem by analytical methods (ib., **40**, 303, 405, 452, 1890) with important results. Cf. also Id., U. S. G. Surv., Bull., **60**, 13, 1890, **78**, 11, 1891.

---

## I. Disilicates, $RSi_2O_5$. Polysilicates, $R_2Si_3O_8$.

### Petalite Group.

| | | | | $\grave{a} : \grave{\bar{b}} : \grave{c}$ | $\beta$ |
|---|---|---|---|---|---|
| **310.** | **Petalite** | $LiAl(Si_2O_5)_2$ | Monoclinic | 1·1534 : 1 : 0·7436 | 67° 34′ |
| **311.** | **Milarite** | $HKCa_2Al_2(Si_2O_5)_6$ | Hexagonal | $\grave{c}$ = 0·6620 | |

| | | | | $\grave{a} : \grave{\bar{b}} : \grave{c}$ | $\beta$ |
|---|---|---|---|---|---|
| **312.** | **Eudidymite** | $HNaBeSi_3O_8$ | Monoclinic | 1·7107 : 1 : 1·1071 | 86° 14½′ |

**310. PETALITE.** Petalit *d'Andrada*, Scherer's J., **4**, 36, 1800. Castor (fr. Elba) *Breith.*, Lieb. Ann., **69**, 436, 1849. Berzeliite *Clarke*, Ann. Phil., **11**, 196, 1818.

Monoclinic. Axes: $\grave{a} : \grave{\bar{b}} : \grave{c} = 1·1534 : 1 : 0·7436$; $\beta = {}^*67° 34' = 001 \wedge 100$ Des Cloizeaux[1].

$100 \wedge 110 = 46° 50'$, $001 \wedge 101 = 25° 33\frac{1}{2}'$, $001 \wedge 011 = 34° 30\frac{1}{6}'$.

**Forms**[1]:
*a* (100, *i*-$\bar{i}$)
*b* (010, *i*-$\grave{i}$)
*c* (001, *O*)
*m* (110, *I*)
*g* (120, *i*-$\grave{2}$)
*y* (101, − 1-$\bar{i}$)
*ω* (403, − $\frac{4}{3}$-$\bar{i}$)
*o* (201, − 2-$\bar{i}$)
*z* ($\bar{9}05$, $\frac{9}{5}$-$\bar{i}$)? cleavage
*α* ($\bar{4}01$, 4-$\bar{i}$)
*e* (021, 2-$\grave{i}$)
*x* ($\bar{2}41$, 4-$\grave{2}$)

$mm''' = 93° 40'$
$bm = {}^*43° 10'$
$gg' = 50° 15'$
$c\omega = 30° 53\frac{1}{2}'$
$co = {}^*38° 37'$
$cz = 62° 33'$
$c\alpha = 89° 37'$
$ce = 53° 58'$
$cm = 74° 52'$
$cx = 80° 23'$
$xx' = 129° 32'$
$mo = 53° 14'$

The form of petalite approximates to that of the monoclinic pyroxenes, especially to spodumene; in composition also these two species are related, but in specific gravity they diverge widely.

Crystals rare, commonly tabular ∥ *b* or elongated ∥ $\grave{a}$; the faces *c*, *a*, *o* smooth, the others often striated or rough. Usually massive, foliated cleavable.

Cleavage: *c* perfect; *o* (201) easy, *z* ($\bar{9}05$) difficult and imperfect. Fracture imperfectly conchoidal. Brittle. H. = 6–6·5. G. = 2·39–2·46. Luster vitreous, on *c* pearly. Colorless, white, gray, occasionally reddish or greenish white. Streak uncolored. Transparent to translucent.

Optically +. Double refraction strong. Ax. pl. and $Bx_a \perp b$; the ax. pl. inclined $-87° 30'$ to *c* for red, hence $Bx_{o.r} \wedge \dot{c} = -75° 4'$; also $Bx_{o.bl} \wedge \dot{c} = -74° 30'$. Dispersion $\rho < v$ small; crossed, weak. Axial angles, castorite, Dx.[2]

$$2H_{a.r} = 86° 27\tfrac{1}{3}' \quad 2H_{a.y} = 86° 30\tfrac{1}{3}' \quad 2H_{a.bl} = 86° 42' \quad \beta_r = 1·5078 \quad \beta_y = 1·5096 \quad \beta_{bl} = 1·5180$$

$$\therefore \quad 2V_r = 83° 30' \qquad 2V_y = 83° 34' \qquad 2V_{bl} = 83° 52'$$

Also, petalite:

$$2H_{a.r} = 86° 24' \qquad 2H_{a.y} = 86° 28' \qquad 2H_{a.bl} = 86° 43'$$

$$\alpha_y = 1·504 \qquad \beta_y = 1·510 \qquad \gamma_y = 1·516 \text{ M. Lévy-Lcx.}^3$$

**Var.**—1. *Castorite*, in distinct transparent crystals, affording the above angles, Dx. G. = 2·38, Breith.; 2·397–2·405, Damour.

2. *Ordinary petalite*, cleavable massive; G. = 2·412, 2·420, 2·465 Utö, Dmr.

**Comp.**—$LiAl(Si_2O_5)_2$ or $Li_2O.Al_2O_3.8SiO_2$ = Silica 78·4, alumina 16·7, lithia 4·9 = 100.

**Anal.**—1, Sonden, G. För. Förh., **6**, 39, 1882. after deducting 0·5 p. c. apatite. 2, Smith and Brush, Am. J. Sc., **16**, 373, 1853. 3, Rg., Ber. Ak. Berlin, 13, 1878. 4, F. W. Clarke, priv. contr.

| | | $SiO_2$ | $Al_2O_3$ | $Li_2O$ | $Na_2O$ | $K_2O$ | |
|---|---|---|---|---|---|---|---|
| 1. Utö | $\frac{2}{2}$ | 77·97 | 17·08 | 4·22 | 0·73 | — | = 100 [0·24 = 99·75 |
| 2. Bolton | $\frac{2}{2}$ | 77·92 | 16·24 | 3·63 | 0·51 | *tr.* | ign. 0·65, $Fe_2O_3$ 0·56, Mg |

The chemical composition and relation to spodumene are discussed by Doelter, Min. Mitth., **1**, 529, 1878.

**Pyr., etc.**—Gently heated emits a blue phosphorescent light. B.B. on charcoal becomes glassy, subtransparent, and white, and melts only on the edges; gives the reaction for lithia. With borax it forms a clear, colorless glass. Not acted on by acids.

**Obs.**—Petalite occurs at the iron mine of Utö, Sweden, accompanying lepidolite, tourmaline, spodumene, and quartz; on Elba (*castorite*) in attached crystals.

In the U. S., at Bolton, Mass., with scapolite; at Peru, Maine, with spodumene in albite. According to Bigsby, in a boulder containing tremolite, at York, near Toronto, Canada.

*Lithia* was first discovered in this mineral by Arfvedson. The name *petalite* is from *πέταλον, a leaf*, alluding to the cleavage.

**Ref.**—[1] Ann. Ch. Phys., 3, 264, 1864, and Pogg., **122**, 648, 1864. Cf. Svr., Zs. G. Ges., **22**, 668, 1870. [2] L. c., also Min., **2**, xxxvi, 1874. [3] C. R., **106**, 777, 1888.

HYDROCASTORITE. Idrocastorite *G. Grattarola*, Boll. Com. Geol., 323, 1876. A decomposition product of Elba castorite. Occurs as a white mealy aggregate of fine crystalline needles, surrounding a nucleus of the original mineral. H. = 2. G. = 2·16. Anal.—1, Grattarola, on material not entirely pure. 2, Sansoni, Att. Soc. Tosc., **4**, 320, 1879.

| | $SiO_2$ | $Al_2O_3$ | CaO | MgO | $H_2O$ | | |

| 2. | 58·13 | 19·70 | 4·17 | 0·50 | 15·96 | = | 98·46 |

### 311. MILARITE. *Kenngott*, Jb. Min., 81, 1870. Giufite *Kuschel-Köhler*, ib., 926, 1877.

Hexagonal. Axis $\dot{c} = 0·6620$; $0001 \wedge 10\bar{1}1 = {}^*37° 23\tfrac{2}{3}'$ Rinne[1]. In hexagonal prisms with *c* (0001), *m* $(10\bar{1}0)$, *a* $(11\bar{2}0)$, *p* $(10\bar{1}1)$. Pyramidal angles : $pp' = 55°$ 21′, $pp^{vi} = 105° 13'$.

Cleavage not observed. Fracture conchoidal. Brittle. H. = 5·5–6. G. = 2·55–2·59. Luster vitreous. Colorless to pale green, glassy.

Basal sections show, in polarized light, a division into six radial sectors (biaxial), often with a central core diagonally placed and also divided into six sectors. The central portion is sometimes uniaxial. Hence regarded as pseudohexagonal (analogous to witherite) by Tschermak[2], Des Cloizeaux[3], Mallard[4]. Rinne[1], however, shows that the original position of equilibrium was hexagonal and the anomalous characters are secondary; this is confirmed by Ramsay[5], who finds that increase of temperature makes the biaxial portions become uniaxial.

**Comp.**—$HKCa_2Al_2(Si_2O_5)_6$ or $H_2O.K_2O.4CaO.2Al_2O_3.24SiO_2$ = Silica 72·7, alumina 10·3, lime 11·3, potash 4·8, water 0·9 = 100.

**Anal.**—1, Frenzel, Jb. Min., 797, 1873. 2, Finkener, ib., 62, 1874. 3, Ludwig, Min. Mitth., 347, 1877.

| | | | $SiO_2$ | $Al_2O_3$ | CaO | MgO | $Na_2O$ | $Ka_2O$ | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|---|---|
| 1. | G. = 2·59 | | 71·12 | 8·45 | 11·27 | — | [7·61] | — | 1·55 | = 100 |
| 2. | G. = 2·5 | | 70·04 | 11·62 | 10·05 | 0·20 | 0·65 | 5·74 | 1·69 | = 99·99 |
| 3. | G. = 2·553 | $\frac{2}{3}$ | 71·81 | 10·67 | 11·65 | *tr.* | *tr.* | 4·86 | 1·36 | = 100·35 |

**Pyr., etc.**—B.B. in the closed tube becomes white and gives off water, but only at a high temperature. In the forceps fuses with intumescence to a white blebby glass. In salt of phosphorus slowly soluble to a colorless glass leaving a skeleton of silica. Insoluble in hydrochloric acid.

**Obs.**—Occurs in Val Giuf, Grisons, Switzerland, in a granitic rock with smoky quartz, orthoclase, apatite, titanite, chabazite; the crystals are often coated or penetrated by scales of chlorite. Also reported from the Strim glacier in the Tavetschthal. It was first incorrectly announced as having been found in Val Milar, hence the name first given.

**Ref.**—[1] Jb. Min., 2, 1, 1885; cf. Kenng., *pp'* = 35° 14'; also Tschermak[2], who shows the variation from strict hexagonal symmetry. [2] Min. Mitth., 350, 1877. [3] Jb. Min., 41, 371, 1878. [4] Bull. Soc. Min., 5, 241, 1882. [5] Öfv. Ak. Stockh., **42**, No. 9, 29, 1885.

---

### 312. EUDIDYMITE. *W. C. Brögger*; Nyt Mag., 31, 196, 1887.

Monoclinic. Axes $\grave{a} : \bar{b} : \grave{c} = 1·71075 : 1 : 1·10712$; $\beta = 86° 14\frac{1}{2}' = 001 \wedge 100$ Brögger[1].

$100 \wedge 110 = 59° 38\frac{1}{3}'$, $001 \wedge 101 = 31° 46\frac{2}{3}'$, $001 \wedge 011 = 47° 51'$.

**Forms**[1]: *l* (310, *i*-$\bar{3}$) *x* (10·0·1, – 10-ĭ) *e* (0·10·3, $\frac{10}{3}$-ĭ) *o* (111, – 1) *v* ($\bar{3}$34, $\frac{3}{4}$)
*b* (010, *i*-ĭ) *d* (502, – $\frac{5}{2}$-ĭ) *q* ($\bar{5}$01, 5-ĭ) *u* (335, – $\frac{3}{5}$) *s* (552, – $\frac{5}{2}$) *t* ($\bar{5}$51, 5)
*c* (001, *O*)

Also doubtful 112, $\bar{3}$32.

*ll'''* = 59° 16'
*cl* = *86° 44'
*cd* = 55° 35'
*cq* = 76° 17'

*ee'* = 149° 37'
*cu* = 36° 49'
*co* = *50° 50'
*cs* = 70° 56'

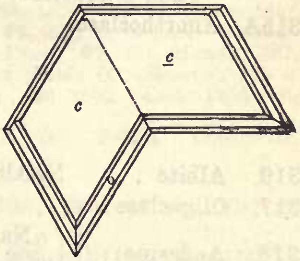
*cv* = 44° 45'
*ct* = 82° 59'
*uu'* = 62° 19'
*oo'* = *84° 2'

*ss'* = 109° 21½'
*vv'* = 74° 51½'
*tt'* = 117° 56'

Twins: tw. pl. (1) *c*, producing tw. lamellæ, also as penetration-twins; also (2) a plane normal to *c* in the zone *co*, contact-twins (f. 2), the axes crossing at angles of nearly 60°. Crystals always twins; habit tabular ‖ *c*. Faces *c*, also the pyramids, often striated ‖ their intersection edges.

1.

2.



Cleavage: *c* perfect; *t* ($\bar{5}$51) less perfect. H. = 6. G. = 2·553. Luster on crystalline faces vitreous, on *c* pearly, also on fracture surfaces in zone *co* silky. Color white. Transparent to translucent.

Optically +. Ax. pl. ‖ *b*. $Bx \wedge \grave{c} = -58° 30'$. Refractive indices:

$\alpha_r = 1·54444$ $\beta_r = 1·54479$ $\gamma_r = 1·54971$ $\therefore$ $2V_r = 30° 44'$
$\alpha_y = 1·54533$ $\beta_y = 1·54568$ $\gamma_y = 1·55085$ $\therefore$ $2V_y = 29° 55'$
$\alpha_{gr} = 1·54763$ $\beta_{gr} = 1·54799$ $\gamma_{gr} = 1·55336$ $\therefore$ $2V_{gr} = 28° 52'$

Also measured axial angles:

$2H_{a.r} = 30° 48'$ $2H_{o.r} = 155° 45'$ $\therefore$ $2V_r = 30° 23\frac{1}{2}'$
$2H_{a.y} = 29° 43'$ $2H_{o.y} = 157° 5'$ $\therefore$ $2V_y = 29° 19'$
$2H_{a.gr} = 28° 54'$ $2H_{o.gr} = 158° 40'$ $\therefore$ $2V_{gr} = 28° 30'$

**Comp.**—$HNaBeSi_3O_8$ or $H_2O.Na_2O.2BeO.6SiO_2$ = Silica 73·4, glucina 10·2, soda 12·7, water 3·7 = 100.

**Anal.**—1, G. Flink, Nyt Mag., l. c., as corrected by A. E. Nd., l. c. 2, A. E. Nordenskiöld, G. För. Förh., **9**, 434, 1887.

| | $SiO_2$ | BeO | $Na_2O$ | $H_2O$ |
|---|---|---|---|---|
| 1. | 72·19 | 11·15 | 12·66 | 3·84 = 99·84 |
| 2. | 73·11 | 10·62 | 12·24 | 3·79 MgO *tr.* = 99·76 |

**Pyr.**—B.B. fuses easily to a colorless glass. Dissolves with difficulty and incompletely in acids. The water goes off completely only at a high temperature.

**Obs.**—Occurs very sparingly in zircon-syenite on the island Ovre-Arö, in the Langesundfiord, with ægirite, elæolite, brevicite, apophyllite, natrolite, etc.; it was formed at the same time with the zeolites with which it is associated.

Named from εὖ, *well*, δίδυμος, *twin*, in allusion to its occurrence in twin crystals.

It is interesting to note that a considerable number of the minerals containing beryllium as an essential constituent (*e.g.* beryl, phenacite) are hexagonal, like the element itself (Brögger & Flink, Zs. Kr., 9, 228, 1884), or approximate to this in angle and method of twinning (*e.g.* eudidymite, chrysoberyl, beryllonite, bertrandite, etc.).

The general characters of the species belonging in the FELDSPAR GROUP are as follows: 1, Crystallization in the monoclinic or triclinic systems, the crystals of the different species resembling each other closely in angle, in general habit, and in methods of twinning. 2, Cleavage in two similar directions inclined at an angle of 90° or nearly 90°. 3, Hardness between 6 and 6·5. 4, Specific Gravity varying between 2·5 and 2·9, and mostly between 2·55 and 2·75. 5, Colors white or pale shades of yellow, red or green, less commonly dark. 6, In composition silicates of aluminium with either potassium, sodium, or calcium, and rarely barium, while magnesium and iron are always absent. Furthermore, besides the several distinct species there are many intermediate compounds having a certain independence of character and yet connected with each other by insensible gradations; all the members of the series showing a close relationship not only in composition but also in crystalline form and optical characters.

The feldspars furnish a striking example how a species, or group of species, may approximate in angle to a system of higher symmetry, while diverging widely from it in actual form. Thus of the commonly occurring planes of orthoclase: *n* (021), *y* ($\bar{2}01$) correspond in angle to cubic planes; *q* ($\bar{2}03$) to an octahedral; *m, b, c, o* (111) to dodecahedral, and *z* (130), *x* ($\bar{1}01$) to trapezohedral. See further 5th Ed., p. 337, where this subject is developed and a relation to the isometric species leucite is shown.

The species of the Feldspar Group are classified, first as regards form, and second with reference to composition. The *monoclinic* species include (see above): ORTHOCLASE, potassium feldspar and SODA-ORTHOCLASE, potassium-sodium feldspar; also HYALOPHANE, barium feldspar.

The *triclinic* species include: MICROCLINE and ANORTHOCLASE, potassium-sodium feldspars; ALBITE, sodium feldspar; ANORTHITE, calcium feldspar.

Also intermediate between albite and anorthite the isomorphous sub-species, sodium-calcium or calcium-sodium feldspars: OLIGOCLASE, ANDESINE, LABRADORITE.

Many planes with abnormal indices have been noted, especially on adularia, also others of doubtful character. Of these "vicinal planes" Websky[8] describes a large number, and others have been added by Becker[4], Koksharov (l. c.), Des Cloizeaux[6], Cathrein[9, 10], Hamberg[19], Zepharovich[13].

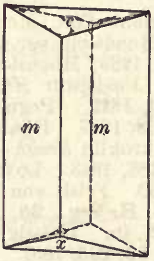
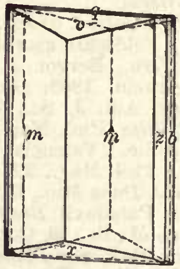
7.



8.



Figs. 1–5. Simple forms. 6, *Loxoclase*, Hammond, N. Y. 7, 8, *Adularia*, Brown.

Twins: tw. pl. (1) *a*, or tw. axis c̍, the common *Carlsbad* twins, either of irregular penetration (f. 11) or contact type; the latter usually with *b* as composition-face, often then (f. 10) with *c* and $\underline{x}$ nearly in a plane, but to be distinguished by luster, etc.; also rarely united by *a*. (2) *n* (021), the *Baveno* twins forming nearly square prisms (f. 13, 14), since $cn = 44° 56\frac{1}{2}'$ and hence $c\underline{c} = 89° 53'$; often repeated as fourlings (f. 15), also in square prisms, elongated ‖ à. (3) *c*, the *Manebach* twins (f. 12), usually contact-twins with *c* as comp.-face. Less common than these, and usually of the penetration and cruciform type, often of Carlsbad twins: (4) *m*; (5) *z* (130); (6) $\bar{1}02$?; (7) *y* $(\bar{2}01)$; (8) 051; (9) *o* (111); (10) 454; (11) 2·5·15. Some of these apparent twins may be simply accidental groupings, analogous to those common with quartz.

Crystals often prismatic ‖ c̍; sometimes orthorhombic in aspect (f. 2, 7) since *c* and *x* are inclined at nearly equal angles to c̍; also elongated ‖ à (f. 9) with *b* and *c* nearly equally developed; also thin tabular ‖ *b*; rarely tabular ‖ *a*, a face not often observed. Faces $c$, $x$ often horizontally striated and united in oscillatory combination, forming flat or rounded summits. Faces $x$ often rough and thus distinguished from $c$ in twins (f. 10). Vicinal forms common, especially with adularia.

Often massive, coarsely cleavable to granular; sometimes lamellar. Also compact crypto-crystalline, and flint-like or jasper-like.

Cleavage: $c$ perfect; $b$ somewhat less so; prismatic $m$ imperfect, but usually more distinct parallel to one prismatic face than to the other. Parting[15] sometimes distinct parallel to $a$ (100), also to a hemi-orthodome $\varDelta$ ($\bar{7}01$, or $\bar{8}01$), inclined a few degrees to the orthopinacoid ($c\varDelta = 73°$ to $74°$); this may produce a satin-like luster or schiller, the latter also often present when the parting is not distinct. This parting and the schiller may be secondary in origin. Fracture conchoidal to uneven. Brittle. H. = 6–6·5. G. = 2·5–2·62. Luster vitreous; on a cleavage-surface ($c$) often pearly. Colorless, white, pale yellow and flesh-red common, gray; rarely green. Streak uncolored.

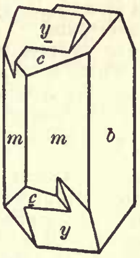
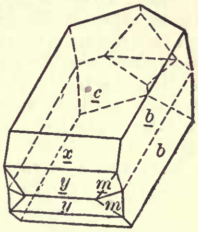
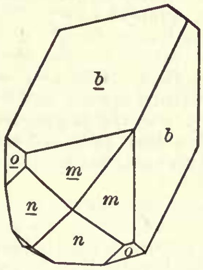
11.



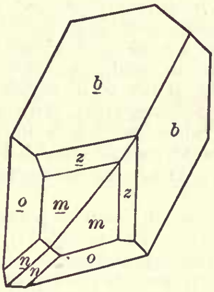
12.



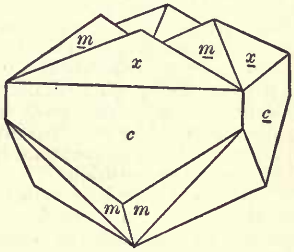
13.



14.



15.



10, 11, Carlsbad twins. 12, Manebach twin, Sbk. 13, 14, Baveno twins, Brown.
15, Do., fourling, Hbg.

Optically negative ($Bx_a = \mathfrak{a}$) in all cases. Ax. pl. usually $\perp b$, sometimes $\parallel b$, also changing from the former to the latter on increase of temperature (see below). For *adularia* (Dx.) $Bx_{a.r} \wedge \grave{c} = -69° 11'$, $Bx_{a.bl} \wedge \grave{c} = -69° 37'$. Hence $Bx_a$ and the extinction-direction (cf. f. 3, p. 326) inclined a few degrees only to $\grave{a}$, or the edge $b/c$; thus $+3°$ to $+7°$ usually, or up to $+10°$ or $+12°$ (in varieties rich in $Na_2O$) according to Rosenbusch. Dispersion $\rho > v$; also horizontal, strongly marked, or inclined, according to position of ax. pl. Axial angles variable. Indices and axial angles at 18° C., Dx.:

*Adularia:*

No. 1 $\alpha_y = 1·5190$ $\beta_y = 1·5237$ $\gamma_y = 1·5260$ $\therefore$ $2V_y = 69° 43'$ $2E_y = 121°$ 6,
Also measured $2E_r = 120° 22'$, $2E_y = 120° 12'$, $2E_{bl} = 118° 37'$

No. 2 $\alpha_y = 1·5181$ $\beta_y = 1·5223$ $\gamma_y = 1·5243$ $\therefore$ $2V_y = 69° 1'$ $2E_y = 119°$ 11,
Measured $2Er_r = 120° 42'$, $2E_y = 129° 46'$, $2E_{bl} = 118° 18'$

*Sanidine*, Wehr, ax. pl. $\perp$ *b* for red rays:

$$\alpha_r = 1{\cdot}5170 \quad \beta_r = 1{\cdot}5239 \quad \gamma_r = 1{\cdot}5240 \quad \therefore \quad 2V_r = 13^\circ\, 34' \quad 2E_r = 20^\circ\, 45$$

Same, ax. pl. $\parallel$ *b* for blue rays:

$$\alpha_{bl} = 1{\cdot}5265 \quad \beta_{bl} = 1{\cdot}5355 \quad \gamma_{bl} = 1{\cdot}5356 \quad \therefore \quad 2V_{bl} = 11^\circ\, 51' \quad 2E_{bl} = 18^\circ\, 14'$$

Increase of temperature diminishes the axial angle when the ax. pl. is $\perp$ *b*, but increases it when $\parallel$ *b*. In the former case the angles for the different colors successively become 0° and the ax. pl. changes to the second position. If the temperature is maintained as high as 600° to 1000° the change becomes permanent. Cf. Dx., Weiss.[16] Pressure produces a like change.

**Comp., Var.**—A silicate of aluminium and potassium, $KAlSi_3O_8$ or $K_2O.Al_2O_3.6SiO_2$ = Silica 64·7, alumina 18·4, potash 16·9 = 100. Sodium is often also present, replacing part of the potassium.

The prominent varieties depend upon crystalline habit and method of occurrence more than upon difference of composition.

1. *Adularia.* The pure or nearly pure potassium silicate. Usually in crystals, like f. 7, 8 in habit; often with vicinal planes, especially on the Baveno twins, which are very common with this variety. G. = 2·565 Tsch. Transparent or nearly so. Often with a pearly opalescent reflection or schiller $\parallel$ *a* or *Δ*; sometimes with a delicate play of colors; some *moonstone* (Hecatolite *Delameth.*, T. T., 2, 201, from *ἑκάτη, the moon*) is here included, but the remainder belongs to albite or other of the triclinic feldspars.

The original adularia (Adular) is from the St. Gothard region in Switzerland. The name is derived from the Adular Mts., which term as used by Strabo embraced the Central High Alps, including the Gothard region and the Adular Mts., etc. In the latter, in the present restricted sense, the adularia is not found (Kenngott). The name is extended also to similar varieties from other points in the Alps and elsewhere. *Valencianite*, from the silver mine of Valencia, Mexico, is adularia.

2. *Sanidine* or *glassy feldspar.* Occurs in crystals, often transparent and glassy, embedded in lava, trachyte, phonolyte, etc. Habit often tabular $\parallel$ *b* (hence named from *σανίς*, a *tablet*, or *board*); also in square prisms (*b*, *c*); Carlsbad twins very common. Most varieties contain sodium as a prominent constituent. Cf. anal. 5–10.

*Rhyacolite. Eisspath* Werner. Occurs in glassy crystals at Monte Somma; named from *ρύαξ*, *stream* (lava stream), and *λίθος*, *stone;* anal. 11.

3. *Ordinary.* In crystals (f. 1–6, and f. 10) Carlsbad and other twins common; also massive or cleavable, varying in color from white to pale yellow, red, or green, translucent; sometimes aventurine. Here belongs the common feldspar of granitoid rocks or granite veins. Usually contains a greater or less percentage of soda (soda-orthoclase, Natronorthoklas *Germ.*, cf. anal. 22, 23). Compact crypto-crystalline orthoclase makes up the mass of much felsite, but to a greater or less degree admixed with quartz; it occurs of various colors, from white and brown to deep red. There are two kinds: (*a*) the *jasper-like*, with a subvitreous luster; and (*b*) the *ceratoid* or *wax-like*, with a waxy luster. Some red kinds look closely like red jasper, but are easily distinguished by the fusibility. *Leelite*, named after J. F. Lee, is a deep flesh-red variety, of waxy luster, from Grythyttan, Sweden. Other felsites contain soda and approximate to albite or oligoclase in composition.

Much of what has been called orthoclase, or common potash feldspar, has proved to belong to the related triclinic species, microcline. Cf. p. 323 on the relations of the two species. Chesterlite and Amazonite or Amazon stone, are microcline; also most aventurine orthoclase.

The following names belong to more or less distinctly characterized varieties of common orthoclase:

*Loxoclase.* Contains sodium in considerable amount (anal. 21). In grayish white or yellowish crystals (f. 6), a little pearly or greasy in luster, feebly shining, often large, lengthened usually in the direction of the clinodiagonal. From Hammond, St. Lawrence Co., N. Y. Named from *λοξός*, *transverse*, and *κλασις*, *fracture*, under the idea that the crystals are peculiar in having cleavage parallel to the orthodiagonal section.

*Paradoxite* Breith. is a flesh-red feldspar from the tin mines near Marienberg. *Cottaite* Breith. is a grayish white feldspar in twins from Carlsbad, Bohemia. *Muldan* is from Mulda near Freiberg. *Pegmatolite* Breith. is common feldspar.

*Erythrite* Thomson. A flesh-red variety from near Kilpatrick.

*Necronite.* A cleavable feldspar, fetid in odor when struck. The original was found by Hayden near the York and Lancaster road, 21 m. from Baltimore, in granular limestone, and was whitish or bluish in color. Named from *νεκρός*, *a corpse.*

*Lazurfeldspar* (Lasurfeldspath *Germ.*). A feldspar having H. = 6, and G. = 2·597, has the cleavage of orthoclase, found near Lake Baikal with lapis lazuli.

*Perthite.* A flesh-red aventurine feldspar, consisting of interlaminated albite and orthoclase. From Perth, Quebec. See further p. 321.

*Murchisonite.* A flesh-red feldspar similar to perthite, with gold-yellow reflections in a direction $\perp$ *b* and inclined 73° 13′ to *c* (Dx.), hence nearly parallel to $\bar{7}01$ or $\bar{8}01$ (see cryptoperthite, p. 321). Stated to have also an unusual cleavage direction besides the two observed. From Dawlish and Exeter, England. Named after its discoverer, Murchison the geologist.

*Weissigite* Jenzsch. In small whitish or reddish white twin crystals, from the cavities of amygdaloid at Weissig near Dresden; G. = 2·538–2·546. I. Lea has named (Proc. Ac. Philad., May, 1866) a greenish orthoclase from Lenni, Delaware Co., Pa., "almost without cleavage," *lennilite;* other specimens of the same locality, pearly and distinctly cleavable, *delawarite;* and a dull bluish-green subtransparent kind, of an aventurine character, from Blue Hill, 2 m. N. of Media, Pa., *cassinite* (see p. 322).

**Pyr., etc.**—B.B. fuses at 5; varieties containing much soda are more fusible. Loxoclase fuses at 4. Not acted upon by acids.

**Obs.**—Orthoclase in its several varieties belongs especially to the crystalline rocks, occurring as an essential constituent of granite, gneiss, syenite, also porphyry, further (var., *sanidine*) trachyte, phonolyte, etc. In the massive granitoid rocks it is seldom in distinct, well formed, separable crystals, except in veins and cavities; such crystals are more common, however, in volcanic rocks like trachyte.

*Adularia* occurs in the crystalline rocks of the central and eastern Alps, associated with smoky quartz and albite, also titanite, apatite, etc.; the crystals are often coated with chlorite. Thus in the St. Gothard region, especially on Mt. Fibia; also the Maderanerthal in Uri, Kreuzlithal and Tavetschthal, Lukmanier in Grisons, Guttanen in the Bernese Oberland (cf. Kenng., Min. Schweiz, pp. 45–75). Further in the Eastern Alps, as at Schwarzenstein in the Zillerthal. Also in crevices in trachyte at Felsöbánya. On Elba. Fine crystals of orthoclase, often twins, are obtained from Baveno, Lago Maggiore; the Fleimsthal, a red variety; Valfloriana; Bodenmais, Carlsbad and Elbogen in Bohemia; Striegau, Hirschberg, and Lomnitz in Silesia. Also Ekaterinburg in the Ural; Albaschka near Mursinka; Arendal in Norway, and near Shaitansk in the Ural; Land's End and St. Agnes in Cornwall; at Rubislaw in Aberdeenshire, Scotland. The Mourne Mts., Ireland, with beryl and topaz. Tamagama Yama, Japan, with topaz and smoky quartz. *Moonstone* is brought from Ceylon.

Typical *sanidine* is prominent in the trachyte of the Drachenfels on the Rhine; at the Laacher See. *Rhyacolite* occurs in blocks on Mt. Somma and in the Albani Mts.; in Latium near Rome; in the lavas of Ischia; near Naples.

In the U. States, orthoclase in crystals occurs in *Maine*, on the island Mt. Desert, fine green;

at the tourmaline locality, Paris; at Buckfield. In *N. Hamp.*, at the Acworth beryl locality. In *Mass.*, at South Royalston and Barre, often large crystals; at Three Rivers, in Palmer. In *Conn.*, at the gneiss quarries of Haddam and the feldspar quarries of Middletown, crystals a foot long, and 6 or 8 in. thick; near Bradleysville, in the western part of Litchfield, crystals 2–3 in. long, abundant; at Willimantic. In *N. York*, in St. Lawrence Co., at Rossie, 2 m. N. of Oxbow, the crystals are white or bluish white, and sometimes an inch across; also 8 m. from Potsdam, on the road to Pierrepont, where crystals a foot through are said to have been found; and near DeLong's mills in the town of Hammond, with apatite and zircon, where the *loxoclase* is obtained; in Lewis Co., orthoclase occurs both crystallized and massive in white limestone near Natural Bridge, with scapolite and titanite; in Orange Co., crystals near West Point; more abundant and interesting forms are found at Rocky Hill, in Warwick, with tourmaline and zircon; and at Amity and Edenville; in Saratoga Co., at the Greenfield chrysoberyl locality, white translucent crystals, usually coated with silvery mica. In *Penn.*, in crystals at Leiperville, Mineral Hill, Delaware Co.; sunstone in Kennett Township; French Creek, a peculiar variety with divergent columnar structure of a reddish color (anal. 20). In *N. Car.*, at Washington Mine, Davidson Co., in white and yellowish crystals. At the Superior mine, Ontonagon, Lake Superior, in small reddish crystals, as a secondary product, in cavities in amygdaloid with epidote. In *Colorado*, at the summit of Mt. Antero, Chaffee Co., in fine crystals, often Carlsbad and Baveno twins, with beryl, phenacite, bertrandite, etc.; at Gunnison; Black Hawk; Kokoma, Summit Co., also at other points. Also similarly in Nevada and California.

Orthoclase as a secondary mineral in cavities in a basaltic rock, with calcite and phillipsite at Eulenberg, Bohemia, was described by Zepharovich, Ber. Ak. Wien, **91** (1), 158, 1885. Gränzer has further studied the same occurrence, and finds the mineral to deviate somewhat (but probably not essentially) from normal orthoclase; thus the composition $(H,K)AlSi_3O_8$ is assigned to it, with H : K = 1 : 8, Min. Mitth., **11**, 277, 1890.

**Alt.**—Feldspar may be altered through infiltrating waters carrying more or less carbon dioxide in solution (Forchhammer, Fournet, Bischof); also through the action of waters rendered acid by the decomposition of sulphides (Mitscherlich); also by ordinary waters holding traces of alkaline and other ingredients in solution (Bischof).

The presence of iron sulphide, or a mineral containing iron protoxide, as some mica, garnet, etc., is often the first occasion of the change. The decomposition of the mineral with the attendant oxidation of the iron distributes ferruginous waters through the rock (or ferrous sulphate from the altered sulphide), and thus, by a decomposing action, prepares the way for other agencies.

When the infiltrating waters contain traces of carbon dioxide, the feldspar acted on first loses its lime, if a lime feldspar, by a combination of the lime with this acid; next, its alkalies are carried off as carbonates, if the supply of carbonic acid continues, or otherwise as silicates in solution. The change thus going on ends in forming *kaolin* or some other aluminous silicate. The carbonate of soda or potash, or the silicate of these bases, set free, may go to the formation of other minerals—the production of pseudomorphic or metamorphic changes—and the supplying fresh and marine waters with their saline ingredients. When the change is not carried on to the exclusion of the protoxide bases, certain zeolites may result, especially, as Bischof states, when labradorite is the feldspar undergoing alteration, which species he describes as giving origin to the species mesolite. Massive nephelite or elæolite is a still more common source of zeolites. When the waters contain traces of a magnesian salt—a bicarbonate or silicate—the magnesia may replace the lime or soda, and so lead to a steatitic change, or to a talc when the alumina is excluded; and when augite or hornblende is present, it may give origin to chlorite. The action of sulphurous acid from volcanic fumaroles produces often a complete destruction of the feldspar and other minerals present, giving rise to deposits or incrustations of silica, in some of its various forms, and also halloysite, kaolin, etc.

Steatite, talc, chlorite, kaolin, lithomarge, mica, laumontite, occur as pseudomorphs after orthoclase or albite; and cassiterite and calcite often replace these feldspars by some process of solution and substitution. Labradorite more rarely forms kaolin. The triclinic lime-soda feldspars are sometimes altered to saussurite (wh. see); also to scapolite, cf. Judd, Min. Mag., **8**, 186, 1889.

On pseudomorphs of orthoclase after leucite, see E. Scacchi, Rend. Acc. Napoli, Dec. 1884. Sauer, Zs. G. Ges., **37**, 456, 1885.

**Artif.**—Artificial feldspar has been observed in crystals in furnace scoria at Mansfeld, Sangerhausen, near Laimbach and near Stolberg.

Obtained by Hautefeuille in distinct crystals with tridymite by heating at a temperature of 900° to 1000° a mixture of tungstic acid with an alkaline silico-aluminate of potash; also with quartz at a lower temperature after the addition of an alkaline fluoride, C. R., **85**, 952, 1877, **90**, 830, 1880. Again by Friedel and Sarasin in the wet way by the reaction of the silicates of alumina and potash and water under pressure, Bull. Soc. Min., **2**, 158, 1879, **4**, 171, 1881. Cf. also Fouqué and Lévy, C. R., **87**, 700, 830, 1878, and Synth. Min., p. 132, 1882.

**Ref.**—[1] Min. Russl., **5**, 115, 1866; cf. measurements by Rath on sanidine and adularia, Pogg., **135**, 454, 1868, and later Strüver on sanidine, Zs. Kr., **1**, 243, 1877. A comparison of results is given by Kk., Min. Russl., **5**, 329, also **9**, 252, 1886.

J. Sc., **27**, 94, 1884. See further Iddings under anorthoclase (p. 324) and Brögger under cryptoperthite, below.

[16] *Refractive indices* and optical phenomena: Heusser, Pogg., **91**, 514, 1854; Dx., Min., **1**, 332, 1862, N. R., 152, 1867, also references under microcline; Ch. E. Weiss, Beitr. z. Kenntniss d. Feldspathbildung, Haarlem, 1866. *Thermal expansion*, Beckenkamp, Zs. Kr., **5**, 452, 1881. *Pyroelectricity*, Hankel, Wied., **1**, 280, 1877.

Perthite *Thomson*, Phil. Mag., **22**, 189, 1843. A flesh-red aventurine feldspar from Perth, Quebec, Canada, called a soda-orthoclase, but shown by Gerhard (Zs. G. Ges., **14**, 151, 1862) to consist of interlaminated orthoclase and albite. Many similar occurrences have since been noted, as also those in which microcline and albite are similarly interlaminated, then called *microcline-perthite*, or microcline-albite-perthite; this is true in part of the original perthite. When the structure is discernible only with the help of the microscope it is called microperthite. See Mann, Jb. Min., 389, 1879; also Kloos, ib., **2**, 89, 1884; Woitschach, Zs. Kr., **7**, 82, 1883.

Brögger has investigated not only the microperthites of Norway (Orthoklasmikroperthit, Mikroklinmikroperthit) but also other feldspars characterized by a marked schiller; he assumes the existence of an extremely fine interlamination of albite and orthoclase ∥ $\bar{8}$01. not discernible by the microscope (cryptoperthite, Kryptoperthit) and connected with secondary planes of parting ∥ 100 or ∥ $\bar{8}$01, which is probably to be explained as due to incipient alteration. See further Zs. Kr., **16**, 524, 1890.

Krablite *Forchhammer*, 1842. Baulite. Kraflit *Flink*, Öfv. Ak. Stockh, Bihang., **12** (2), No. 2, 64, 1886. Described as a kind of feldspar, very high in silica, but shown by Brögger and Flink to be a liparyte, containing well formed crystals of orthoclase enclosing a plagioclase kernel, also quartz, etc. Flink calculates for the orthoclase: $\grave{a} : \bar{b} : \grave{c} = 0\cdot64374 . 1 : 0\cdot55079$; $\beta = 63° 52'$. From Krabla (Krafla), Iceland. See 5th Ed., pp. 359, 360.

## 314. HYALOPHANE. *S. von Waltershausen*, Pogg. Ann., **94**, 134, 1855; **100**, 547, 1857.

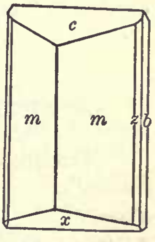
Monoclinic. Axes $\grave{a} : \overset{1}{\bar{b}} : \grave{c} = 0\cdot6584 : 1 : 0\cdot5512$ ; $\beta = 64° 25\frac{1}{4}' = 001 \wedge 100$ Obermayer[1].

$100 \wedge 110 = 30° 42\frac{1}{4}'$, $001 \wedge \bar{1}01 = 49° 47'$, $001 \wedge 011 = 26° 26\frac{1}{6}'$.

**Forms**[2]: *a* (100, $i$-$\bar{\imath}$)[4], *b* (010, $i$-$\grave{\imath}$), *c* (001, *O*); *m* (110, *I*), *z* (130, $i$-$\grave{3}$)[1]; *x* ($\bar{1}$01, 1-$\bar{\imath}$), $\omega$ ($\bar{3}$02, $\frac{3}{2}$-$\bar{\imath}$)[4]; *p* ($\bar{1}$11, 1)[3,4]; $\psi$ ($\bar{1}$41, 4-$\grave{4}$)[4].

Also probable, Rinne[4]: $\delta$ ($\bar{1}$03), $\phi$ ($\bar{1}$02), $\lambda$ ($\bar{6}$05), $\iota$ (113, $-\frac{1}{3}$), $\rho$ ($\bar{1}$13, $\frac{1}{3}$), $\alpha$ ($\bar{1}$12), $\epsilon$ ($\bar{7}$75, $\frac{7}{5}$); and Kenng.[3]: *q* ($\bar{2}$03), *y* ($\bar{2}$01).

$mm''' = {}^*61° 24\frac{1}{2}'$ $c\omega = 67° 59\frac{1}{2}'$ $c\psi = 73° 17\frac{1}{2}'$ $\psi\psi' = 127° 7'$
$zz' = 58° 37'$ $cp = 54° 46'$ $a'p = 68° 31'$ $m'x = {}^*69° 21\frac{1}{2}'$
$cx = 49° 47'$ $cm' = {}^*111° 47\frac{1}{2}'$ $pp' = 53° 23'$



Binnenthal, Obermayer.

In crystals, like adularia in habit. Also massive.

Cleavage: *c* perfect; *b* somewhat less so. Fracture conchoidal. Brittle. H. = 6–6·5. G. = 2·805. Luster vitreous. Colorless to white; also flesh-red. Transparent to translucent.

Optically −. Ax. pl. and $Bx_o \perp b$. $Bx_a \wedge \grave{c} = -69° 25'$, i.e. extinction on *b* inclined about + 5° or 6° to edge *b/c*. Dispersion horizontal, distinct. Axial angles, Rinne:

$2H_{a.r} = 83° 50'$ $2H_{o.r} = 107° 17'$ $\therefore 2V_r = 79° 21'$ $\beta_r = 1·5388$ Li
$2H_{a.y} = 83° 25'$ $2H_{o.y} = 107° 30'$ $\therefore 2V_y = 79° 3'$ $\beta_y = 1·5392$ Na
$2H_{a.gr} = 83° 2'$ $2H_{o.gr} = 107° 52'$ $\therefore 2V_{gr} = 78° 42'$ $\beta_{gr} = 1·5416$ Tl

**Comp.**—A silicate of aluminium, barium, and potassium, $(K_2,Ba)Al_2Si_4O_{12}$ or $K_2O.BaO.2Al_2O_3.8SiO_2$. This is usually written $BaAl_2Si_2O_8.2KAlSi_3O_8$, or a barium silicate analogous to anorthite with orthoclase. This requires: Silica 51·6, alumina 21·9, baryta 16·4, potash 10·1 = 100.

**Pyr., etc.**—B.B. fuses with difficulty to a blebby glass. Unacted upon by acids.

**Obs.**—Occurs in a granular dolomite, along with white barite, greenish tourmaline, mica, realgar, dufrenoysite, and sphalerite, near Imfeld, in the Binnenthal in the Valais, in crystals 2 or 3 lines long, and rarely larger; also at the manganese mine of Jakobsberg in Wermland, Sweden, in limestone with a manganiferous epidote, in part looking much like common flesh-red orthoclase, also in bluish green varieties. A massive feldspar accompanies it, containing only 3·50 p. c. BaO, Igelström.

**Ref.**—[1] Zs. Kr., **7**, 64, 1882. [2] Cf. Waltershausen, l. c. [3] Min. Schweiz, p. 86, 1866. [4] Rinne, Jb. Min., **1**, 207, 1884.

The following are analyses of other BARIUM FELDSPARS, more or less fully investigated: 1, Knop, Jb. Min., 687, 1865; a monoclinic feldspar in the nephelite-doleryte of Meiches in the Vogelsberg. 2, Pisani, Bull. Soc. Min., **1**, 84, 1878; a feldspar of unknown source; optically it lies between oligoclase and albite, cleavage angle *bc* = 86° 37', Dx. 3, Genth, Proc. Ac. Philad., p. 110, 1866, Rep. Min., Penn., 224, 1876. 4, Sperry, Am. J. Sc., **36**, 326, 1888; cassinite of Lea from Blue Hill, Delaware Co., Penn.; shown by Penfield to be a monoclinic feldspar (extinction on *b* = + 6°) with albite running through it in thin tapering plates parallel to the orthopinacoid. The analysis corresponds to 35 p. c. albite, 51 p. c. orthoclase, and 13 p. c. of $BaAl_2Si_4O_{12}$. 5, 6, Igelström, G. För. Förh., **10**, 416, 1888; a cleavable feldspar from the Sjö mine, Grythyttan, Örebro, Sweden.

Mitscherlich also mentions finding 0·45 p. c. BaO in adularia, and small amounts (to 2·23) in other feldspars, J. pr. Ch., **81**, 113, 1860; cf. anals. 8, 12, 13, 14, under orthoclase.

## β. *Triclinic Section.*

**315. MICROCLINE.** Mikroklin *Breith.* Schweigg. J., **60**, 324, 1830. *Des Cloizeaux*, Ann. Ch. Phys., **9**, 433, 1876.

Triclinic. Near orthoclase in angles and habit, but the angle *bc* = about 89° 30'.

**Forms**[1]:
*a* (100, *i*-$\bar{i}$, k)
*b* (010, *i*-$\breve{i}$, M)
*c* (001, *O*, P)
*m* (110, *I'*, l)
*M* (1$\bar{1}$0, '*I*, T)
*f* (130, *i*-$\breve{3}$')
*z* (1$\bar{3}$0, '*i*-$\breve{3}$)
*x* ($\bar{1}$01, ,1-$\bar{i}$,)
*ψ* ($\overline{10}$·0·9, ,$\frac{10}{9}$-$\bar{i}$,)
*y* ($\bar{2}$01, ,2-$\bar{i}$,)
*h* ($\bar{3}$01, ,3-$\bar{i}$,)
*p* ($\bar{1}$11, ,1)
*σ* ($\bar{4}$43, ,$\frac{4}{3}$)
*g* ($\bar{2}$21, ,2)
*o* ($\bar{1}\bar{1}$1, 1,)

For amazonite, Dx. (l. c.) gives, *bc* = 89° 44', *b'M* = 60° 58', *cM* = 68° 22'. For the white microcline from Leverett, Mass., *b'M* = 60° 49', *cm* = 67° 43', *cM* = 68° 43', *mM* = 61° 29'.

Klockmann[1] gives $bc = 89° 53'$, $cx = 50° 45'$, $cy = 80° 33'$. Also Schuster (N.-Z. Min., 690, 1885), $bc = 89° 25'$ to $89° 30'$; Sauer and Ussing[2], $bc = 89° 30'$, $cM = 67° 32'$, $b'M = 61°$.

Twins: like orthoclase, according to the Carlsbad, Baveno and Manebach laws. Also polysynthetic twinning according to the albite and pericline laws (p. 326) rarely absent; fine striations due to the former often observable on the basal face; the two methods together giving a double series of fine ~~lamellæ~~ nearly at right angles to each other, hence the peculiar and very characteristic grating-structure of a basal section viewed in polarized light. This structure may be in part secondary[3]. Crystals usually like ordinary orthoclase in habit. Simple crystals without twinning very rare. Also massive cleavable to granular compact.

Cleavage: *c* perfect; *b* somewhat less so; *M* sometimes distinct; *m* also sometimes distinct, but less easy. Fracture uneven. Brittle. H. = 6–6·5. G. = 2·54–2·57. Luster vitreous, on *c* sometimes pearly. Color white to pale cream-yellow, also red, green. Transparent to translucent.

Optically –. Ax. pl. nearly perpendicular (82°–83°) to *b*. $Bx_o$ inclined 15° 26' to a normal to *b*. Dispersion $\rho < v$ about $Bx_o$. Extinction-angle on *c* + 15° 30', on *b* + 5° to 6° (cf. f. 3, p. 326). Axial angles, Dx.:

$$2H_{a.r} = 88° \text{ to } 89° \qquad 2H_{o.r} = 101\tfrac{1}{2}° \text{ to } 104°$$

For the simple crystals from the pegmatyte of Gasern, Sauer and Ussing give: $bc = 89° 30'$; also extinction-angle (Na) on $c + 15° 30'$, on $b + 5° 15'$; also for a section ⊥ cleavages *c*, *b*, extinction-angle with the basal cleavage lines – 13° 48'. Axial angles, etc.:

$$2H_{a.y} = 87° 30' \qquad 2H_{o.y} = 101° 7' \qquad \gamma - \beta = 0·0032 \qquad \beta - \alpha = 0·0040$$

$$\therefore \; 2V_y = 83° 41' \qquad \alpha_y = 1·5224 \qquad \beta_y = 1·5264 \qquad \gamma_y = 1·5296$$

Also to fix the position of the planes of the axes of elasticity:

$$\mathfrak{bc} \wedge 001 = 83° 31' \qquad \mathfrak{ac} \wedge 001 = 12° 8' \qquad \mathfrak{ab} \wedge 001 = 79° 48'$$

$$\mathfrak{bc} \wedge 010 = 106° 1' \qquad \mathfrak{ac} \wedge 010 = 97° 34' \qquad \mathfrak{ab} \wedge 010 = 17° 48'$$

The essential identity of orthoclase and microcline has been urged by Mallard[4] and Michel-Lévy[4] on the ground that the properties of the former would belong to an aggregate of submicroscopic twinning lamellæ of the latter, according to the albite and pericline laws.

**Comp., Var.**—Like orthoclase, $KAlSi_3O_8$ or $K_2O.Al_2O_3.6SiO_2$ = Silica 64·7, alumina 18·4, potash 16·9 = 100. Sodium is usually present in small amount.

**Var.**—1. *Ordinary.* In crystals and cleavable masses chiefly in granitic veins, in external aspect not often to be distinguished from orthoclase. Much so-called aventurine feldspar belongs here, and this variety often encloses lamellæ of albite, as is true to a greater or less extent of most forms.

2. *Amazonstone* or *amazonite.* Bright verdigris-green. Often coated with albite crystals in parallel position.

3. *Chesterlite.* In white crystals, smooth, but feebly lustrous, implanted on dolomite in Chester Co., Penn. It contains but little soda.

**Obs.**—Much of the potash feldspar formerly called orthoclase belongs here; in general only an optical examination serves to establish the difference. It hence occurs under the same conditions as common orthoclase. Some localities are mentioned with the list of analyses; that from Magnet Cove, Arkansas, is nearly pure microcline. The beautiful amazonstone from the Ural, also in fine groups of large crystals of deep color in the granite of Pike's Peak, Colorado, is microcline. *Chesterlite* from Poorhouse quarry, Chester Co., Penn., and the aventurine feldspar of Mineral Hill, Penn., belong here.

Microcline, pseudomorph after spodumene (anal. 18), has been described by Brush and Dana from Branchville, where the species also occurs in very large cleavage masses and crystallized in a pegmatyte vein. Simple crystals occur in pegmatyte of the Gaserntbal near Meissen, Saxony.

The name *mikroklin* was given by Breithaupt to a feldspar occurring chiefly in cleavable masses in the zircon-syenite of Fredriksvärn, also Laurvik and Brevik, Norway. Breithaupt made the angle between the two cleavage planes 90° 22′–90° 23′, instead of 90°; and hence derived the name, from *μικρός*, *little*, and *κλινειν*, *to incline.* Breithaupt referred to microcline the feldspar of Arendal, which afforded him the same angle, also feldspars from a number of other localities. The species, however, was first established by Des Cloizeaux. He shows moreover that the Fredriksvärn feldspar is true orthoclase (cf. remarks by Bgr., cryptoperthite, p. 321).

**315 A. Anorthoclase.** Anorthoklas *Rosenbusch*, Mikr. Phys., 550, 1885. Anorthose *Fr.* Natronorthoklas pt. Natronmikroklin *Förstner*. Mikroklinalbit. Mikroklas *F. J. Wiik*.

A triclinic feldspar with a cleavage-angle, *bc*, varying but little from 90°. Form like that of the ordinary feldspars. Twinning in accordance with the Carlsbad, Baveno, and Manebach laws; also polysynthetic according to the albite and pericline laws; but in many cases the twinning laminæ very narrow and hence not distinct. Rhombic section inclined on *b*, 4° to 6° to edge *b*/*c*. G. = 2·57–2·60. Cleavage, hardness, luster, and color as with other members of the group.

Optically −. Extinction-angle on *c*, + 5° 45′ to + 2°; on *b*, 6° to 9°·8. $Bx_a$ nearly ⊥ *y*. Dispersion $\rho > v$; horizontal distinct. Axial angles (Förstner).

$2E_y = 71° 40′$ Khagiar 88° 27′ Rakhall $\beta_y = 1·5040$ to $1·5810$.

Axial angle variable with temperature, becoming in part monoclinic in optical symmetry between 86° and 264° C., but again triclinic on cooling; this is true of those containing little calcium.

**Comp.**—Chiefly a soda-potash feldspar, $NaAlSi_3O_8$ and $KAlSi_3O_8$, the sodium silicate usually in larger proportion (2 : 1, 3 : 1, etc.), calcium ($CaAl_2Si_2O_8$) present in relatively very small amount.

**Obs.**—These triclinic soda-potash feldspars are chiefly known from the andesytic lavas of Pantelleria. Most of these feldspars come from a rock, called by Förstner pantellerite, which is characterized by the presence of cossyrite; a similar feldspar (anal. 11) resembling sanidine occurs in the basalt of the Hohe Hagen near Göttingen. Also from the augite-syenite of southern Norway and from the "Rhomben-porphyr" near Christiania. The feldspar of Kilima-njaro investigated by Hyland belongs here; probably also other feldspars from Teneriffe; Fréjus in Esterel. An abnormal feldspar from Quatro Ribeiras is mentioned under albite. A feldspar in crystals of unusual habit, tabular ‖ *c*, and twinned according to the Manebach and less often Baveno laws occurs in the lithophyses of the rhyolyte of Obsidian Cliff, Yellowstone Park. It shows the blue opalescence in a direction parallel with a steep orthodome (cf. p. 317).

**Ref.**—Förstner, Zs Kr., **8**, 125, 1883, and on the effect of heat upon the optical character, Zs. Kr., **9**, 333, 1884; also earlier Zs. Kr., **1**, 547, 1877, in which the feldspars examined were all referred to orthoclase. See also Klein, Nachr. Ges. Gött., No. 14, 1878, Jb. Min., 518, 1879, who proves the triclinic character of the Pantelleria feldspar. On the feldspars from the "Rhomben-porphyr" of the Christiania region, as of Tyveholmen (2·5 p. c. $K_2O$) and elsewhere, see Mügge, Jb. Min., **2**, 107, 1881, Bgr., die Silur. Etagen, etc., im Kristiania-Gebiete, etc., pp. 252–307, 1882.

### Albite-Anorthite Series.*

Between the isomorphous species

| | | |
|---|---|---|
| ALBITE | $NaAlSi_3O_8$ | Ab |
| ANORTHITE | $CaAl_2Si_2O_8$ | An |

there are a number of intermediate subspecies, regarded as isomorphous mixtures of these molecules, and defined according to the ratio in which they enter; their composition is expressed in general by the formula $Ab_nAn_m$. They are:

| | | | |
|---|---|---|---|
| OLIGOCLASE | $Ab_6An_1$ | to | $Ab_3An_1$ |
| ANDESINE | $Ab_3An_1$ | to | $Ab_1An_1$ |
| LABRADORITE | $Ab_1An_1$ | to | $Ab_1An_3$ |
| and Bytownite | $Ab_1An_3$ | to | $Ab_1An_6$ |

From albite through the successive intermediate compounds to anorthite with the progressive change in composition (and specific gravity), there is also a corresponding change in crystallographic form, and as developed by Schuster in certain fundamental optical properties.

The relations of the triclinic feldspars, albite, anorthite, and the intermediate compounds in which both sodium and calcium enter, have been discussed by many writers, and various authors, as von Waltershausen, Rammelsberg, Scheerer, and later Delesse and Hunt have made important contributions to the subject. The establishment of the view now accepted, however, is chiefly due to Tschermak[1].

*Crystalline form.* The axial ratios and angles given on p. 314 show that these triclinic feldspars approach orthoclase closely in form, the most obvious difference being in the cleavage-angle *bc*, which is 90° in orthoclase, 86° 24′ in albite, and 85°

---

* The triclinic feldspars of this series, in which the two cleavages *b* and *c* are oblique to each other, are often called in general *plagioclase* (from *πλάγιος, oblique*), a name first introduced by Breithaupt, Min., **3**, 492, 1847.

50′ in anorthite. The transition in form from albite to anorthite is distinctly shown in the change in this angle, *bc*. Thus

| | *bc* | |
|---|---|---|
| Albite | 86° 24′ | Rose |
| Oligoclase (sunstone) | 86° 8′ | Mgc. |
| Andesine | 86° 14′ | Rath |
| Labradorite | 86° 4′ | Tsch. |
| Anorthite | 85° 50′ | Mgc. |

A series of similar measurements is given by Wiik, Zs. Kr., 11, 312, 1885.

There is also a change in the axial angle $\gamma$, which is 88° in albite, about 90° in oligoclase and andesine, and 91° in anorthite. This transition appears still more strikingly in the position of the "rhombic section," by which the twins according to the pericline law are united as explained below.

*Twinning.* The plagioclase feldspars are often twinned in accordance with the Carlsbad, Baveno, and Manebach laws common with orthoclase (p. 316). Twinning is also almost universal according to the *albite law*—twinning plane the brachypinacoid; this is usually polysynthetic, i.e. repeated in the form of thin lamellæ, giving rise to fine striations on the basal cleavage surface. Twinning is also common according to the *pericline law*—twinning axis the macrodiagonal axis $\bar{b}$; when polysynthetic this gives another series of fine striations seen on the brachypinacoid.

The composition-face in this pericline twinning is a plane passing through the crystal in such a direction that its intersections with the prismatic faces and the brachypinacoid make equal plane angles with each other. The position of this rhombic section ("rhombische Schnitt") and the consequent direction of the striations on the brachypinacoid change rapidly with a small change in the angle $\gamma$. In general it may be said to be approximately parallel to the base, but in albite it is inclined backward (+, f. 1, cf. also f. 3) and in anorthite to the front (−, f. 2); for the intermediate species its position varies progressively with the composition (Rath, Wiik, et al.). Thus for the angle between the trace of this plane on the brachypinacoid and the edge *b*/*c*, we have

| | | |
|---|---|---|
| Albite | Ab | + 22° to + 20° |
| Oligoclase-Albite | $Ab_{12}An_1$<br>$Ab_6An_1$ | + 20° to + 10° |
| Oligoclase | $Ab_6An_1$<br>$Ab_3An_1$ | + 9° to + 3½° |
| Andesine | $Ab_3An_2$<br>$Ab_4An_3$<br>$Ab_1An_1$ | + 1°<br>0°<br>− 1° to − 2° |
| Labradorite<br>Bytownite | $Ab_3An_4$<br>$Ab_1An_3$<br>$Ab_1An_6$ | − 9° to − 10° |
| Anorthite | An | − 15° to − 17° |

For special observations see under the individual species beyond.

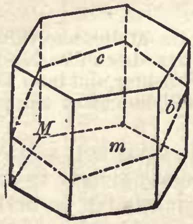
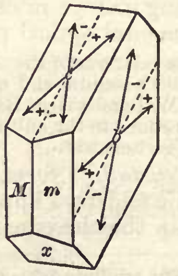
2.



3.

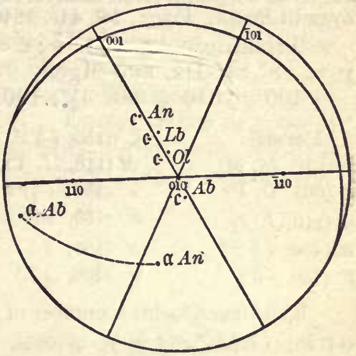


1, Rhombic section in albite. 2, Same in anorthite; 1, 2, after Rath. 3, Typical form showing directions of light-extinction on *c* and *b*.

*Optical characters.* There is also a progressive change in the position of the axes of light-elasticity and the optic axial plane in passing from albite to anorthite, as has been shown by Schuster. This is most simply exhibited by the position of the planes of light-vibration, as observed in sections parallel to the two cleavages, basal *c* and clinopinacoidal *b*, in other words the extinction-angle formed on each face with the edge *b*/*c* (cf. f. 3).

The approximate position of the axes of elasticity for the different feldspars is shown in figure 4 (from Schuster). The axis of least elasticity ($\mathfrak{c}$) does not vary very much from the zone *bc*, but the axis of greatest elasticity ($\mathfrak{a}$) varies widely, and hence the axial plane has an entirely different position in albite from what it has in anorthite. Furthermore albite is optically positive, that is $\mathfrak{c} = \mathrm{Bx}$, while anorthite is negative or $\mathfrak{a} = \mathrm{Bx}$; for certain andesines the axial angle is sensibly 90°.

4.



The following table gives the percentage composition of the various molecular compounds of albite and anorthite, with the calculated specific gravity (Tschermak), and also certain of the optical characters connected with them by the researches of Schuster and Mallard. These latter values are calculated by Schuster from an equation deduced by Mallard, in which certain observed values are assumed as fundamental. Observed angles for many cases are given in the pages which follow.

| | Ratio of Albite to Anorthite $Ab_nAn_m$ | | Percentage Composition | | | | Extinction-angle with edge *c*/*b* | |
|---|---|---|---|---|---|---|---|---|
| | *n* : *m* | G. | $SiO_2$ | $Al_2O_3$ | CaO | $Na_2O$ | on *c* | on *b* |
| Albite | 1 : 0 | 2·624 | 68·7 | 19·5 | 0 | 11·8 | + 4° 30′ | 19° |
| Oligoclase-albite | 12 : 1 | 2·635 | 66·6 | 20·9 | 1·6 | 10·9 | + 3° 38′ to 2° 45′ | + 15° 35′ to 11° 59′ |

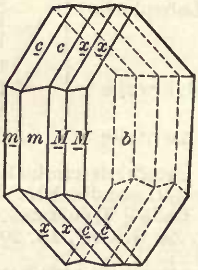

Figs. 1, 2, Schneeberg, Passeir, Rumpf. 3, Pfitsch, Schrauf. 4, Zillerthal, Id. 5, Middletown. 6, Carlsbad twin; 7, Albite and Carlsbad twins combined, Schrauf.

Twins[6]: similar to the (1) Carlsbad, (2) Baveno and (3) Manebach twins of orthoclase (p. 316); (4) tw. pl. *b*, *albite law* (p. 326), usually contact-twins, and polysynthetic, consisting of thin lamellæ and with consequent fine striations on *c*; this twinning is rarely absent in embedded masses and may be sometimes of secondary origin. (5) tw. axis $\bar{b}$, *pericline law*, in contact-twins whose composition-face is the so-called rhombic section (cf. f. 1 p. 326); also often polysynthetic and then showing fine striations which on *b* are inclined backward + 22° to the edge *b/c*. (6) Tw. axis $\breve{a}$, not common. (7) Tw. axis a line in 010 normal to $\dot{c}$.

Crystals often tabular ∥ *b*; also elongated ∥ axis $\bar{b}$, as in the variety pericline. Also massive, either lamellar or granular; the laminæ often curved, sometimes divergent; granular varieties occasionally quite fine to impalpable.

Cleavage: *c* perfect; *b* somewhat less so; *m* imperfect. Fracture uneven to conchoidal. Brittle. H. = 6–6·5. G. = 2·62–2·65. Luster vitreous; on a cleavage surface often pearly. Color white; also occasionally bluish, gray, reddish, greenish, and green; sometimes having a bluish opalescence or play of colors on *c*. Streak uncolored. Transparent to subtranslucent.

An abnormal albite from Quatre Ribeiras, on Terceira, Azores (anal. 24), has been investigated by Fouqué. Its extinction-angles on *c* and *b* are 1° 30′ and 9° to 9° 30′ respectively; it is optically — with $Bx_a$ nearly ⊥ *y* and $Bx_o$ nearly ⊥ *b*.

**Comp.**—A silicate of aluminium and sodium, $NaAlSi_3O_8$ or $Na_2O.Al_2O_3.6SiO_2$ = Silica 68·7, alumina 19·5, soda 11·8 = 100. Calcium is usually present in small amount, as anorthite ($CaAl_2Si_2O_8$), and as this increases it graduates through oligoclase-albite to oligoclase (cf. p. 332).

**Var.**—*Ordinary.* In crystals and massive. The crystals often tabular ∥ *b*. The massive forms are usually nearly pure white, and often show wavy or curved laminæ.

*Peristerite* is a whitish adularia-like albite, slightly iridescent, having G. = 2·626; named from *περιστερά*, *pigeon*, the colors resembling somewhat those of the neck of a pigeon.

*Aventurine* and *moonstone* varieties also occur as under oligoclase.

*Pericline* from the chloritic schists of the Alps is in rather large opaque white crystals, with characteristic elongation in the direction of the $\bar{b}$ axis, as shown in figs. 8, 9, and commonly twinned with this as the twinning axis (pericline law, see above).

*Hyposclerite* is blackish green from Arendal; H. = 5·5; G. = 2·63–2·66; it contains, according to Rammelsberg, 5 p. c. of pyroxene. Named from *ὑπό*, *under*, *σκληρός*, *hard*, with reference to the inferior hardness.

*Cleavelandite* is a white lamellar kind found at Chesterfield, Mass., and similarly elsewhere, and named after Dr. P. Cleaveland (1780 1858), the mineralogist.

*Olafite*, called also oligoclase-albite by Scheerer, is an albite from Snarum, Norway.

*Zygadite* occurs in thin tabular twin crystals. Translucent or milky. Color yellowish white to reddish. G. = 2·511–2·512, Breith. Found with milky quartz, stilbite, and sphalerite, in fissures in argillyte, at Andreasberg in the Harz. It was named from *ζυγάδην*, *in pairs*, or *twinned*. The identity with albite was made probable by Des Cloizeaux (Min., **1**, 326), and further proved by Krenner and Loczka, cf. anal. 13.

*Tschermakite*, Fr. von Kobell. Described as a magnesian oligoclase, but on the basis of an analysis of impure material; later shown to belong with oligoclase-albite. Cf. Hawes, anal. 14, also Pisani and Dx., l. c. From Kjörrestad near Bamle, Norway, where it occurs with quartz and wagnerite (kjerulfine). Named for Prof. G. Tschermak of Vienna.

**Pyr., etc.**—B B. fuses at 4 to a colorless or white glass, imparting an intense yellow to the flame. Not acted upon by acids.

**Obs.**—Albite is a constituent of many crystalline rocks. With hornblende it constitutes *dioryte.* It occurs with orthoclase (or microcline) in much granite, and in such cases is usually distinguishable by its greater whiteness. In perthite (p. 321) it is interlaminated with orthoclase or microcline, and similar aggregations, often on a microscopic scale, are common in many rocks. Albite is common also in gneiss, and sometimes in the crystalline schists. Veins of albitic granite are often repositories of the rarer minerals and of fine crystallizations of gems, including beryl, tourmaline, allanite, columbite, etc. It occurs also in some volcanic rocks, especially in the andesytes, as with allanite at Langenberg, near Heisterbach in the Siebengebirge; similarly at Felsöbánya. Hungary. It is found in disseminated crystals in granular limestone; thus in the limestone (Jura and Trias) of the Col du Bonhomme, near Modane in Savoy; also in microscopic crystals with quartz and orthoclase in limestone at Meylan near Grenoble; in minute crystals in fossil Radiolarians in limestone near Rovegno, Province of Pavia. Italy, also in the limestone itself; in limestone at Bedous, Basses Pyrénées, at the contact with diabase.

Some of the most prominent European localities are in cavities and veins in the granite or granitoid rocks of the Swiss and Austrian Alps, associated with adularia, smoky quartz, chlorite, titanite, apatite, and many rarer species; it is often implanted in parallel position upon the orthoclase. Thus in the St. Gothard region; Roc Tourné near Modane, Savoy; on Mt. Skopi (pericline); Tavetschthal; Schmirn, Tyrol; also Pfitsch, Rauris, the Zillerthal, Kriml, Schneeberg in Passeir in simple crystals. Also in Dauphiné in similar association; on Elba. Also Hirschberg in Silesia; Penig in Saxony; with topaz at Mursinka in the Ural and near Miask in the Ilmen Mts. At the foot of Kasbék in the Caucasus in cavities in granite, the crystals often simple. Cornwall, England; Mourne Mts. in Ireland.

In the United States, in *Maine*, at Paris, with red and blue tourmalines. In *Mass.*, at Chesterfield, with the same minerals, in lamellar masses (cleavelandite), slightly bluish, also fine granular, and rarely in small crystals; at Goshen. In *New Hamp.*, at Acworth and Alstead; at the slide on Tripyramid Mt., White Mts., in small crystals implanted in parallel position upon orthoclase. In *Conn.*, at Haddam, with chrysoberyl, beryl, columbite, and black tourmaline; at the Middletown feldspar quarry, in fine transparent or translucent crystals (fig. 5); at Monroe, a fine granular variety containing beryl; at Branchville, in fine crystals and massive with microcline, and many rare species. In *N. York*, at Granville, Washington Co., white transparent crystals; at Moriah, Essex Co., of a greenish color, with smoky quartz, and resembling green diallage. In *Penn.*, at Unionville, Chester Co., a granular variety is the matrix of the corundum, having the hardness of quartz; it had been taken for indianite. In *Virginia*, at the mica mines near Amelia Court-House in splendid crystallizations. In *Colorado*, in the Pike's Peak region with smoky quartz and amazon stone coating the crystals, also in composite rosettes forming their base. In *California*, Calaveras Co., with native gold and auriferous pyrites.

In Canada, in fine crystals, at the Suffield silver mine, near L. Massawippi, N.E. of L. Memphremagog; at the Lakes of Three Mountains, Clyde, Ottawa Co., Quebec. *Peristerite* occurs in the township of Bathurst, Lanark Co., also on Stoney Lake, Burleigh, Peterborough Co., Ontario.

The name *Albite* is derived from *albus*, white, in allusion to its color, and was given the species by Gahn and Berzelius in 1814.

**Alt.**—Cf. remarks under orthoclase, p. 320.

Occurs as a pseudomorph after spodumene at Branchville, Ct. (cf. p. 368).

**Artif.**—Obtained by Hautefeuille and also by Friedel and Sarasin by methods similar to those employed with orthoclase; by Fouqué and M.-Lévy direct from the fusion of the constituents. Further, the last-mentioned authors have obtained a series of feldspars intermediate between albite and anorthite, as well as these species themselves; also further certain feldspar-like compounds containing barium, strontium, and lead. For a summary of their results and those of others, see Fouqué-Lévy, Synth. Min., pp. 128–150, 1882.

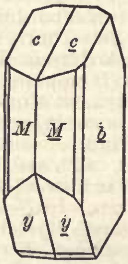
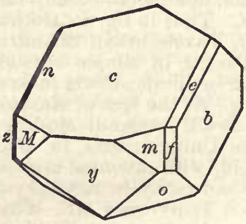
1.

2.



3.



Figs. 1, 2, Vesuvius, Rath. 3, Fine, St. Lawrence Co., N. Y., Pfd.

Twins observed according to the Carlsbad, albite, and pericline laws. Crystals not common. Usually massive, cleavable to compact.

Cleavage: *c* perfect; *b* somewhat less so. Fracture conchoidal to uneven. Brittle. H. = 6–7. G. = 2·65–2·67. Luster vitreous to somewhat pearly or waxy. Color usually whitish, with a faint tinge of grayish green, grayish white, reddish white, greenish, reddish; sometimes aventurine. Transparent, subtranslucent. Optical characters, see pp. 326, 327, and 336.

**Comp., Var.**—Intermediate between albite and anorthite and corresponding to $Ab_6An_1$ to $Ab_2An_1$, but chiefly to $Ab_3An_1$, p. 327.

Analyses, see p. 337; also 5th Ed., pp. 347, 348.

**Var.**—1. *Ordinary.* In crystals or more commonly massive, cleavable. The varieties containing soda up to 10 p. c. are called *oligoclase-albite.*

2. *Aventurine oligoclase,* or *sunstone.* Heliolite *Delameth,* Pierre de Soleil *Fr.* Color

grayish white to reddish gray, usually the latter, with internal yellowish or reddish fire-like reflections proceeding from disseminated crystals of probably either hematite or göthite.

Much oligoclase has a faint greenish tinge and pearly luster, in which it somewhat resembles spodumene, whence the name *soda-spodumene*.

**Pyr., etc.**—B.B. fuses at 3·5 to a clear or enamel-like glass. Not materially acted upon by acids.

**Obs.**—Occurs in porphyry, granite, syenite, serpentine, and also in different eruptive rocks, as andesyte. It is sometimes associated with orthoclase in granite, or other granite-like rock. Among its localities are Danviks-Zoll near Stockholm; Kimito in Finland, forming with quartz and mica the granite containing columbite; Pargas in Finland; Ariége and Arendal, with calcite, epidote, etc., crystals sometimes 2 or 3 in. long; Shaitansk, Ural, greenish, in a gangue of quartz and mica and yellowish white feldspar; in gneiss of the Schwarzwald of Goggenau, north-east of Baden; in syenite of the Vosges; at Albula in the Grisons; in a dark green porphyry at Quenast in Belgium; at Boden near Marienberg; in the amphibolyte of Marienbad, Bohemia; in a green porphyry near Elbingerode in the Harz; Chalanches in Allemont and Bourg d'Oisans; as *sunstone* at Tvedestrand in the Christiania-fiord, Norway; at Hitterö; Lake Baikal; in Donegal, Ireland, in granite, with orthoclase, etc. In lavas and trachyte (*oligoclase-trachyte*) at Teneriffe, and in the Euganean Mts. near Padua; in the domyte (trachyte) of Puy-de-Dôme; in the Eifel; in pumice at Arequipa in Peru; in obsidian, with sanidine, at Zimapan in Mexico.

In the United States, at Fine and Macomb, St. Lawrence Co., N. Y., in good crystals; at Danbury, Ct., with orthoclase and danburite; Haddam, Ct., often transparent, with iolite and black tourmaline; at Orange Summit, N. Hamp., slightly greenish and pearly; at the emery mine, Chester, Mass., granular; at Unionville, Pa., with euphyllite and corundum; Mineral Hill, Delaware Co.; at Bakersville, N. C., in clear glassy masses, showing cleavage but no twinning (see p. 336 and anal. 13, p 337)

Named in 1826 by Breithaupt from ὀλίγος, *little*, and κλάσις, *fracture*. Berzelius had previously (in 1824) recognized it as a new mineral from specimens from Danviks-Zoll; and he afterward named it Natron-spodumen (soda-spodumene).

**Alt., Artif.**—See under Orthoclase and Albite.

**Ref.**—[1] Pogg., **138**, 464, 1869. The angles belong to crystals from Vesuvius whose composition is given in anal. 5, p. 337; other Vesuvian crystals (anal. 16) are referred by Rath to andesine, cf. Pogg., **144**, 225, 1871. [2] Cf. Mlr., Min., 372, 1852. See also Dx., Min., **1**, 312, 1862, who gives 112 ($f^1$) and $1\bar{1}2$ ($d^1$) on sunstone, omitted by Gdt., Index, **2**, 31, 1888.

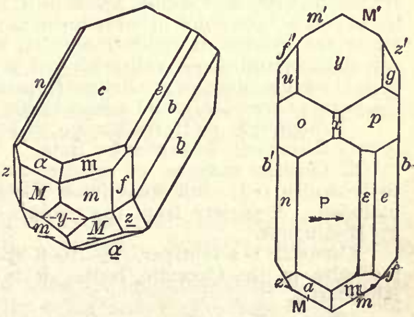
$bx = 87°\ 39'$
$co = {*}57°\ 44'$
$b'o = {*}65°\ 20'$



Figs. 1, 2, Arcuentu, Sardinia, Rath.

Twins observed according to the Carlsbad, albite, and pericline laws. Also[2], tw. axis $\breve{a}$, comp.-face $c$ (f. 1); and since the axial angle is nearly 90°, these twins correspond closely to the Manebach twins of orthoclase. Crystals rare. Usually massive cleavable or granular.

Cleavage: $c$ perfect; $b$ less so; also $M$ sometimes observed. H. = 5–6. G. = 2·68–2·69. Color white, gray, greenish, yellowish, flesh-red. Luster subvitreous to pearly. Optical characters, see pp. 326, 327, and 336.

**Comp.**—Intermediate between albite and anorthite, corresponding to Ab : An in the ratio of 3 : 2, 4 : 3 to 1 : 1, see p. 327.

Analyses, see p. 337; also 5th Ed., pp. 344, 345.

**Pyr., etc.**—Andesine fuses in thin splinters before the blowpipe. Imperfectly soluble in acids.

**Obs.**—Occurs in the Andes, at Marmato, as an ingredient of the rock called *andesyte;* in the porphyry of l'Esterel, Dept. of Var, France; in the syenite of Alsace in the Vosges; white at Servance, red at Coravillers; in the porphyry near Chagey, Haute Saône; at Vapnefiord, Iceland, in honey-yellow transparent crystals; at Baumgarten in Silesia; Bodenmais, Bavaria; Mt. Arcuentu (or Pollice di Oristáno), Sardinia, in a pumice-tuff; at Sanford, Me., with vesuvianite in distinct crystals (anal. 22).

*Saccharite* is granular massive, occurring in veins in serpentine at the chrysoprase mines near Frankenstein, in Silesia; originally referred to andesine, but shown by Lasaulx to be a mixture, Jb. Min., 623, 1878.

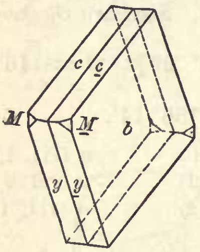
**Ref.**—[1] Mt. Arcuentu, Sardinia, Festschrift Ver. Cassel, 1886; the identification with andesine rests on the determination, $SiO_2 = 60{\cdot}2$ p. c., and the position of the axial plane oblique to *b*, extinction ‖ edge *b/c* (Dx.). [2] Rath, l. c.

**319. Labradorite.** Labradorstein (under Feldspat) *Wern.*, Ueb. Cronst., 149, 1780, Bergm. J., 375, 1789. Labradorstein, Schillernder Quarzspath *Pallas*, Nord. Beiträge, **2**, 233, 1781. Pierre de Labrador *Forst.*, Cat., 82, 1780; *de Lisle*, Crist., **2**, 497, 1783. Labrador Feldspar. Labrador *G. Rose*, Gilb. Ann., **73**, 173, 1823; *Breith.*, Char., 1823. Lime Feldspar. Hafnefjordite, Kalkoligoklas *Forchhammer*, Skand. Nat. Samml. i Stockholm, July 1842, J. pr. Ch **30**, 389, 1842.

Mornite *Thom.*, Ed. N. Phil. J., **13**, 1832. Silicite *Thom.*, Phil. Mag., **22**, 190, 1843. Saussurite pt. Radauit *Breith.*, B. H. Ztg., **25**, 87.

Triclinic. Form near that of andesine, but not accurately known. Cleavage angle $bc = 86° \ 4'$ Tsch. Obermayer[1] has calculated: $\breve{a} : \bar{b} = 0{\cdot}6377 : 1$; also $\alpha = 93° \ 31'$, $\beta = 116° \ 3'$, $\gamma = 89° \ 54\frac{1}{2}'$.

These are based upon the measured angles: $b'c = 93° \ 52'$, $b\lambda = 19° \ 2'$, $bL' = 19° \ 23'$, $b'M = 61° \ 22'$, $cba = 63° \ 57'$. $\lambda = 150$, $L = \bar{1}50$ are cleavage directions.



Forms like those of the other plagioclase species, and twinning common according to the albite law, also the pericline, Carlsbad, Baveno, and Manebach laws; also twinning[2] with tw. axis a normal to ć in the plane *b*. Crystals often very thin tabular ‖ *b*, and rhombic in outline bounded by *cy* or *cx*. Also massive, cleavable or granular; sometimes cryptocrystalline or hornstone-like.

Cleavage: *c* perfect; *b* less so; *M* sometimes distinct; also *l* and *L* sometimes observed, Obermayer; (180), ($1\bar{7}0$) Schrauf, as parting surfaces. H. = 5–6. G. = 2·70–2·72. Luster on *c* pearly, passing into vitreous; elsewhere vitreous or subresinous. Color gray, brown, or greenish; sometimes colorless and glassy; rarely porcelain-white; usually a beautiful change of colors in cleavable varieties, especially ‖ *b*. Streak uncolored. Translucent to subtranslucent. Optical characters, see pp. 326, 327, and 336.

**Var.**—1. *Cleavable.* (*a*) Well crystallized, to (*b*) massive.

Play of colors either wanting, as in some colorless crystals; or pale or deep. Blue and green are the predominant colors; but yellow, fire-red, and pearl-gray also occur. Vogelsang[3] regards the common blue color of labradorite as a polarization-phenomenon due to its lamellar structure. while the golden or reddish schiller, with the other colors, is due to the presence of black acicular microlites and yellowish red microscopic lamellæ, or to the combined effect of these with the blue reflections. Schrauf[3] has examined the inclusions, their position, etc., and given the names *microplakite* and *microphyllite* to two groups of them.

*Hafnefjordite*, or Hafnefiordite, of Forchhammer from the dolerite of Hafnefiord, Iceland, is only labradorite as shown by Rath.

2. *Compact massive*, or *cryptocrystalline; Labradorite-Felsite.* The color sometimes gray to brownish red; but sometimes porcelain-white. Some of the so-called *saussurite* is here included. A variety from the gabbro of Baste in the Radau valley, Harz, is called *Radauite* by Breithaupt.

*Carnatite* is a feldspar, described by Beudant, occurring at the localities of corundum and indianite in the Carnatic, India; it is pronounced by Breithaupt and von Kobell to be labradorite.

**Comp., Var.**—Intermediate between albite and anorthite and corresponding chiefly to Ab : An in a ratio of from 1 : 1 to 1 : 3, p. 327.

For analyses see p. 337; also 5th Ed., p. 342.

The feldspars which lie between labradorite proper and anorthite have been embraced by Tschermak under the name bytownite. The original bytownite of Thomson (Min., **1**, 372, 1836) was a greenish-white feldspathic mineral found in a boulder near Bytown (now Ottawa) in Ontario, Canada. It was analyzed, 1, by Thomson (l. c.) and, 2, by Hunt (Am. J. Sc., **12**, 212, 1851). Tschermak (Ber. Ak. Wien, **50** (1), 590, 1865) has recalculated the latter analysis, rejecting the water; his results are given in 3. Zirkel has shown, however, that the mineral is a mixture; see Min. Mitth., 61, 1871.

| | | $SiO_2$ | $Al_2O_3$ | CaO | MgO | $Na_2O$ | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|
| 1. | G. = 2·80 | $\frac{2}{2}$ 47·57 | 29·65 | 9·06 | 0·40 | 7·60 | 1·98 | $Fe_2O_3$ 3·57 = 99·83 |
| 2. | G. = 2·73 | 47·40 | 30·45 | 14·24 | 0·87 | 2·82 | 2·00 | FeO 0·80, $K_2O$ 0·38 = 98·96 |
| 3. | | 48·82 | 31·49 | 14·67 | — | 2·90 | — | FeO 0·82, $K_2O$ 0·39 = 99·09 |

**Pyr., etc.**—B.B. fuses at 3 to a colorless glass. Decomposed with difficulty by hydrochloric acid, generally leaving a portion of undecomposed mineral.

**Obs.**—Labradorite is an essential constituent of various rocks, especially of the basic kinds and usually associated with some member of the pyroxene or amphibole groups. Thus with hypersthene in hyperyte and noryte, with diallage in gabbro, with some form of pyroxene in diabase, basalt, doleryte, also andesyte, tephryte, etc. Labradorite also occurs in other kinds of lava, and is sometimes found in them in glassy crystals, as in those of Etna, Vesuvius, the Sandwich Islands at Kilauea.

The labradoritic massive rocks are most common among the formations of the Archæan era. Such are part of those of British America, northern New York, Pennsylvania, Arkansas; those of Greenland, Norway, Finland, Sweden, and probably of the Vosges. Being a feldspar containing comparatively little silica, it occurs mainly in rocks which include little or no quartz (free silica) and no orthoclase.

On the coast of Labrador, labradorite is associated with hornblende, hypersthene, and magnetite. It is met with in place at Mille Isles, Chateau Richer, Rawdon, Morin, Abercrombie and elsewhere, in Quebec; and in boulders at Drummond and elsewhere, in Ontario. It occurs abundantly through the central Adirondack region in northern New York; also occasionally in Orange, Lewis, Warren, Scoharie, and Greene Cos.; in the Wichita Mts., Arkansas.

*Silicite* and *mornite* are from Antrim, Ireland.

Labradorite was first brought from the Isle of Paul, on the coast of Labrador, by Mr. Wolfe, a Moravian missionary, about the year 1770, and was called by the early mineralogists Labrador stone (*Labradorstein*), and also chatoyant, opaline, or Labrador feldspar.

**Alt.**—See remarks under orthoclase, p. 320; also Tschermak, Min. Mitth., 269, 1874. The alteration of labradorite is the common source of the zeolites and associated secondary minerals (calcite, datolite, etc.) frequently present in cavities and veins in basic igneous rocks.

**Artif.**—See p. 332.

**Ref.**—[1] Zs. Kr., **7**, 66, 1882. Groth gives the axis $\acute{c}$ = 0·5547.

[2] Rath, Pogg., **144**, 255, 1871. [3] Cf. Reusch, Pogg., 120, 95, 1863 (earlier Brewster, etc.); Vogelsang, Arch. Néerland., **3**, 32, 1868; Schrauf, Ber. Ak. Wien, **60** (1), 996, 1869.

MASKELYNITE *Tschermak*, Ber. Ak. Wien, **65** (1), 127, 1872.

Isometric; form a distorted cube (?). In grains, transparent, colorless, with milky portions arising from alteration. In microscopic sections seen to have a rectangular outline, and shown by optical properties to be isotropic. H. = about 6·5. G. = 2·65 corrected for impurities. B.B. fusible with difficulty to a transparent glass. Analysis, 1*a*, also 1*b*, after deducting a little magnetite present:

| | | $SiO_2$ | $Al_2O_3$ | CaO | $Na_2O$ | $K_2O$ | |
|---|---|---|---|---|---|---|---|
| 1*a*. | G. = 2·71 | $\frac{2}{2}$ 54·3 | 24·8 | 11·1 | 4·9 | 1·2 | $Fe_2O_3$,FeO 4·7, MgO *tr.* = 101·0 |
| 1*b*. | G. = 2·65 | 56·3 | 25·7 | 11·6 | 5·1 | 1·3 | = 100 |

Occurs in the meteorite from Shergotty, near Behar, India; also in other chondrites. Tschermak suggests that this apparently isometric mineral may be in fact a fused feldspar, which seems not improbable (Ber. Ak. Wien, **88** (1), 355, 1883). Groth, on the other hand, is inclined to regard it as an independent species allied to leucite (Tab. Ueb., 136, 1889).

### *Optical Relations of Oligoclase, Andesine, Labradorite.*

The general position of the axes of elasticity and the consequent directions of the light extinction upon the base, *c*, and the brachypinacoid, *b*, of these feldspars are given on pp. 326, 327. The following are special observations.

The following table gives for a series of plagioclase feldspars, oligoclase-albite to bytownite (p. 327) the observed extinction-angles on *b* and *c*, and the angle made by the trace of the rhombic section on *b* with the edge *b/c* (cf. f. 1–3, p. 326); also the percentage of lime (cf. anals., p. 337) and the specific gravity. The observations are taken from Schuster, l. c.; Wiik, Zs. Kr., **2**, 498, 1878; Pfd., Am. J. Sc., **34**, 390, 1887; Schuster and Foullon, l. c.; Bath, Jb. Min., 689, 1876.

| | G. | CaO | Extinction on c | Extinction on b | Rhombic section |

| Labrador | | 10·33 | − 5° 12′ to 5° 24′ | − 17° to 18° 30′ | |
| " | 2·684 | 10·60 (anal. 25) | | − 19° | ± 0° |
| Kamenoi-Brod | | | − 6° 42′ to 6° 54′ | − 19° to 21° | |
| Närodal | | 15·20 (anal. 33) | − 14° 30′ to 20° | − 28° to 32° | − 8° 48′ |
| Vischegrad | | | | | − 10° |

The following are observations by Des Cloizeaux, Bull. Soc. Min., **6**, 89, 1883, **7**, 249, 1884, **8**, 6, 1885. He distinguishes four classes ranging from oligoclase-albite to andesine. The observations quoted give the lime percentage (from complete analyses by Damour, Dirvell, etc.); the extinction-angles on *c* and *b*; the axial angle about the negative bisectrix, and the angle made by the base with the plane, S, normal to the plane of the optic axes.

1. *Abnormal oligoclase.* Ax. plane inclined 83° 10′ to *b*. Plane ⊥ to ax. pl. (S) truncates the acute edge *b*/*c*. Extinction (edge *b*/*c*) + 6° or 7° to 12° on *b*.

2. *Abnormal oligoclase.* Ax. plane ∥ *c* or ⊥ *b*. Extinction-angle with edge *b*/*c* = + 6° to 9°.

3. *Normal oligoclase.* Plane ⊥ ax. pl. truncates obtuse edge *b*/*c* and inclined 98° to 104° on *c*. Ax. pl. cuts *b*, 84° 50′ to 79° 50′. Extinction + 1° to 6° with *b*/*c*.

4. *Andesine.* Plane ⊥ ax. pl. truncates obtuse edge *b*/*c* and inclined 110° to 120° to base. Ax. plane on *b*, 73° 50′ to 63° 50′. Extinction − 1° to 10° to *b*/*c*.

[a] Also larger values.

The glassy oligoclase from Bakersville, N. C., (anal. 13,) has an exceptionally abnormal character: extinction-angle on *c* = + 39° to + 40°, sections ∥ *b* give an optic axis with bar nearly ∥ edge *b*/*c*. Cleavage angle *bc* = 88° 2′, twinning entirely absent. Cf. Penfield, Am. J. Sc., **36**, 324, 1888.

Twins[5]: (1) *Albite law,* tw. pl. and comp.-face *b,* often polysynthetic. (2) *Pericline law,* tw. axis *b̄*, composition-face the rhombic section, whose trace on *b* makes an angle of − 14° to − 18° with the edge *b/c* (f. 2, p. 326). (3) *Carlsbad law,* tw. axis *ć*, the individuals also usually twinned according to law 1. (4) tw. axis[5] ⊥ *ć* in *b* (010).

Crystals usually prismatic ‖ *ć*, less often elongated ‖ *b̄*, like pericline (f. 3). Also massive, cleavable, with granular or coarse lamellar structure.

Cleavage: *c* perfect; *b* somewhat less so. Fracture conchoidal to uneven. Brittle. H. = 6–6·5. G. = 2·74–2·76. Color white, grayish, reddish. Streak uncolored. Transparent to translucent.

Optically −. Ax. pl. nearly ⊥ *e*, and its trace inclined 60° to the edge *c/e* from left above behind to right in front below (Schuster). Extinction-angles on *c*, − 34° to − 42° with edge *b/c*; on *b*, − 35° to − 43°. Dispersion $\rho < v$, also inclined. Axial angles:

$$2H_{a.r} = 84^\circ\ 50', \quad 2H_{a.gr} = 85^\circ\ 24', \quad 2H_{a.bl} = 85^\circ\ 59'.$$

The following table gives the extinction-angles and the position of the rhombic section, with CaO percentage (see anals. below), as observed by Schuster, l. c., Lsx., l. c., and Kikuchi, J. Coll. Sc. Japan, **2**, I, 31, 1888.

| | G. | $Na_2O$ | Extinction angles on *c* | Extinction angles on *b* | Rhombic section |
|---|---|---|---|---|---|
| Vesuvius | 2·763 | 0·47 | −36° 37′ to 37° 22′ | −38° to 39° 44′ | − 16° 2′ |
| Pesmeda | | 1·0 to 1·3 | −37° 30′ | − 38° 24′ | − 17° 54′ |
| Lojo, *Lepolite* | 2·7–2·8 | 1·50 $K_2O$ | | − 35° to 40° | −14° to 15° |
| Etna, *Cyclopite* | 2·682 | 2·32 | − 38° to 40° | − 35° to 36° | |
| Mikaje, Japan | 2·761 | 0·23 | − 38° to 40° | − 40° to 41° | −15° to 17° |

**Comp.**—A silicate of aluminium and calcium, $CaAl_2Si_2O_8$ or $CaO.Al_2O_3.2SiO_2$ = Silica 43·2, alumina 36·7, lime 20·1 = 100. Soda (as $NaAlSi_3O_8$) is usually present in small amount, and as it increases there is a gradual transition through bytownite to labradorite.

**Var.**—*Anorthite* was described from the glassy crystals of Somma; and *christianite* and *biotine* are the same mineral. *Thiorsauite* is the same from Iceland.

*Indianite* is a white, grayish, or reddish granular anorthite from India, where it occurs as the gangue of corundum, first described in 1802 by Count Bournon.

*Amphodelite* is a reddish gray or dingy peach-blossom-red variety, partly in rather large crystals, from Lojo, Finland, and Tunaberg, Sweden. *Lepolite* of Breithaupt (or, as he says, of von Jossa, who sent it to him) comes from Lojo and Orijärvi in Finland, and is the same variety; some of the crystals are 2 inches long. It has been studied crystallographically by Koksharov (Min. Russl., **4**, 234), who finds the crystals highly complex and near Vesuvian anorthite in angle. *Lindsayite* (Linseit, Lindseit) from Orijärvi, Finland, is a somewhat altered variety of lepolite, cf. Wiik, Zs. Kr., **8**, 205, 1883. *Latrobite*, from Amitok Island on the coast of Labrador, is pale rose-red, and closely resembles amphodelite.

*Cyclopite* occurs in small, transparent, and glassy crystals, tabular ‖ *b*, coating cavities in the doleryte of the Cyclopean Islands and near Trezza on Etna. Its identity with anorthite was established by Lasaulx, Zs. Kr., **5**, 326, 1881.

*Anorthoïte* agrees in angles with anorthite but is different in habit, being prismatic ‖ *ă* with *n* and *e* prominent; it shows extinction ‖ *ă* and in a direction normal it appears optically uniaxial. G. = 2·76. A partial analysis gave: $SiO_2$ 37 to 38, $Al_2O_3$ 32·2, CaO 13. The suggestion is made that it may be an anorthite partly altered to scapolite. The single crystal found was embedded in red limestone at the Sillböle iron mine in Finland. Cf. F. J. Wiik, Zs. Kr., **8**, 205, 1883.

*Tankite* occurs in cleavable masses, with *bc* = 86° 20′, of a gray or slightly pinkish color. The original crystals, examined by Dx., are stated to have been brought from Arendal in 1825 by Mr. Tank of Friedrikshold (Dx.). It is (Dx.) a hydrated anorthite, cf. anal. 6.

[a] Incl. $Li_2O$.

**Pyr., etc.**—B.B. fuses at 5 to a colorless glass. Anorthite from Mte. Somma, and indianite from the Carnatic, are decomposed by hydrochloric acid, with separation of gelatinous silica.

**Obs.**—Occurs in some diorytes; occasionally in connection with gabbro and serpentine rocks; in some cases along with corundum; in many volcanic rocks, andesytes, basalts, etc.; as a constituent of some meteorites (Juvenas, Stannern).

Anorthite (*christianite* and *biotine*) occurs at Mount Vesuvius in isolated blocks among the old lavas in the ravines of Monte Somma, associated with sanidine, augite, mica, and vesuvianite; in the Albani Mts.; on the island of Procida near the entrance to the bay of Naples; on the Pesmeda Alp, Monzoni, Tyrol, as a contact mineral; Aranyer Berg, Transylvania, in andesyte; in the Faröer; on Iceland, on the plain of Thiorsâ, Hekla, and elsewhere; near Bogoslovsk in the Ural. In the lava of the island of Miyake, Japan, and also scattered on the lava field in well-defined separate crystals evidently ejected by the volcano; further in the anorthite-basalt of Fusiyama and elsewhere in Japan.

The localities of the special varieties of anorthite have already been mentioned.

*Anorthite* was named in 1823 by Rose from *ανορθός*, *oblique*, the crystallization being triclinic. Bournon's name, *Indianite*, derived from the locality in India, was first published in his Catalogue of the Royal Mineralogical Collection, in the year 1817. The species had been described by him as early as 1802 (l.c.), and his description is remarkably complete for the time, it including, besides physical characters, a chemical analysis by Chenevix, agreeing nearly in essential points with the later by Rose, and quite as well as his, with the true or normal composition of the mineral. Bournon supposed that the grains might be rhombohedral in crystallization; but Brooke, in Phillips' Mineralogy (3d ed.), published in 1823, the year of Rose's publication, announced that there were two cleavages, inclined to one another 84° 45′ and 95° 15′, differing not widely from the same angle as ascertained by Rose. Justice seems to require that Bournon's name should be restored to the species. Beudant, in the first edition of his mineralogy, published in 1824, described indianite in full and called it lime-feldspar, mentioning anorthite only in his index.

*Christianite* was named by Monticelli and Covelli after the prince Christian Frederick of Denmark, who explored Vesuvius with them; *Amphodelite* from *αμφί*, *double*, and *ὀδελός*, *spear*, the crystals being often twinned parallel to 010; *Latrobite*, after C. F. Latrobe, the discoverer of the variety.

**Alt.**—Lindsayite already mentioned is a partially altered anorthite; the same is probably true of sundvikite of A. E. Nordenskiöld, Beskr. Finl. Min., 113, 1855; see 5th Ed., p. 340. Rosite and polyargite of Svanberg, Ak. H. Stockh., 1840, are pinite-like pseudomorphs; rosite is from Aker in Södermanland, and polyargite from Tunaberg, Sweden. See 5th Ed., p. 480.

Crystals of anorthite altered to a saussurite-like substance from Franklin Furnace, N. J., have been described by Roepper (Am. J. Sc., **16**, 364, 1878).

**Artif.**—See albite, p. 331.

**Ref.**—[1] Kk., Min. Russl., **4**, 200, 1862. Cf. also Rose, Gilb. Ann., **73**, 197, 1823. [2] Mlr., Min., 376, 1852. Hbg., Min. Not., **1**, 6, 1856. Dx., Min., **1**, 294, 1862. Kk., l. c. Barsowite *G. Rose*, Pogg., **48**, 567, 1839. Massive; coarse to fine granular. Cleavage in two directions at 90°, extinction parallel to the cleavage. Orthorhombic (or monoclinic). H. = 5·5–6. G. = 2·584 Bauer. Luster more or less pearly. Color white. Optically biaxial.

Composition probably like anorthite, $CaAl_2Si_2O_8$ or $CaO.Al_2O_3.2SiO_2$. Analyses: 1, Varrentrapp, Pogg., **48**, 568. 2, Friederici, Jb. Min., **2**, 71, 1880, after deducting the corundum present.

| | | $SiO_2$ | $Al_2O_3$ | CaO | MgO | Alk. | | |
|---|---|---|---|---|---|---|---|---|
| 1. | $\frac{3}{3}$ | 48·74 | 33·90 | 15·29 | 1·54 | — | = | 99·44 |
| 2. | $\frac{3}{3}$ | 41·54 | 36·59 | 19·82 | — | 2·05 | = | 100 |

B.B. fuses on the edges to a vesicular glass. Gelatinizes readily with hydrochloric acid, especially on heating.

Occurs in boulders in the auriferous sand of Barsovski near Kyshtymsk south of Ekaterinburg in the Ural as the gangue of the blue corundum; the occurrence is similar to that of the indianite which is the gangue of the corundum of the Carnatic. It is often intimately mixed with granular calcite, and incloses also corundum, spinel, and occasionally scales of a yellow mica. Bauer shows that it is chemically identical with anorthite, though apparently different optically and in specific gravity; it may yet prove to be that species, perhaps somewhat altered.

Huronite *Thomson*, Min., **1**, 384, 1836. An impure feldspar approaching anorthite. Occurs in spherical masses in diabase boulders on Drummond Id. in Lake Huron. Structure partly in imperfect folia, and partly granular. H. = 3–3·5; G. = 2·86; luster waxy to pearly: color light yellowish green; subtranslucent. Harrington has examined this mineral and confirmed its relation to anorthite. He gives: H. = 5·5; G. = 2·814; fusibility about 5. An analysis by N. N. Evans gave:

$SiO_2$ 47·07 $Al_2O_3$ 32·49 $Fe_2O_3$ 0·97 CaO 13·30 MgO 0·22 $K_2O$ 2·88 $Na_2O$ 2·03 ign. 2·72 = 101·68

A mineral similar to huronite occurs in place near Sudbury, Ontario; see Harrington, Trans. R. Soc. Canada, 4 (3), 82, 1886.

Mikrotin *G. Tschermak,* Ber. Ak. Wien, 50 (1), 606, 1865. A name proposed for glassy kinds of the plagioclase feldspars, corresponding to the variety sanidine of orthoclase; it is derived from *μικρότης, littleness,* in allusion to the small form in which they commonly appear, as, for example, embedded in volcanic rocks.

Sigterite *C. F. Rammelsberg,* Jb. Min., 2, 71, 1890.

Massive, granular. Cleavage easy, giving a surface with pearly luster; also in traces in a second direction, these regarded as corresponding in position to *c* (001) and *m* (110) of orthoclase. G. = 2·600–2·622. Luster vitreous to pearly. Color gray. Translucent.

Sections parallel to the first direction of cleavage and normal to the second show polysynthetic twinning lamellæ. For the former the angle between the directions of extinction is 7°–9°, i.e., the angle with the edge regarded as corresponding to *c/b* is ± 3½° to 4½°. Sections parallel to the second cleavage show no twinning structure and give an extinction-angle for the edge *c/b* of + 16°. The axial plane is nearly normal to a direction corresponding to *b* and is inclined to *c* in the positive direction (Tenne).

Comp.—$(Na,K)_2Al_2Si_3O_{10}$ or $(Na,K)_2O.Al_2O_3.3SiO_2$. With Na : K = 5 : 1, this requires: Silica 51·5, alumina 29·2, soda 14·8, potash 4·5 = 100.

Anal.—1, Raschig. 2, Rg. Also 3, 4, the same as 1, 2, after deducting, respectively, 3·84 and 6·03 p. c. augite.

| | $SiO_2$ | $Al_2O_3$ | $Na_2O$ | $K_2O$ | |
|---|---|---|---|---|---|
| 1. | 49·71 | 29·54 | 13·31 | 5·00 | FeO 1·34, CaO 0·66, ign. 0·42 = 99·98 |
| 2. | 50·16 | 28·64 | 13·63 | 3·96 | FeO 1·97, CaO 0·98, MgO 0·16, ign. 0·42 = 99·92 |
| 3. | 50·01 | 30·86 | 13·90 | 5·23 | = 100 |
| 4. | 50·54 | 30·64 | 14·58 | 4·24 | = 100 |

Occurs intimately associated with white albite and eudialyte at Sigtesö, in the Langesund-fiord, southern Norway.*

## II. Metasilicates. $RSiO_3$.

Salts of Metasilicic Acid, $H_2SiO_3$; characterized by an oxygen ratio of 2 : 1 for silicon to bases.

The following include all the well-marked groups among the Metasilicates. The Division closes with a number of species, in part of somewhat doubtful composition, forming a transition to the Orthosilicates.

1. **Leucite Group.**
2. **Pyroxene Group.**
3. **Amphibole Group.**
4. **Beryl Group.**
5. **Eudialyte Group.**
6. **Melanocerite Group.**

### 1. Leucite Group. Isometric.

In several respects leucite is allied to the species of the feldspar group, which immediately precede.

321. **Leucite** $KAl(SiO_3)_2$ Isometric at 500°
Pseudo-isometric at ordinary temperatures.

322. **Pollucite** $H_2Cs_4Al_4(SiO_3)_9$ Isometric

---

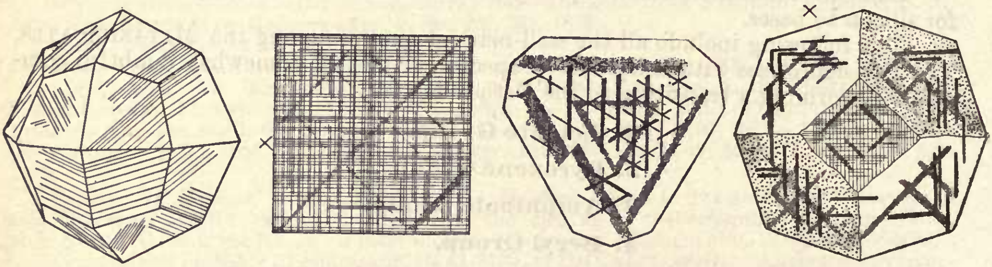
* A later optical investigation by Tenne (Jb. Min., 2, 206, 1891) has shown that the above supposed new species of feldspar is merely an intimate mixture of albite and elæolite. This conclusion finds confirmation in the composition obtained, and is accepted by Rammelsberg. Brögger states further (priv. contr.) that the locality is Sigtesö, not Sigterö.

**321. LEUCITE.** Weisse Granaten, Weisse granat-förmige Schörl-Crystallen (fr. Vesuvius), *J. J. Ferber*, Briefe aus Wälschland, 165, 176, etc., 1773. Basaltes albus polyedrus granatiformis, etc., *v. Born*, Lithoph., **2**, 73. 1775. Schorl blanc *Fr. Trl.* of Ferber. Grenats blancs calcinés (fr. Vesuvius, where called Occhio di Pernice, Rome, etc.) *de Saussure*, J. Phys., **7**, 21, 1776. Œil de Perdrix, Grenats blancs, altérés par une vapeur acide qui ayant dissout le fer a laissé les grénats dans un état de blancheur, *Sage*, Min., **1**, 317, 1777; *de Lisle*, **2**, 330, 1783. Weisse Granaten *Hoffm.*, Bergm. J., 454, 474, 1789. White Garnet. Leucit *Wern.*, Bergm. J., **1**, 489, 1791, Höpfner's Mag. N. Helvet., **4**, 241. Leucite *H.*, J. Mines, **5**, 260, 1799. Amphigène *H.*, Tr., **2**, 1801.

Isometric at 500° C.; pseudo-isometric under ordinary conditions (see below). Commonly in crystals varying in angle but little from the tetragonal trisoctahedron *n* (211, 2-2), with *a* (100, *i-i*), and *d* (110, *i*) sometimes present as subordinate forms. Faces often showing fine striations due to twinning. Also in disseminated grains; rarely massive granular.

Cleavage: *d* (110) very imperfect. Fracture conchoidal. Brittle. H. = 5·5–6. G. = 2·45–2·50. Luster vitreous. Color white, ash-gray or smoke-gray. Streak uncolored. Translucent to opaque. Refractive index: $n_r$ = 1·507 Dx. (1862). Usually shows very feeble double refraction : $\omega = 1·508$, $\epsilon = 1·509$ Dx. (1874).

The anomalous double refraction[1] of leucite was early noted (Brewster, Biot, Dx.) and variously explained. In 1873, Rath, on the basis of careful measurements, referred the seemingly isometric crystals to the tetragonal system; the trapezohedral face 112 being taken as 111, and 211, 121 as 421, 241 respectively; also 101, 011 as 201, 021. Later Weisbach (1880), on the same ground, made them orthorhombic; Mallard, however, referred them (1876), chiefly on optical grounds, to the monoclinic system, and Fouqué and Lévy (1879) to the triclinic. The true symmetry, corresponding to the molecular structure which they possess or tend to possess at ordinary temperatures, is in doubt, but it has been shown (Klein, Pfd.) that at 500° to 600° sections become isotropic; and further (Rosenbusch) that the twinning striations disappear on heating, to reappear again in new position on cooling. Sections ordinarily show twinning lamellæ ‖ *d* (110); in some cases a bisectrix (+) is normal to what corresponds to a cubic face, the axial angle being very small. The structure corresponds in general (Klein) to the interpenetration of three crystals, in twinning position ‖ *d*, which may be equally or unequally developed; or there may be one fundamental individual with inclosed twinning lamellæ (cf. figs. 2–4).



1, Common form, with twinning striations, Rath. 2–4. Sections, showing twinning lamellæ, as seen in polarized light, Klein: 2, section ‖ 001, showing fine tw. lamellæ ‖ 110, also others less numerous and sharp, parallel to two other dodecahedral faces; 3, section ‖ 111, with tw. lamellæ; 4, ‖ cubic face, composite crystal, of three individuals, cf. f. 2.

**Comp.**—A metasilicate of aluminium and potassium, $KAl(SiO_3)_2$ or $K_2O.Al_2O_3.4SiO_2$ = Silica 55·0, alumina 23·5, potash 21·5 = 100.

Soda is present only in small quantities, unless as introduced by alteration; traces of lithium, also of rubidium and cæsium, have been detected.

**Anal.**—1, Rg., Min. Ch., Erg., 151, 1886. 2, Rath, Pogg., **147**, 272, 1872; 3, Id., ibid., Erg., **6**, 209, 1873. 4. Lemberg, Zs. G. Ges., **28**, 537, 1876. 5, E. Scacchi, Rg., l. c., 151, 1886. **6**, Berwerth, Min. Mitth., 66, 1876. 7, Schulze, Jb. Min., **2**, 114, 1880. Also 5th Ed., p. 334.

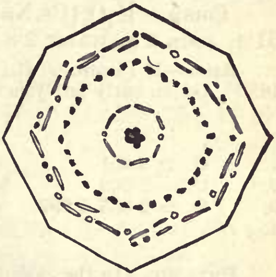
[a] $Fe_2O_3$, *tr.*

Potash, regarded long as an alkali exclusively of the vegetable kingdom, was first found among minerals in this species by Klaproth, whose earliest analysis was made in 1796.

**Pyr., etc.**—B.B. infusible; with cobalt solution gives a blue color (aluminium). Decomposed by hydrochloric acid without gelatinization.

**Obs.**—Leucite belongs peculiarly to the more recent volcanic rocks; thus it occurs in embedded crystals, grains or aggregates of grains, with nephelite in leucite-basalts and leucitytes (leucitophyr or amphigenyte); with nephelite and sanidine in phonolyte, and with plagioclase in leucite-tephrytes. The crystals usually show twinning lamellæ in polarized light, and further are often characterized by the symmetrical arrangement of inclusions (f. 5) of glass, or of microlites of augite, magnetite, etc. Clear glassy crystals occur in ejected volcanic masses or in crevices in lava, as at Mte. Somma.

5.



Section with symmetrical inclusions, Zirkel.

The prominent localities are, first of all, Vesuvius and Mte. Somma, where it is thickly disseminated through the lava in grains, and in large perfect crystals; also in ejected masses. It occurs also near Rome, at Borghetta to the north, and Albano and Frascati to the south; some of the older lavas appear to be almost entirely composed of it. Prominent localities are Capo di Bove, Rocca Monfina, etc. The leucitic lava of the neighborhood of Rome has been used for the last two thousand years, at least, in the formation of mill-stones. Mill-stones of this rock have been discovered in the excavations at Pompeii. Further in leucite-tephryte at Proceno near Lake Bolsena in central Italy. Outside of Italy, it is found about the Laacher See and at several points in the Eifel, as at Olbrück in phonolyte; at Rieden near Andernach; at Meiches in the Vogelsgebirge; in the Kaiserstuhlgebirge; in altered form at several points (see below).

Occurs in Brazil, at Pinhalzinho. At Byrock, near Bourke, and at El Capitan, near Cobar, New South Wales. In basalt on the island Bawean near Java. In leucite-basanyte on the south-east of Mt. Kibo, Kilima-njaro, Equatorial Africa. From the Cerro de las Virgines, Lower California. In the United States it forms a rock in the Green River Basin at the Leucite Hills, Wyoming (Zirkel): also in the Absaroka range, in northwestern Wyoming (Hague, Am. J. Sc., 38, 43, 1889). See also p. 1041.

Named by Werner from λευκός, *white*, in allusion to its color. Haüy's name, *Amphigene*, is of later date, and is from ἄμφι, *both*, and γένος, *kind*, in allusion to the supposed existence of cleavage in two directions, and to his fanciful inference therefrom of two "primitive forms;" it has therefore the best of claims for rejection.

**Alt.**—Feldspar, nephelite, and kaolin occur with the form of leucite, as a result of its alteration. The glassy feldspar pseudomorphs were first announced by Scacchi, and since by Blum. Analcite is also a common alteration-product of leucite. For analyses of altered leucite see Rg., Min. Ch., 443, 1875, also 5th Ed., p. 335.

E. Scacchi has described crystals altered to orthoclase, Rend. Acc. Napoli, Dec., 1884; Sauer, others altered to potash feldspar and muscovite from the Oberwiesenthal in the Erzgebirge, Zs. G. Ges., **37**, 441, 1885. Kunz has described crystals having the form of leucite from Magnet Cove, Ark., and approximating to a potash feldspar in composition, Am. J. Sc., **31**, 74, 1886; these are shown by Williams (cf. p. 426) to consist of orthoclase and elæolite. The phonolyte (tinguayte) of the Serra de Tingua, Brazil, also contains pseudo-crystals of leucite (Hussak, Jb. Min., **1**, 166. 1890).

Lemberg has shown that soda can be readily introduced into the composition of leucite by the action of melting sodium chloride, a soda-leucite (Natronleucit) resulting; while it is possible to change the latter also back to a potash-leucite. Further he has shown that leucite can be resolved into a mixture of sanidine and anorthite or microsommite, or all into andesine. See further Zs. G. Ges., **28**, 611–615, 1876.

**Artif.**—Formed by Fouqué & Lévy, Bull. Soc. Min., **3**. 118, 1880; also an iron leucite by Hautefeuille, C. R., **90**, 313, 378, 1880. Ch. and G. Friedel have obtained leucite in tetragonal forms, optically −, by heating for two days at about 500° a mixture of muscovite with about half its weight of calcined silica and 0·7 of potash; orthoclase and nephelite were obtained at the same time, Bull. Soc. Min., **13**, 134, 182, 1890. See Fouqué-Lévy, Synth. Min., 150–155, 1882.

**322. POLLUCITE.** Pollux *Breith.*, Pogg., **69**, 439, 1846.

Isometric. Observed forms[1]:

*a* (100, *i-i*); *d* (110, *i*); *e*'(210, *i*-2)?; *n* (211, 2-2

Often in cubes with form *n*, also *d* striated transversely; rarely other forms more or less rounded. Also massive.

Cleavage in traces. Fracture conchoidal. Brittle. H. = 6·5. G. = 2·901 Pisani. Luster vitreous and bright on surface of fracture, but sometimes dull and gum-like externally. Colorless. Transparent. Refractive indices: $n_r = 1·515$, $n_y = 1·517$, $n_{bl} = 1·527$ Dx[2].

**Comp.**—$H_2O.(Cs,Na)_2O.Al_2O_3.5SiO_2$ = Silica 47·0, alumina 16·0, cæsium oxide 31·4, soda 2·8, water 2·8 = 100 Rg. Here Cs : Na = 5 : 2. See further, p. 1044.

**Anal.**—1, Pisani, C. R., **58**, 714, 1864. 2, Rg., Ber. Ak. Berlin, 9, 1878. 3, 4, Id., ib., 669, 1880. On an early analysis by Plattner and its interpretation, 5th Ed., p. 249.

| | | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | $Cs_2O$ | $Na_2O$ | $Li_2O$ | $K_2O$ | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|---|---|

| 2. | G. = 2·868 | [48·15] | 16·31 | — | 30·00 | 2·48 | — | 0·47 | 2·59 | = 100 |
| 3. | G. = 2·885–2·897 | 46·48 | 17·24 | — | 30·71 | 2·31 | — | 0·78 | 2·34 | = 99·86 |
| 4. | | — | — | — | 30·53 | 2·19 | — | 0·41 | — | |

**Pyr., etc.**—In the closed tube becomes opaque and yields water, but only at a high temperature. In the forceps whitens, fuses with difficulty, coloring the flame yellow. In hydrochloric acid slowly decomposes, with separation of pulverulent silica.

**Obs.**—Occurs very sparingly in the island of Elba, with petalite (castorite) in cavities in granite. Named from Pollux (the genitive of which is Pollucis), of heathen mythology.

**Ref.**—[1] Corsi, Zs. Kr., **6**, 200, 1881. [2] N. R., 8, 1867.

## 2. Pyroxene Group.

Orthorhombic, Monoclinic, Triclinic.

Composition $RSiO_3$ with R = Ca,Mg,Fe chiefly, also Mn,Zn. Further $RSiO_3$ with $\overset{II}{R}(Fe,Al)_2SiO_6$, less often with $\overset{I}{R}Al(SiO_3)_2$. Rarely including zirconium and titanium, also fluorine.

### α. *Orthorhombic Section.*

| | | | $\breve{a} : \bar{b} : \dot{c}$ | or | $\bar{b} : \breve{a} : \dot{c}$ |
|---|---|---|---|---|---|
| **323.** | **Enstatite** | $MgSiO_3$ | 0·9702 : 1 : 0·5710 | | 1·0307 : 1 : 0·5885 |
| | Bronzite | $(Mg,Fe)SiO_3$ | | | |
| **324.** | **Hypersthene** | $(Fe,Mg)SiO_3$ | 0·9713 : 1 : 0·5704 | | 1·0319 : 1 : 0·5872 |

The second set of axial ratios, with $\breve{a} = 1$, brings out distinctly the similarity of the form to the monoclinic species. This resemblance is exhibited still more clearly if, as suggested by Rath and Tschermak and later adopted by Groth, the monoclinic species are referred to axes having $\beta = 90°$ nearly (see pyroxene); on the other hand this change involves a sacrifice in simplicity of symbols and for other more fundamental reasons is not to be recommended.

### β. *Monoclinic Section.*

| | | | $\grave{a} : \bar{b} : \dot{c}$ | $\beta$ |
|---|---|---|---|---|
| **325.** | **Pyroxene** | | 1·0921 : 1 : 0·5893 | 74° 10′ |

| | or (p. 377) cf. wöhlerite | | 1·0583:1:0·7048 | 90°29′ | 108°49½′ | 90°8′ |

Hiortdahlite also contains fluorine and titanium in small amount.

| | | | $\bar{a} : \breve{b} : \acute{c}$ | $\alpha$ | $\beta$ | $\gamma$ |
|---|---|---|---|---|---|---|
| 335. | **Rhodonite** | $MnSiO_3$ | 1·0729:1:0·6213 | 103°18′ | 108°44′ | 81°39′ |
| | Pajsbergite, Bustamite | $(Mn,Ca)SiO_3$<br>$(Mn,Fe)SiO_3$ | | | | |
| | Fowlerite | $(Mn,Zn,Fe,Ca)SiO_3$ | | | | |

| | | | $\bar{a} : \breve{b} : \acute{c}$ |
|---|---|---|---|
| 336. | **Babingtonite** | $(Ca,Fe,Mn)SiO_3.Fe_2(SiO_3)_3$ | 1·0691 : 0·6308 |

$\alpha = 104°\ 21\tfrac{1}{2}'$ $\beta = 108°\ 31'$ $\gamma = 83°\ 34'$

The Pyroxene Group embraces a number of species which, while falling in different systems—orthorhombic, monoclinic, and triclinic—are yet closely related in form. Thus all have a fundamental prism with an angle of 93° and 87°, parallel to which there is more or less distinct cleavage. Further, the angles in other zones show a greater or less degree of similarity as exhibited in the descriptions which follow. In composition the metasilicates of calcium, magnesium, and ferrous iron are most prominent, while compounds of the form $\overset{II}{R}(Al,\overset{III}{Fe})_2SiO_6$, $\overset{I}{R}Al(SiO_3)_2$ are also important (Tschermak).

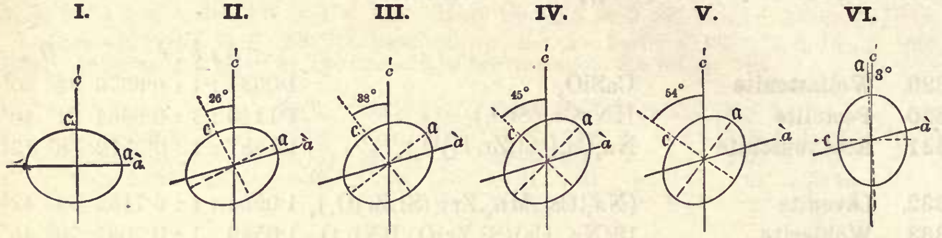
The species of the pyroxene group are closely related in composition to the corresponding species of the amphibole group, which also embraces members in the orthorhombic, monoclinic, and triclinic systems. In a number of cases the same chemical compound appears in each group; furthermore, a change by paramorphism of pyroxene to amphibole is often observed. In form also the two groups are related. Thus we have respectively for the typical monoclinic species:

Pyroxene $\grave{a} : \overset{1}{b} : \acute{c} = 1·0921 : 1 : 0·5893$ $\beta = 74°\ 10'$

Amphibole $\grave{a} : \tfrac{1}{2}\overset{1}{b} : \acute{c} = 1·1022 : 1 : 0·5875$ $\beta = 73°\ 58'$

The relation is further shown in the parallel growth of crystals of monoclinic amphibole upon or about those of pyroxene. This and other related points are illustrated in the pages which follow.

The relation of the prominent members of the Pyroxene Group optically, especially as regards the connection between the position of the axes of light-elasticity and the crystallographic axes is exemplified in the following figures (from Cross, Am. J. Sc., **39**, 359, 1890). A corresponding exhibition of the prominent amphiboles is given under that group.



I, Enstatite, etc. II, Spodumene. III, Diopside, etc. IV, Hedenbergite, Augite. V, Augite. VI, Ægirite (p. 366).

Twins rare: tw. pl.[4] *h* (014), forming twinning lamellæ; also tw. pl. 101 as stellate twins crossing at angles of nearly 60°, sometimes six-rayed (Becke) analogous to the pyroxene twins with tw. pl. 122. Distinct crystals rare, habit prismatic. Usually massive, fibrous or lamellar.

Cleavage: *m* easy. Parting ∥ *b*; also *a*. Fracture uneven. Brittle. H. = 5·5. G. = 3·1–3·3. Luster a little pearly on cleavage-surfaces to vitreous; often metalloidal in the bronzite variety. Color grayish white, yellowish white, greenish white, to olive-green and brown. Pleochroism weak, more marked in varieties relatively rich in iron. Streak uncolored, grayish. Translucent to nearly opaque.

Optically +. Ax.-pl. ∥ *b*. Bx ⊥ *c*. Dispersion $\rho < v$ weak. Axial angle large and variable, increasing with the amount of iron, usually about 90° for FeO = 10 p. c. Axial angles and FeO percentage[5].

| | Aloysthal | Leiperville | Greenland | Balsfiord | Kraubat | Lauterbach |
|---|---|---|---|---|---|---|
| $2H_o$ | 133° 8′ | 123° 38′ | 114° 15′ | 112° 30′ | 106° 51′ | 101° 30′ |
| Fe(Mn)O | 2·76 | 5·77 | 11·14 | 8 42 | 9·80 | 10·62 |

Also, Lévy-Lcx. $\alpha_y = 1·665$ $\beta_y = 1·669$ $\gamma_y = 1·674$ Offret 2V = 70°

**Comp., Var.**—$MgSiO_3$ or $MgO.SiO_2$ = Silica 60, magnesia 40 = 100. Also $(Mg,Fe)SiO_3$ with Mg : Fe = 8 : 1, 6 : 1, 3 : 1, etc.

**Var.**—1. *With little or no iron; Enstatite.* Color white, yellowish, grayish, or greenish white; luster vitreous to pearly; G. = 3·10–3·13. *Chladnite,* Shepardite of Rose, which makes up 90 p. c. of the Bishopville meteorite, belongs here and is the purest kind. *Victorite,* occurring in the Deesa meteoric iron in rosettes of acicular crystals, is similar.

2. *Ferriferous; Bronzite.* Color grayish green to olive-green and brown. Luster of cleavage-surface often adamantine-pearly to submetallic or bronze-like; this, however, is usually of secondary origin and is not essential.

With the increase of iron (above 12 to 14 p. c.) bronzite passes to hypersthene, the optic axial angle changing so that in the latter $\mathfrak{a} = Bx_a$ and $Bx_a \perp a$.

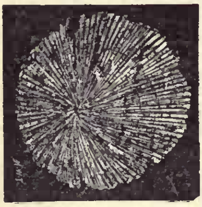
Some of those in this last group properly belong under hypersthene.

**Pyr., etc.**—B.B. almost infusible, being only slightly rounded on the thin edges; F. = 6. Insoluble in hydrochloric acid.

**Obs.**—Enstatite (incl. bronzite) is a common constituent of peridotytes and the serpentines derived from them; it also occurs in crystalline schists. It is often associated in parallel growth with a monoclinic pyroxene, e.g. diallage. A common mineral in meteoric stones often occurring in chondrules with eccentric radiated structure (f. 3). Also obtained in somewhat similar forms from deep-sea dredgings by the "Challenger."

3.



Enstatite Chondrule from the Knyahinya Meteorite.

Occurs near Aloysthal in Moravia, in serpentine; at the W. base of Mt. Bresouars in the Vosges, olive-green, in serpentine; at Kupferberg in Bavaria; at Baste in the Harz (*protobastite*); in the so-called olivine bombs of the Dreiser Weiher in the Eifel; at Grödlitzberg near Liegnitz, Silesia; Ultenthal, Tyrol; also at the other localities mentioned. In immense crystals at the apatite deposits of Kjörrestad near Bamle, Norway, in part altered to a steatic mineral. In the peridotyte associated with the diamond deposits of South Africa.

In the U. S., in New York at the Tilly Foster magnetite mine, Brewster, Putnam Co., with chondrodite. In Penn., at Texas and Castle Rock (?), Delaware Co. At Edwards, N. Y., extensively, more or less completely altered to talc, forming the fibrous mineral which has been called *agalite* (see talc).

Named from ἐνστάτης, an *opponent*, because so refractory. The name *bronzite* has priority, but a bronze luster is not essential, and is far from universal.

**Alt.**—*Bastite* or *Schiller spar* (see p. 351), the original from Baste in the Harz, is an altered bronzite. G. Rose long since pronounced it a result of the alteration of some mineral of the pyroxene group. Enstatite occurs altered to talc as at Edwards, N. Y.; the Bamle mineral approximates to this. At Brewster it occurs altered to serpentine.

**Artif.**—Artificial crystals have been obtained by Daubrée by fusion, also by Fouqué-Lévy, although the monoclinic magnesium silicate (pyroxene) seems to be formed more readily. Cf. Fouqué Lévy, Synth. Min., 110, 1882.

**Ref.**—[1] From the meteorite of Breitenbach, Ber. Ak. Wien, **59** (2), 848, 1869; these crystals gave all the planes in the list except those marked [2] and [3]; see also Weisbach, on bronzite from the Rittersgrün meteorite, Jb. Min., **2**, 253, 1882. It is obvious that no sharp line can be drawn between enstatite and hypersthene. The so-called Breitenbach enstatite (or bronzite) is midway between the two species and perhaps should be regarded as a hypersthene, since it contains 13·6 p. c. of FeO (anal. 20) and is optically *negative*, although the dispersion is $\rho < v$. Dx. gives $2H_{a.r} = 98° 32'$, $2H_{a.y} = 98° 52'$, $2H_{a.gr} = 99° 43'$, Min., **2**, xiv, 1874. Accurate measurements of a true enstatite are thus far wanting; Dx. gives for white artificial crystals, probably pure magnesium silicate (probably a pyroxene?, Fouqué-Lévy), $mm''' = 87° 31'$; also for the victorite of Meunier, $mm''' = 88° 40'$.

[2] Rath, large coarse crystals, in part distorted and monoclinic in symmetry, from Bamle, Norway, Zs. Kr., **1**, 18, 1877. [3] Bkg., bronzite from the Ultenthal, Tyrol, Zs. Kr., **7**, 502, 1883. [4] Becke, Min. Mitth., **7**, 93, 107. [5] Cf. Rosenbusch, Mikr. Phys., 394, 1885.

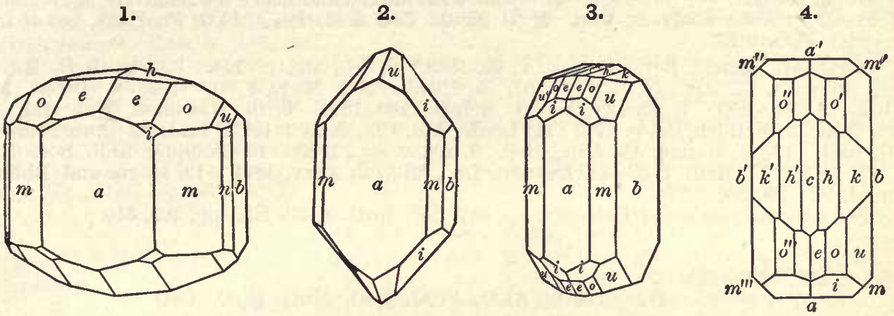

Figs. 1, *Amblystegite,* Laach, Rath. 2, Málnás, Schmidt. 3, 4, Capucin, Mt. Dore, Rath.

Crystals rare, habit prismatic, often tabular ∥ *a*, less often ∥ *b*. Usually foliated massive; sometimes in embedded spherical forms. Twins, see enstatite, p. 346.

Cleavage: *b* perfect; *m* and *a* distinct but interrupted. Fracture uneven. Brittle. H. = 5–6. G. = 3·40–3·50. Luster somewhat pearly on a cleavage-surface, and sometimes metalloidal. Color dark brownish green, grayish black, greenish black, pinchbeck-brown. Streak grayish, brownish gray. Translucent to nearly opaque. Pleochroism often strong, especially in the kinds with high iron percentage; thus ∥ 𝔞 or *ă* brownish red, 𝔟 or *b̄* reddish yellow, 𝔠 or *ċ* green.

Optically —. Ax. pl. ∥ *b*. Bx ⊥ *a*. Dispersion $\rho > v$. Axial angle rather large and variable, diminishing with increase of iron, cf. enstatite, p. 347, and the following from Dx.[4]:

| | Farsund | Finland | Labrador | | | | Mt. Dore |
|---|---|---|---|---|---|---|---|
| $2H_{a.r}$ | 98° 22′ | 92° 10′ | 87° 38′ | 85° 39′ | 77° 29′ | 69° 59′ | 59° 20′ |
| Fe(Mn)O | 15·14 | | | 22·59 | | | 33·6 |

Further, Dx.:

Labrador $2H_{a.r} = 85° 39'$  $\beta_r = 1·69$  ∴ $2V_r = 72° 16'$  $2E_r = 170° 27'$  $[2H_{a.y} = 84° 9'$

Mt. Dore $2E_r = 101° 47'$  $2E_y = 101° 7'$  $2E_{gr} = 100° 58'$

Bodenmais, Becke:

$2H_{a.r} = 86° 36'$  $2H_{a.y} = 85° 48'$  $2H_{a.gr} = 84° 30'$

Labrador, Lévy-Lcx.:

$\alpha = 1·692$  $\beta = 1·702$  $\gamma = 1·705$  $2V = 50°$

Hypersthene often encloses minute tabular scales, usually of a brown color, arranged mostly parallel to the basal plane, also less frequently vertical or inclined 30° to *ċ*; they may be brookite (göthite, hematite), but their true nature is doubtful (cf. Kosmann[3]). They are the cause of the peculiar metalloidal luster or schiller, and are often of secondary origin, being developed along the so-called "solution-planes" of Judd.

**Comp., Var.**—$(Fe,Mg)SiO_3$ with Fe : Mg = 1 : 3 (FeO = 16·7 p. c.), 1 : 2 (FeO = 21·7 p. c.) to nearly 1 : 1 (FeO = 31·0 p. c.). Alumina is sometimes present (up to 10 p. c.) and the composition then approximates to the aluminous pyroxenes.

Of the orthorhombic magnesium-iron metasilicates those with FeO > 12 to 15 p. c. are usually to be classed with hypersthene, which is further characterized by being optically negative and having dispersion $\rho > v$.

**Var.**—*Ordinary.*—In lamellar masses, usually exhibiting the characteristic schiller (see above); less often in distinct crystals.

*Amblystegite* from the Laacher See, first described as an independent species, was shown by Rath to be identical with hypersthene after the form of the latter had been determined by Lang. Judd has proposed to retain the name for those kinds which lack the characters of the original typical hypersthene (Geol. Mag., 2, 173, 1885).

*Szaboite* occurs in thin tabular crystals (‖ *b*); it was first described as triclinic and a relation to babingtonite suggested, but its identity with hypersthene was later fixed by Lasaulx (l.c.) and Fr. Koch, Zs. Kr., 10, 100, 1884. It is somewhat altered and hence the relatively large amount of $Fe_2O_3$ in some analyses; thus: MgO 22·82, FeO 8·46, $Fe_2O_3$ 12·69 Fr. Koch, but of fresh material FeO 19·70.

**Pyr., etc.**—B.B. fuses to a black enamel, and on charcoal yields a magnetic mass; fuses more easily with increasing amount of iron. Partially decomposed by hydrochloric acid.

**Obs.**—Hypersthene, associated with a triclinic feldspar (labradorite), is common in certain granular eruptive rocks, as noryte, hyperyte, gabbro, also in some andesytes (*hypersthene-andesyte*) a rock recently shown to occur rather extensively in widely separated regions.

It occurs at Isle St. Paul, Labrador; at Chateau Richer and St. Adèle, Mille Isles, Canada, grayish black and brown, with the laminæ curved; at the Isle of Skye; in Greenland; at Farsund and elsewhere in Norway; Elfdalen in Sweden; at Romsås in spherical form in the "Kugelgabbro;" Penig in Saxony; Ronsberg in Bohemia; the Tyrol; Neurode in Silesia; in Thuringia; the Fichtelgebirge; Voigtland; Bodenmais, Bavaria (Becke). In the trachyte of Demavend, Persia (Blaas).

*Amblystegite* is from the Laacher See. *Szaboite* occurs with pseudobrookite and tridymite, in cavities in the andesyte of the Aranyer Berg, Transylvania; also on Mte. Calvario (Etna), near Biancaville, Sicily; also Riveau-Grand, Monte Dore, Puy-de-Dôme. Named after Prof. J. Szabó, of Budapest. *Ficinite* of Kenngott (not the original ficinite) is hypersthene from Bodenmais (Becke).

In the norytes of the Cortlandt region on the Hudson River, N. Y. (G. H. Williams, Am. J. Sc., 33, 137, 1887). Also common with labradorite in the Adirondack Archæan region of northern New York and northward in Canada. In the hypersthene-andesytes of Mt. Shasta, California; Buffalo Peaks, Colorado, and other points.

*Germarite* Breithaupt is a slightly altered hypersthene, Dx., N. R., 61, 1867.

*Hypersthene* is named from ὑπέρ and σθένος, *very strong*, or *tough*. *Amblystegite* is named from ἀμβλύς, *blunt*, στέγη, *roof*, in allusion to the form of the crystals (f. 1).

**Ref.**—[1] From Laach, amblystegite, Pogg., 138, 529, 1869, 152, 27, 1874. Crystals from the Capucin rocks, Mont Dore, gave similar results, Dx., Min., 2, xv, 1874. [2] Becke, Bodenmais, Min. Mitth., 3, 60, 1880. Cf. also Blaas, Persia, Min. Mitth., 3, 479, 1881; Oebbeke, Mt. Dore, Bull. Soc. Min., **8**, 50, 1885; Schmidt, Málnás, Zs. Kr., **10**, 210, 1885, and Mt. Pokhausz, near Schemnitz, Hungary, ib., **12**, 97, 1886; Busz, Mt. Dore, Zs. Kr., **17**, 554, 1890. Cf. also enstatite (p. 346), since the two species can hardly be sharply separated. [3] Kosmann, Jb. Min., 532, 1869, 501, 1871. [4] Dx., N. R., 63, 1867; Min., **2**, xv, 1874.

The following are alteration products of enstatite-hypersthene.

**DIACLASITE.** Gelber Schillerspath *Freiesleben*, Schill. Foss. Baste, 13, 1794. Talkartiger Hornblende, *Hausm.*, Nordd. Beitr. B. H., **1**, 15, 1806. Diaklas *Breith.*, Char., 58, 1823. Diaklasit *Hausm.*, Handb., 498, 1847.

A partially altered enstatite (bronzite) in which the optic axial plane has become ‖ *a* instead of ‖ *b*; it contains several per cent of water. Form and cleavage like enstatite. H. = 3·5–4. G. = 2·8; 3·054 Köhler. Luster pearly and metalloidal on a cleavage-face. Color brass-yellow, greenish gray. Streak greenish gray or nearly uncolored. Transparent in thin laminæ, translucent. Feel somewhat greasy.

Analyses.—1, Köhler, Pogg., **13**, 101, 1828. 2, A. Streng, B. H. Ztg., **23**, 54, 1864. 3, Sander, Rg., Min. Ch., 385, 1875.

In crystals or foliated masses embedded in serpentine rock at Baste near Harzburg; also from the gneiss mountains of Guadarrama, Spain.

**BASTITE, or SCHILLER SPAR.** Talkart *v. Trebra*, Erfahr. Inn. Gebirge, 97, 1785. Schillerspath (fr. Baste) *Heyer*, Crell's Ann., 1786, **1**, 335, **2**, 147. Schillerstein *Wern.*, 1800, Ludw., 50, 1803. Diallage pt. *H.*, Tr., 1801. Metalloidal diallage pt. Bastit *Haid.*, Handb., 523, 1845.

An altered enstatite (or bronzite) having approximately the composition of serpentine. It occurs in foliated form in certain granular eruptive rocks and is characterized by a bronze-like metalloidal luster or schiller on the chief cleavage-face (*b*), which "schillerization" (Judd, cf. Q. J. G. Soc., **41**, 408, 1865, and Min. Mag., **7**, 81, 1886) is undoubtedly of secondary origin. H. = 3·5–4. G. = 2·5–2·7. Color leek-green to olive- and pistachio-green, and pinchbeck-brown. Pleochroism not marked. Optically −. Double refraction weak. Ax. pl. ‖ *a* (hence normal to that of enstatite). Bx ⊥ *b*. Dispersion $\rho > v$.

The original bastite was from Baste near Harzburg in the Harz; also from Todtmoos in the Schwarzwald.

Anal.—1, 2, Köhler, Pogg., **11**, 192, 1827. 3, W. Hetzer C. E. Weiss, Pogg., **119**, 446, 1863.

[a] With 2·37 $Cr_2O_3$ [b] With some $Cr_2O_3$.

In the closed tube affords water. B.B. becomes brown and is slightly rounded on the thin edges. With borax reactions of iron. Imperfectly decomposed by hydrochloric acid, completely so by sulphuric acid. A mineral resembling schiller spar occurs in serpentine in Middletown, Delaware Co., Pa. Some altered monoclinic pyroxene may be included in what is called schiller spar.

**PHÄSTINE.** Phästin *Breith.*, Char., 29, 180, 1823, 115, 1832. Resembles somewhat schiller spar, and, according to Breithaupt, is altered bronzite. It is foliated, but the cleavage is not very easy; H. = 1–1½; G. = 2·825; luster pearly; color yellowish gray; feel greasy, talc-like. It is from Kupferberg in the Fichtelgebirge, and occurs distributed through serpentine.

---

**PECKHAMITE** *J. L. Smith*, Am. J. Sc., **19**, 462, **20**, 136, 1880.

Occurs in rounded nodules. Cleavage distinct. G. = 3·23. Luster greasy, opalescent. Color light greenish yellow. Composition, $2(Mg,Fe)SiO_3.(Mg,Fe)SiO_4$. Anal.—1, on 0·1 gr., 2, on 0·35 gr.

| | $SiO_2$ | FeO | MgO |
|---|---|---|---|
| 1. | 49·50 | 15·88 | 33·01 = 98·39 |
| 2. | 49·59 | 17·01 | 32·51 = 99·11 |

From the meteorite of Estherville, Emmet Co., Iowa, which fell May 10, 1879. Also from the Logrono and Sierra de Chaco meteorites (Meunier). Named after Prof. S. F. Peckham.

Whether peckhamite is to be regarded as an independent species, or the result of a mixture of enstatite and chrysolite as has been urged, is uncertain.

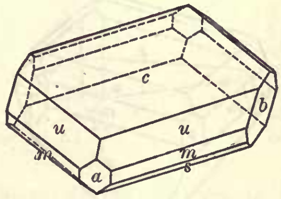
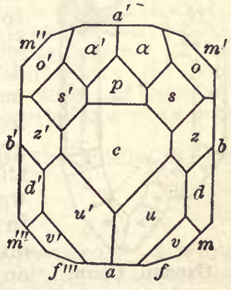


Figs 1, 2, Russell, N. Y. 3, Pierrepont, N. Y. 4, Gouverneur, N. Y. 5, 7, *Diopside*, De Kalb, N. Y. 6, Rossie, N. Y. 1–7, Pfd. 8, Monroe, N. Y. 9, Warwick, N. Y.

Twins[10]: tw. pl. (1) *a*, contact-twins, common (fig. 18), sometimes polysynthetic. (2) *c*, as twinning lamellæ producing striations and pseudo-cleavage or parting ∥ *c*; very common, often of unquestioned secondary origin; also capable of being produced artificially. (3) *y* (101) cruciform-twins, not common, f. 20. (4) *W* ($\bar{1}22$) contact-twins or penetration- and cruciform-twins, the vertical axes crossing at angles of nearly 60° ($bW = 59°\ 29'$, and since $a'W = 90°\ 9'$, the faces *a* and $\underline{a}$ fall nearly in a plane; sometimes repeated as a six-rayed star (f. 21).

10.



Crystals usually prismatic in habit, often short and thick, and either a square prism (*a*, *b* prominent), or nearly square (93°, 87°) with *m* predominating; sometimes a nearly symmetrical 8-sided prism with *a*, *b*, *m*. Often coarsely lamellar, ∥ *c* or *a*. Also granular, coarse or fine; rarely fibrous or columnar.

Occasionally hemihedral, only the planes at an extremity of the vertical axis being present, and the habit then apparently hemimorphic as in f. 22 and f. 19, the latter a twin. Cf. G. H. Williams[8].

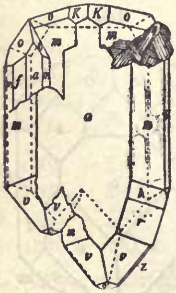
22.



Canaan, Conn.

Cleavage: *m* sometimes rather perfect, but interrupted, often only observed in thin sections ⊥ *c*. Parting ∥ *c*, due to twinning, often very prominent, especially in large crystals and lamellar masses; also ∥ *a* less distinct and not so common. Fracture uneven to conchoidal. Brittle. H. = 5–6. G. ≒ 3·2 –3·6, varying with the composition. Luster vitreous inclining to resinous; often dull; sometimes pearly ∥ *c* in kinds showing parting. Color usually green of various dull shades, varying from nearly colorless, white, or grayish white to brown and black; rarely bright green, as in kinds containing chromium. Streak white to gray and grayish green. Transparent to opaque. Pleochroism usually weak, even in dark colored varieties; sometimes marked, especially in violet-brown kinds containing titanium. Pyro-electrically + on *a* (cooling), and − on *b* for Ala crystals, but − on *a* and + on *b* for Tyrol; an indistinct opposite polarity between the extremities of the vertical axis was noted in one case, Hankel.

Optically +. Double refraction strong. Ax. pl. ∥ *b*. $Bx_a \wedge \dot{c} = \mathfrak{c} \wedge \dot{c} = +36°$ to $+52°$, or $c\mathfrak{c} = 20°$ to $36°$, the angle in general increasing with amount of iron (see below). Axial angles for diopside from Ala, Dx.:

$$\alpha_y = 1{\cdot}6727 \quad \beta_y = 1{\cdot}6798 \quad \gamma_y = 1{\cdot}7026 \quad \therefore 2V_y = 58° 59' \quad 2E_y = 111° 34'$$

Measured, $2E_r = 111° 40'$ $2E_y = 111° 20'$ $2E_{bl} = 110° 51'$

Refractive indices, Heusser:

$$\beta_r = 1{\cdot}67810 \qquad \beta_y = 1{\cdot}68135 \qquad \beta_{gr} = 1{\cdot}68567 \qquad \beta_{bl} = 1{\cdot}69372$$

See also beyond under diopside, etc.

The connection between the position of the axes of elasticity and the composition (see further analyses beyond) is exhibited in the following tables, chiefly from Doelter, also Wiik.

| | FeO | $Bx_a \wedge \dot{c}$ | | FeO | $Bx_a \wedge \dot{c}$ |

**Comp., Var.**—For the most part a normal metasilicate, $RSiO_3$, of various bivalent or less frequently univalent metals, chiefly calcium and magnesium, also iron, less often manganese and zinc. The alkali metals potassium and sodium present rarely, except in very small amount. Also in certain varieties containing the trivalent metals aluminium, ferric iron, and manganese. These varieties may be most simply considered as molecular compounds of $Ca(Mg,Fe)Si_2O_6$ and $(Mg,Fe)(Al,Fe)_2SiO_6$, as suggested by Tschermak. Chromium is sometimes present in small amount; also titanium replacing silicon.

The name *Pyroxene* is from πῦρ, *fire*, and ξένος, *stranger*, and records Haüy's idea that the mineral was, as he expresses it, "a stranger in the domain of fire," whereas, in fact, it is, next to the feldspars, the most universal constituent of igneous rocks. This error, however, was more than counterbalanced by Haüy's discovery of the true crystallographic distinction of the species, which led him to bring together, under this one name, what Werner and others had regarded as distinct species. The name, therefore, is properly the name of the species as a whole, while *Augite* is only entitled to be used for one of its varieties.

The varieties are numerous and depend upon variations in composition chiefly; the more prominent of the varieties properly rank as sub-species.

## I. *Containing little or no Aluminium.*

DIOPSIDE. Malacolite, Alalite. *Calcium-magnesium pyroxene.* Formula $CaMg(SiO_3)_2$ = Silica 55·6, lime 25·9, magnesia 18·5 = 100. Color white, yellowish, grayish white to pale green, and finally to dark green and nearly black; sometimes transparent and colorless. In prismatic crystals, often slender; also granular and columnar to lamellar massive. G. = 3·2–3·38. $Bx_a \wedge \dot{c} = +36°$ and upwards. Iron is present usually in small amount as noted below, and the amount increases as it graduates toward true hedenbergite, see further below.

Flink gives for the five varieties of diopside from Nordmark the following optical constants; see analyses 10–15 beyond, and for the axial ratios see Ref.[1].

| $Bx_a \wedge \dot{c}$ | $2V_r$ | $2V_y$ | $2V_{gr}$ | $\beta_r$ | $\beta_y$ | $\beta_{gr}$ |
|---|---|---|---|---|---|---|
| +38° 3½′ | 59° 9′ | 58° 52′ | 58° 40′ | 1·68978 | 1·69359 | 1·69869 |
| 38° 45′ | 59° 9′ | 58° 57′ | 58° 46′ | 1·69133 | 1·69593 | 1·69781 |
| 39° 1′ | 59° 6½′ | 58° 56½′ | 58° 47′ | 1·68889 | 1·69588 | 1·70029 |
| 41° 41′ | 59° 18′ | 59° 11′ | 59° 6′ | 1·70055 | 1·70467 | 1·71062 |
| 44° 38½′ | 60° 44½′ | 60° 36′ | 60° 29′ | 1·71655 | 1·72428 | 1·72983 |

The following belong here:

*Chrome-diopside*, a variety containing chromium in small amount, often of a bright green; from the localities mentioned under analyses 33–40.

*Malacolite*, as originally used, included a bluish gray, grayish green, and whitish translucent variety from Sala, Sweden.

*Alalite* occurs in broad right-angled prisms, colorless to faint greenish or clear green, usually striated longitudinally, and came originally from the Mussa Alp in the Ala valley, Piedmont. *Mussite* is white, grayish white, and apple-green (according to Bonvolsin's original description), and occurs in prismatic implanted crystals, and also in masses made up of aggregated crystals. Named from the same locality, the Mussa Alp.

*Traversellite*, from Traversella, is in similar long glassy crystals, usually rectangular (*a*, *b*), much striated longitudinally, often clear green at one end and colorless at the other; prismatic cleavage perfect.

*Canaanite* is a grayish white or bluish white pyroxene rock occurring with dolomite at Canaan, Conn.; it has been referred to scapolite. Pyroxene in large white crystals is common in the region (f. 22); their composition, according to an analysis by M. D. Munn (priv. contr.) is: ⅔ $SiO_2$ 55·05, CaO 31·35, MgO 12·53, $Al_2O_3,Fe_2O_3$ 1·07 = 100; G. = 3·33. Cf. 5th Ed., p. 803.

*Lavrovite* is a pyroxene, colored green by vanadium, from the neighborhood of Lake Baikal in eastern Siberia. In coarse granular masses with quartz, and also in small imperfect crystals. Cleavage affords the prism 87° 7′; and there is the usual lamination from compound structure parallel to *c*. The color is fine emerald-green. Cf. anal. 50, and Kk., Min. Russl., 6, 206.

*Diopside* is named from *δις*, *twice* or *double*, and *ὄψις*, *appearance*. *Malacolite* is from *μαλακός*, *soft*, because softer than feldspar, with which it was associated.

HEDENBERGITE. *Calcium-iron pyroxene*. Formula $CaFe(SiO_3)_2$ = Silica 48·4, iron protoxide 29·4, lime 22·2 = 100. Color black. In crystals, and also lamellar massive. G. = 3·5–3·58. $Bx_a \wedge \dot{c} = +48°$. Manganese is present in *manganhedenbergite* to 6·5 p. c., see anal. 45, below. Color grayish green. G. = 3·55. Named after the Swedish chemist, Ludwig Hedenberg, who first analyzed and described the mineral.

Between the two extremes, diopside and hedenbergite, there are numerous transitions conforming to the formula $Ca(Mg,Fe)Si_2O_6$. As the amount of iron increases the color changes from light to dark green to nearly black, the specific gravity increases from 3·2 to 3·6, and the angle $Bx_a \wedge \dot{c}$ also from 36° to 48°.

The following are varieties, coming under these two sub-species, based in part upon structure, in part on peculiarities of composition.

SALITE. Sahlite. Color grayish green to deep green and black; sometimes grayish and yellowish white. In crystals; also cleavable and granular massive. G. = 3·25–3·4. Named from Sala in Sweden, one of its localities, where the mineral occurs in masses of a grayish green color, having a perfect parting ‖ *c*.

*Baikalite* is a dark dingy green variety, in crystals, with parting like the preceding. Named from Lake Baikal, in Siberia, near which it occurs.

*Protheite* is somber-green, in crystals, and approaches fassaite; from the Zillerthal in Tyrol.

*Funkite* is dark olive-green coccolite from Boksäter in Göthland, having a larger percentage of Fe than Mg.

*Lotalite* from Lotala, Finland, in black lamellar masses, is near hedenbergite.

VIOLAN *Breithaupt*, J. pr. Ch., 15. 321, 1838. Occasionally in prismatic crystals, affording (Dx , Min., 1, 66, 1862, N. R., 183, 1867) the angles and the planes (in the prismatic zone) of pyroxene, also the prismatic cleavage. Usually lamellar massive, sometimes fibrous. H. = 6. G. = 3·233.

Luster waxy. Color dark violet-blue. Translucent, but in thin plates transparent. Optically +, and $Bx_o$ inclined to *a* as in diopside. Anal.—1, Damour, Dx., Min., **1**, 66, 1862 (impure material ?). 2, Pisani, Dx., N. R., 184, 1867. 3, Schluttig, Inaug. Diss., Leipzig, Groitzsch, 17, 1884, as recalc. by Grünhut, Zs. Kr., **13**, 74, 1887.

| | | $SiO_2$ | $Al_2O_3$ | FeO | MnO | CaO | MgO | $Na_2O$ | |
|---|---|---|---|---|---|---|---|---|---|
| 1. | G. = 3·233 | 56·11 | 9·04 | 2·46 | 2·54 | 13·62 | 10·40 | 5·63 | = 99·80 |
| 2. | G. = 3·21 | 50·30 | 2·31 | 4·15 | 0·76 | 22·35 | 14·80 | 5·03 | $H_2O$ 0·30 = 100 |
| 3. | G. = 3·231 | ⅔ 52·02 | 2·60 | 1·19[a] | 2·87 | 22·94 | 15·18 | 5·69[b] | = 102·49 |

[a] Incl. (Ni,Co)O 0·39. [b] Incl. $K_2O$ 0·75.

Occurs in small seams with white quartz, white fibrous tremolite spotted violet with manganese, greenovite and manganesian epidote, in the braunite of St. Marcel, in the valley of Aosta, Piedmont. Named from its color.

ANTHOCHROITE *L. J. Igelström*, Jb. Min., **2**, 36, 1889. Probably identical with violan. Occurs in grains embedded in limestone and in thin veins. H. = 5–6. Color rose-red to pale violet. Analysis gave: $SiO_2$ 51·6, MnO 3·4, MgO 13·5, CaO 23·3, $Al_2O_3$,$Fe_2O_3$ 1·4, alk. [6·8] = 100. Occurs associated with braunite, manganesian garnet, epidote, vesuvianite at Jakobsberg, Wermland, Sweden. Named from ανθος, *flower*, and χροα, *color*.

*Asteroite* L. J. Igelström, B. H. Ztg., **29**, 8, 1870, is a stellate radiated pyroxene, from Nordmark, in Sweden. Color ash-gray to white; luster silky; opaque, becoming bronze color on exposure. Anal.—$SiO_2$ 48·48, FeO 22·24, MnO 4·12, CaO 17·00, MgO 4·18, ign. 2·83 = 98·85.

COCCOLITE. A granular variety, sometimes as indistinct crystals embedded in calcite, also forming loosely coherent to compact granular aggregates. Color varying from white to pale green to dark green, and then containing considerable iron; the latter the original coccolite. Named from κόκκος, a *grain*.

DIALLAGE. Lamellar or thin-foliated pyroxene, characterized by a fine lamellar structure and parting ‖ *a*, with also parting ‖ *b*, and less often ‖ *c*. Also a fibrous structure ‖ $\dot{c}$. Twinning ‖ *a*, often polysynthetic; interlamination with an orthorhombic pyroxene common. Color grayish green to bright grass-green, and deep green; also brown. Luster of surface *a* often pearly, sometimes metalloidal or exhibiting schiller and resembling bronzite, from the presence of microscopic inclusions of secondary origin (cf. Judd, ref. see bastite, p. 351). $Bx_a \wedge \dot{c} =$ +39 to 40°. H = 4; G. = 3·2–3·35. In composition near diopside, but often containing alumina and sometimes in considerable amount, then properly to be classed with the augites (cf. anal. 51–65). Often changed to amphibole; see smaragdite, p. 389, and uralite, p. 390.

Named from διαλλαγή, *difference*, in allusion to the dissimilar cleavages or planes of fracture. This is the characteristic pyroxene of gabbro, and other related rocks.

*Hudsonite* is a lamellar massive kind, color black, often with a bronze tarnish. G. = 3·5, Beck; 3·43–3·46, Brewer. Contains lime and ferrous iron, with but little magnesia. Named from the Hudson river, in the vicinity of which it occurs, in Cornwall, Orange Co., N. Y.

OMPHACITE. Omphazit [fr. Baireuth] *Wern.*. Hoffm. Min., **2**, 2, 302, 1812; *Breith.*, ib., **4**, 2. 125, 1817, Handb., 612, 1841, B. H. Ztg., **24**, 365, 397, 1865. The granular to foliated pyroxenic constituent of the garnet-rock called eclogyte, often interlaminated with amphibole (smaragdite); cleavage as with pyroxene. H. = 5–6. G. = 3·2–3·3. Luster vitreous to silky. Color grass-green. Anal.—1–5, J. Fikenscher, B. H. Ztg., **24**, 397, 1865. 6, Luedecke, Zs. G. Ges., **28**, 259, 1876.

| | G. | $SiO_2$ | $Al_2O_3$ | FeO | MgO | CaO | $Na_2O$ | $K_2O$ | ign. | |

Occurs near Hof in Bavaria; at Pacher in Styria. Also a similar mineral (diallage) in the glaucoplane schists of the island Syra (Luedecke). Schrauf gives the name to the "chromdiopsid" of anal. 36, beyond. The name *Omphacite* is from ὄμφαξ, *an unripe grape*, alluding to the color; it is among the names of green stones mentioned by Pliny.

SCHEFFERITE. A manganese pyroxene, sometimes also containing much iron (iron-schefferite, Eisenschefferit *Flink*). Flink gives the composition of the Långban mineral (anal. 46) as corresponding to $6CaMgSi_2O_6.MgFeSi_2O_6.Mn_2Si_2O_6$.

In crystals, sometimes tabular ‖ *c* (f. 13), also with *p* ($\bar{1}01$) prominent, more often elongated in the direction of the zone *b* : *p* ($\bar{1}01$), as in f. 14; very rarely prismatic, ‖ $\dot{c}$. Twins, with *a* as tw. pl., very common. Axial ratio as given beyond, Ref. [1]. Also crystalline, massive. Cleavage prismatic, very distinct. Color yellowish brown to reddish brown. Optically +. $Bx_a \wedge \dot{c} = \mathfrak{c} \wedge \dot{c} = 44° 25\frac{1}{2}'$. $2V_y = 65° 3'$. Named after the Swedish chemist (1710–1759).

The iron-schefferite from Pajsberg (anal. 47) is black in color and has the axial ratio given beyond. $\mathfrak{c} \wedge \dot{c} = +49°$ to 59° for different zones in the same crystal. The brown iron-schefferite from Långban (anal. 48) has $\mathfrak{c} \wedge \dot{c} = 69° 3'$. It resembles garnet in appearance.

**Jeffersonite.** A manganese-zinc pyroxene (see anal. 49). In coarse crystals sometimes very large; they are like ordinary pyroxene in habit. Edges rounded and faces uneven and apparently corroded. G. = 3·63. Color greenish black, on the exposed surface chocolate-brown. $Bx_a \wedge \dot{c} = 53° 32'$. $2H_{a.y} = 84° 32'$ Dx., Min., **2**, XIX, 1874. Named after Mr. Jefferson.

According to the view of R. Fritz Gaertner the zinc shown in the analysis is to be explained as due to enclosed zincite and the manganèse to franklinite, but this needs confirmation; Pisani's analysis (49) was made on the crystals examined optically by Dx.

## II. *Aluminous.*

**Augite.** *Aluminous pyroxene.* Composition chiefly $CaMgSi_2O_6$ with $(Mg,Fe)(Al,Fe)_2SiO_6$, and occasionally also containing alkalies. Here belong:

*a.* **Leucaugite.** Color white or grayish. Contains alumina, with lime and magnesia, and little or no iron. Looks like diopside. H. = 6·5; G. = 3·19, Hunt. Named from λευκός, *white.*

*b.* **Fassaite,** or *Pyrgom.* Includes the pale to dark, sometimes deep-green crystals, or pistachio-green and then resembling epidote. The aluminous kinds of diallage also belong here. Named from the locality in the Fassathal, Tyrol. *Pyrgom* is from πύργωμα, *a tower.*

*c.* **Augite.** Includes the greenish or brownish black and black kinds, occurring mostly in eruptive rocks. It is usually in short prismatic crystals, thick and stout, or tabular ‖ *a*; often twins. Ferric iron is here present, in relatively large amount, and the angle $Bx_a \wedge \dot{c}$ becomes + 50° to 52°. Named from αὐγή, *luster.*

The *Augite* of Werner (and volcanite *Delameth.*) included only the black mineral of igneous rocks—the *volcanic schorl* of earlier authors.

*Titaniferous augite.* Containing 0·5 to 4·5 p. c. titanium dioxide; cf. anals. 103 to 121.

**Alkali-augite.** Here belong varieties of augite characterized by the presence of alkalies, especially soda; cf. anals., 103 to 121; they hence approximate to acmite and ægirite. They are known chiefly from rocks rich in alkalies, as elæolite-syenite, phonolyte, leucityte, etc. A pyroxene intermediate between diopside and ægirite has been described by Brögger from the elæolite-syenite of southern Norway, which has $\mathfrak{c} \wedge \dot{c} = +52°$, Zs. Kr., **16**, 655, 1890. Cf. also Cross, Am. J. Sc., **39**, 359, 1890.

**Anal.**—The following are analyses, chiefly recent, of the typical varieties; for other analyses see 5th Ed., pp. 217 to 219; also Rg., Min. Ch., pp. 386–392, 1875, and Erg., 20–31, 1886, further Heddle, Trans. R. Soc. Edinburgh, **28**, 1878, and many papers on pyroxene in rocks in Jb. Min., and elsewhere.

[a] Incl. some MnO. [b] Incl. 0·27 MnO.

**Pyr., etc.**—Varying widely, owing to the wide variations in composition in the different varieties, and often by insensible gradations. Fusibility, 3·75 in diopside; 3·5 in salite, baikalite, and omphacite; 3 in jeffersonite and augite; 2·5 in hedenbergite. Varieties rich in iron afford a magnetic globule when fused on charcoal, and in general their fusibility varies with the amount of iron. Jeffersonite gives with soda on charcoal a reaction for zinc, and in O.F. on platinum wire for manganese; many others also give with the fluxes reactions for manganese. Most varieties are unacted upon by acids.

**Obs.**—Pyroxene is a common mineral in crystalline limestone and dolomite, in serpentine and in volcanic rocks; and occurs also, but less abundantly, in connection with granitic rocks and metamorphic schists; sometimes forms large beds or veins, especially in Archæan rocks. It occurs also in meteorites. The pyroxene of limestone is mostly white and light green or gray in color, falling under *diopside* (including malacolite, salite, coccolite); that of most other metamorphic rocks is sometimes white or colorless, but usually green of different shades, from pale green to greenish black, and occasionally black; that of serpentine is sometimes in fine crystals, but often of the foliated green kind called *diallage;* that of eruptive rocks is usually the black to greenish black *augite.*

In limestone the associations are often amphibole, scapolite, vesuvianite, garnet, orthoclase, titanite, apatite, phlogopite, and sometimes brown tourmaline, chlorite, talc, zircon, spinel, rutile, etc.; and in other metamorphic rocks mostly the same. In eruptive rocks it may be in distinct embedded crystals, or in grains without external crystalline form; it often occurs with similarly disseminated chrysolite (olivine), crystals of orthoclase, sanidine, labradorite, leucite, etc.; also with a rhombic pyroxene, amphibole, etc.

Pyroxene, as an essential rock-making mineral, is especially common in basic eruptive rocks. Thus, as augite, with a triclinic feldspar (usually labradorite), magnetite, often chrysolite, in basalt and basaltic lavas, diabase; in andesyte; also in trachyte; in peridotyte and pikryte; with nephelite in phonolyte. Further with elæolite, orthoclase, etc., in elæolite-syenite and augite-syenite, also as diallage in gabbro, in many peridotytes and the serpentines formed from them; as diopside (malacolite) in crystalline schists. In limburgyte, augityte, and pyroxenyte, pyroxene is present as the most prominent constituent, while feldspar is absent; it may also form rock masses alone nearly free from associated minerals.

Some of the more prominent foreign localities of pyroxene in its various forms are the following; many others have been noted in connection with the descriptions of varieties and analyses already given:

*Diopside* (alalite, mussite) occurs in fine crystals on the Mussa alp in the Ala valley in Piedmont, associated with garnets (hessonite) and talc in veins traversing serpentine; in fine crystals also at Traversella; at Zermatt in Switzerland; Schwarzenstein in the Zillerthal; Ober-Sulzbachthal and elsewhere in Tyrol and the Salzburg Alps; Reichenstein; Rezbanya, Hungary; Achmatovsk in the Ural with almandite, clinochlore; L. Baikal (*baikalite*) in eastern Siberia; Pargas, Orijärvi, and elsewhere in Finland. At Nordmark, Sweden, in fine crystals of varied type of form (cf. Flink, l. c.), but often with *a, b, c, p* prominent, and varying in composition from a diopside nearly free from iron to one containing iron in large amount, approximating to hedenbergite.

*Hedenbergite* was originally described from Tunaberg, Sweden; also from Arendal. Manganhedenbergite is from Vester Silfberg. *Schefferite* is from Långban, Wermland, Sweden, where it occurs embedded in calcite, also enclosing hematite and richterite; rhodonite and hedyphane occur in the neighborhood. Also from the Harstig mine at Pajsberg, with crystallized rhodonite (pajsbergite).

*Augite* (incl. fassaite) on the Pesmeda alp, Mt. Monzoni, and elsewhere in the Fassathal, as a contact formation; Traversella, Piedmont; the Laacher See and the Eifel; Sasbach in the Kaiserstuhl; Vesuvius, white rare, green, brown, yellow to black; Frascati; Etna; the Azores and Cape Verde Islands; the Sandwich Islands, as at the base of the cinder cones at the summit of Haleakala on Maui, where deposits of perfect crystals are found with chrysolite grains and glassy crystals of labradorite. Also in Japan, as on Bonin island (cf. Y. Kikuchi, J. Coll. Sc., Japan, 3, 67, 1889, for an account of some forms).

In N. America, occurs in *Maine*, at Raymond and Rumford, diopside, salite, etc.; at Deer Isle, diallage in serpentine. In *Vermont*, at Thetford, black augite, with chrysolite, in boulders of basalt. In *Mass.*, in Berkshire, white crystals abundant; at the Bolton quarries, same, good; Westfield and Blanford, diallage in serpentine. In *Conn.*, at Canaan, white cryst. 2–3 in. long by 1–2 in. broad, often externally changed by uralitization to tremolite, in dolomite; also the pyroxenic rock, called *canaanite;* in Trumbull, large green cryst. in limestone; in Reading, on the turnpike near the line of Danbury, small transp. cryst., and granular; at Watertown, near the Naugatuck, white diopside. In *N. York*, in N. Y. Co., white cryst. in dolomite; at Warwick, fine cryst.; in Westchester Co., white, at the Sing-Sing quarries; in Orange Co., in Monroe, at Two Ponds, cryst., often large, with scapolite, titanite, etc., in limestone; 3 m. S.E. of Greenwood furnace, salite with coccolite; ½ m. E. of same, in cryst. with mica in limestone; 1 m. W. of Coffee's Hotel in Monroe, black coccolite; 2½ m. N. of Edenville, gray cryst.; 1 m. N.W. of Edenville, black cryst. in limestone; in Cornwall, the var. *hudsonite;* near Amity and Fort Montgomery, good; in Forest-of-Dean, lamellar, green, and bronze-colored, with black coccolite; in Putnam Co., near Patterson, grayish white cryst., abundant; at Rogers' Rock, L. George, massive and granular (coccolite), gray, green, brown; near Oxbow, on Vrooman Lake; in Lewis Co., at Diana, white and black cryst.; in St. Lawrence Co., at Fine, in large cryst.; at De Kalb, fine diopside; also at Gouverneur, Rossie, Russell, Pitcairn; in Essex Co., near Long Pond, cryst., also beautiful green coccolite; at Willsboro', green coccolite with titanite and wollastonite; at Moriah, coccolite, in limestone mostly changed to serpentine forming a useful marble.

In *N. Jersey*, Franklin Furnace, Sussex Co., good cryst., also *jeffersonite*. In *Penn.*, near Attleboro', cryst. and granular; in Pennsbury, at Burnett's quarry, diopside; at the French Creek mines, Chester Co., chiefly altered to fibrous amphibole; at Bailey's quarry, East Marlborough. In *Maryland*, Harford Co., at Cooptown, diallage. In *Delaware*, at Wilmington, a hypersthene-like variety, Nuttal's *Maclureite*. In *Tennessee*, at the Ducktown mines.

In *Canada*, at Calumet I., grayish green cryst. in limestone with phlogopite; at the High Falls of the Madawaska, large crystals, having cryst. of hornblende attached; in Kildau as a rock; in Bathurst, colorless or white cryst.; near Ottawa, in large subtrp. cryst., in limestone; at Grenville, dark green cryst., and granular; at Montreal, Rougemont and Montarvelli Mts., black in doleryte; Burgess, Lanark Co.; Renfrew Co., with apatite, titanite, etc.; Orford, Sherbrooke Co., white crystals, also of a chrome-green color with chrome garnet; at Hull and Wakefield, white crystals with nearly colorless garnets, honey-yellow vesuvianite, etc. At many other points in the Archæan of Quebec and Ontario, especially in connection with the apatite deposits.

**Alt.**—Pyroxene undergoes alteration in different ways. A change of molecular constitution without essential change of composition, i.e., by *paramorphism* (using the word rather broadly), may result in the formation of some variety of amphibole. Thus, the white pyroxene crystals of Canaan, Conn., are often changed on the exterior to tremolite; similarly with other varieties at many localities. See URALITE, p. 390.

Further there may be alteration with chemical change in many ways, as has been explained by Bischof, and many species have been instituted on the material in different stages of change. In the simplest, there is only a taking up of water, producing a "hydrous augite." The water often found in analyses may be from this source. In many cases a loss of silica appears to attend this hydration; and often, also, a loss of one or more of the bases (of which the lime and iron are the first to go), through the dissolving agency of waters holding carbon dioxide, or carbonates, in solution. A complete removal of the lime and iron produces *steatite* or *talc*, a common material of pseudomorphs. *Rensselaerite* is a variety of steatite, having sometimes the cleavage of pyroxene. Pyrallolite is also in part talc or steatite. *Saponite* and *serpentine* are other results of the same kind of alteration, the latter, especially, very common. *Hortonite* is a steatitic pseudomorph of pyroxene, found in Orange Co., N. Y., with chondrodite. See further under TALC, SERPENTINE. *Epidote* is another mineral resulting from the change involving oxidation of the iron. In the case of the aluminous pyroxene, when all the bases except the alumina are removed and water taken up, there may result *cimolite*, a whitish claylike earth, which has been observed constituting pseudomorphs of augite at Bilin in Bohemia. Under the action of alkaline waters, alkalies may be introduced. Thus the hydrous mineral *glauconite* or *green earth* may result as a constituent of some augite pseudomorphs; or *mica*, which has been observed by Kjerulf as a pseudomorph after augite, in the Eifel.

Some of the substances formed by alteration are further mentioned below.

**Artif.**—Diopside has been observed as a furnace product at the iron-works of Philipsburg, N. Jersey (G. J. Brush. Am. J. Sc., **39**, 132, 1865); and dark-colored pyroxene at Gaspenberg; in an old furnace near Hackenburg; a copper furnace near Dillenburg; at Falun and Oldbury; a manganese-augite at Mägdesprung. Augite in small yellow crystals has been found in old fumaroles at Eiterkopfe, near Andernach (Rath).

Formed in crystals, as diopside, artificially by the action of silicon chloride on magnesia (Daubrée); also, a grayish-white var., by mixing the constituents and exposing to a high heat (Berthier); also, a variety of compounds (Lechartier) by fusing the constituents at a bright red heat with an excess of calcium chloride in a carbon crucible enveloped in one of earthenware. See further, Fouqué & Lévy, Synth. Min., 102–110, 1882. Synthetic experiments have been also made by Doelter, Jb. Min., **2**, 51, 1884; also on the results of fusion, as in reforming pyroxene from the fused mass, by Becker, Zs. G. Ges., **37**, 10, 1885. See also Vogt, Ak. H. Stockh., Bihang, **9**, No. 1., 1884; Arch. Math. Nat., Christ., **30**, 34, *et seq.*, 1889, who describes various pyroxenic minerals formed from fusion in slags, etc., including augite, a monoclinic (or triclinic) $MgSiO_3$, a similarly crystallized $FeSiO_3$, also enstatite, rhodonite, an hexagonal $CaSiO_3$, etc.

**Ref.**—[1] Vesuvian augite, yellow variety, G. = 3·277, anal. 67, l. c. It is noteworthy that the angles vary but little even for a wide variation in composition. For a discussion of the change in form with varying amount of FeO and $(Al,Fe)_2O_3$, see Rath, Pogg., **6**, 345, 1873; Flink, Zs. Kr., **11**, 486, 1886. The following will serve for comparison, the axes being accepted as calculated by Kk., Rath, La Valle, Flink, etc., cf. anals. preceding and ref. below:

| | | $\grave{a}$ : $\bar{b}$ : $\acute{c}$ | $\beta$ |
|---|---|---|---|
| Russian and other pyroxenes, mean value (Kk.) | | 1·09312 : 1 : 0·58946 | 74° 11½′ |
| *Diopside*, Val d'Ala | (cf. anal. 1, 2) | 1·09126 : 1 : 0·58949 | 74° 8⅚′ |
| " Nordmark | ( " 10) | 1·09197 : 1 : 0·58694 | 74° 12⅔′ |
| " " | ( " 11) | 1·09220 : 1 : 0·58689 | 74° 13′ |
| " " | ( " 12) | 1·09186 : 1 : 0·58659 | 74° 16′ |
| " " | ( " 13) | 1·09175 : 1 : 0·58562 | 74° 19¾′ |
| " " | ( " 14,15) | 1·09123 : 1 : 0·58429 | 74° 34¾′ |

| " " *yellow* | ( " 67) | 1·09213 : 1 : 0·58931 | 74° 10⅙′ |

Since in pyroxene the angle *ac* differs but little from the angle *a'p*, it is possible so to select the axes as to make the angle of obliquity, $\beta$, nearly 90°. This method, proposed by Rath and later by Tschermak, and adopted by Groth (Tab. Ueb., p. 130, 1889) has a certain advantage in that it exhibits clearly the morphological similarity between the orthorhombic and monoclinic pyroxenes. It is not to be recommended otherwise, however, since the resulting symbols of the commonly occurring planes are often highly complex; moreover, it is clear that the basal plane in the position of Naumann here, as ordinarily, adopted is naturally a *fundamental* plane since it is parallel to it that the common twinning lamellæ occur, with the resulting easy parting so often observed. Cf. also Flink, Zs. Kr., **16**, 299, 1890, who notes another objection.

[2] Cf. Kk., Min. Russl., **4**, 258, 1862; Mlr., Min., p. 290, 1852; Dx. Min., **1**, 55 1862; Hbg., Min. Not., **1**, 18, 1856, **5**, 21, 1863; Rath, Pogg., Erg., **6**, 338, 1873, Ber. nied. Ges. (311), July 7, 1886. A list of planes with authorities is given by Götz, Zs. Kr., **11**, 242, 1885; another by La Valle, Mem. Acc. Linc., **3**, 226, 1886; also a critical summary with literature by Gdt., Index, **2**, 523, 1890.

The following are more or less well-defined alteration products of various kinds of pyroxene; see further for analyses, etc., 5th Ed., pp. 220–223.

HECTORITE *S. Herbert Cox*, Trans. N. Z. Inst., **15**, 409, 1882. A hydrated pyroxenic mineral from the serpentine rocks of the Dun Mts., New Zealand. Occurs in radiating groups of thin flexible laminæ. H. = 2–2·5. Color whitish green to dark green. Analysis by W. Skey:

$SiO_2$ 57·89 $Al_2O_3$ 4·74 FeO 18·46 MgO 13·94 CaO 1·99 $H_2O$ 2·98 $Fe_2O_3$,MnO *tr.* = 100

HYDROUS DIALLAGE. Various forms have been described, 5th Ed., p. 221.

MONRADITE *Erdmann*, Ak. H. Stockh., 103, 1842. Probably a slightly altered pyroxene. Described as occurring granular massive, with two unequal cleavages mutually inclined about 50°; with H. = 6, G. = 3·267; color yellowish, honey-yellow, and luster vitreous. From Bergen in Norway. Named after Dr. Monrad.

PICROPHYLL *Svanberg*, Pogg., **50**, 662, 1839. From Sala, where it occurs both massive, with the cleavage of pyroxene, and fibrous, of a greenish gray color, with H. = 2·5 and G. = 2·75. Named from πικρός, *bitter*, and φύλλον, *leaf*, in allusion to the odor when moistened.

PITKÄRANTITE *Scheerer*, Pogg., **93**, 100, 1854. Pikärandite. Has a leek-green or dark green color, and looks like unaltered pyroxene. From Pitkäranta in Finland. Scheerer refers here part of pyrallolite.

PYRALLOLITE *N. Nordenskiöld*, Schw. J., **31**, 389, 1820. From Finland, where it occurs mostly in limestone, with pyroxene and scapolite. A pyrallolite from Sibbo in Finland has been named *Vargasite*, after Count Vargas, Huot Min., **2**, 676, 1841; Wargasit *Germ.* The crystalline structure is that of pyroxene. Named from πῦρ, *fire*, αλλος, *other*.

STRAKONITZITE *Zepharovich*, Jb. G. Reichs., **4**, 695, 1853. Approaches steatite. It occurs in greenish yellow crystals, soft and greasy in feel, with G. = 1·91.

URALITE *Rose*, Pogg., **22**, 321, 329, 1831; **27**, 97, 1833; **31**, 609, 1834. Pyroxene altered to amphibole. See further, p. 390.

**326. ACMITE.** Achmit *Ström*, Ak. H. Stockh., 160, 1821, and *Berz*,, ib., 163. Akmit *Germ.* Acmite.

AEGIRITE. Ægirin *Esmark*, Berzelius, Jb. Min., 184, 1835.

Monoclinic. Axes: $\grave{a} : \bar{b} : \acute{c} = 1·09957 : 1 : 0·60120$; $\beta = 73° 10\frac{5}{6}' = 001 \wedge 100$ Brögger[1].

$100 \wedge 110 = {}^*46° 28'$, $001 \wedge \bar{1}01 = 31° 52\frac{1}{6}'$, $001 \wedge 011 = 29° 55\frac{1}{6}'$.

**Forms**[1]: *f* (310, $i$-$\bar{3}$) *H* ($\bar{3}02$, $\frac{3}{2}$-$\bar{i}$) *O* ($\bar{6}61$, 6) *S* ($\bar{3}11$, 3-$\bar{3}$)
*a* (100, $i$-$\bar{i}$) *L* (730, $i$-$\frac{7}{3}$) *s* ($\bar{1}11$, 1) *Ω* ($\bar{8}81$, 8) *Q* ($\bar{1}61$, 6-$\grave{6}$)
*b* (010, $i$-$\grave{i}$) *m* (110, *I*) *λ* ($\bar{3}31$, 3) *P* (261, − 6-$\grave{3}$) *K* ($\bar{1}91$, 9-9)
*χ* (510, *i* 5) *p* ($\bar{1}01$, 1-$\bar{i}$)

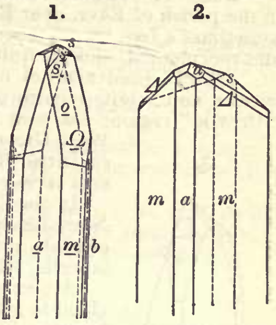
*ff'''* = 38° 40′ *a'H* = 60° 59½′ *a's* = 77° 1′ *ss'* = 60° 17′
*mm'''* = *92° 56′ *m's* = 58° 45½′ *a'S* = *39° 35′ *OO'* = 95° 25½′
*a'p* = 74° 57′ *m'O* = 12° 6½′ *a'O* = 50° 8½′ *SS'* = *38° 20′

On ÆGIRITE: Brögger has observed:

*a, b, c, V* (11·1·0, $i$-$\bar{1}\bar{1}$), *χ, f, W* (16·15·0, $i$-$\bar{\tfrac{16}{15}}$), *m, p, u* (111, − 1), *v* (221, − 2), *s, π* ($\bar{5}51$, 5), *O, Ω, Λ* (451, − 5-$\frac{5}{4}$), *Δ* (592, − $\frac{9}{2}$-$\frac{9}{5}$), *Z* ($\bar{4}$·10·3, $\frac{10}{3}$-$\frac{5}{2}$), *k* ($\bar{3}12$, $\frac{3}{2}$-$\bar{3}$).

The angles are sensibly the same as those of acmite; Brögger measured:

*mm'''* = 92° 49′, *a'p* = 74° 56′, *ss'* = 60° 15′, *uu'* = 48° 41′, *aΔ* = 58° 42′, *mΔ* = 19° 52′, also *ΔΔ'* = 107° 0½′ (calc., Bgr.), *Δ* is a characteristic form.



1, *Acmite;* 2, *Ægirite,* Norway, Brögger.

Twins: tw. pl. *a*, very common, f. 1; crystals often polysynthetic, with enclosed twinning lamellæ. Crystals long prismatic, vertically striated or channeled; the prisms bent, twisted or broken. Acute terminations very characteristic; faces often rough or rounded (*a*, *b*, *p*, *s*). Inclined hemihedrism, like pyroxene, probable.

The above applies to ordinary *acmite*.

For *ægirite*, the crystals are prismatic ‖ $\dot{c}$ with *m* prominent, also *a*, *b*, and usually terminated by *s* ($\bar{1}11$), or *p* ($\bar{1}01$), or with *Δ* (592) and *p* ($\bar{1}01$); again, prismatic by extension of ($\bar{1}11$) with *m* small. Twins not common. Also occurs in groups or tufts of slender acicular to capillary crystals, and in fibrous forms.

Cleavage: *m* distinct; *b* less so. Fracture uneven. Brittle. H. = 6–6·5. G. = 3·50–3·55 Bgr. Luster vitreous, inclining to resinous. Streak pale yellowish gray. Color brownish or reddish brown, green; in the fracture blackish green. Subtransparent to opaque.

Crystals of acmite often show a marked zonal structure, green within and brown on the exterior, particularly ‖ *a*, *b*, *p* ($\bar{1}01$), *s* ($\bar{1}11$). The brown portion (acmite, see below) is feebly pleochroic, the green (ægirite) strongly pleochroic. Both have absorption $\mathfrak{a} > \mathfrak{b} > \mathfrak{c}$, but the former has $\mathfrak{a}$ light brown with tinge of green, $\mathfrak{b}$ greenish yellow with tinge of brown, $\mathfrak{c}$ brownish yellow; the latter has $\mathfrak{a}$ deep grass-green, $\mathfrak{b}$ lighter grass-green, $\mathfrak{c}$ yellowish brown to yellowish.

Optically —. Ax. pl. ‖ *b*. $Bx_a \wedge \dot{c} = \mathfrak{a} \wedge \dot{c} = +2\frac{1}{2}°$ to 6°; for acmite $+5\frac{1}{2}°$ to 6°, for ægirite $+2\frac{1}{2}°$ to $3\frac{1}{2}°$. Axial angles large. For ægirite, Bgr.:

Na $2E = 134° 27'$ $2H_a = 63° 41'$ $2H_o = 117° 18'$. ∴ $2V_a = 63° 28'$ $\beta = 1·753$

Also, Låven, $\beta_y = 1·8084$ Na, Sanger (Rosenbusch).

**Comp., Var.**—Essentially $Na\overset{III}{Fe}(SiO_3)_2$ or $Na_2O.Fe_2O_3.4SiO_2$ = Silica 52·0, iron sesquioxide 34·6, soda 13·4 = 100. Ferrous iron is also present.

The analysis of Doelter as interpreted by him gives, with 89 p. c. of the characteristic $Na\overset{III}{Fe}(SiO_3)_2$, also 6 p. c. of $\overset{II}{Fe}\overset{III}{Fe_2}SiO_6$, 3·7 p. c. of $\overset{II}{Fe}AlSiO_6$ and 1·3 p. c. of $CaMn(SiO_3)_2$. Brögger, however, is inclined to assume the presence, with 85 p. c. of $Na_2Fe_2(SiO_3)_4$, of 15 p. c. of $FeFe_2(SiO_3)_4$.

The essential identity of acmite and ægirite was shown by Tschermak, Min. Mitth., 33, 1871; it had been earlier suggested by Rose. Kryst. Ch., 76, 1852.

Brögger regards the interior green, highly pleochroic, portion of the acmite crystals (noted above) as identical with the characteristic ægirite, while to the acmite proper belongs the feebly pleochroic brown exterior with greater angle of extinction (to + 6°). *Acmite* is characterized by the prevalence of twins, the acute terminations, the common occurrence of *S* ($\bar{3}11$), etc. With *ægirite* simple crystals are the rule and twins rare; the crystals are more often bluntly terminated, with *Δ* (592) prominent; also of quite distinct habit, prismatic ‖ $\bar{1}11$. The color and higher angle of extinction of the acmite indicates greater iron percentage.

**Anal.**—1, Rg., Pogg., **103**, 300, 1858. 2, Doelter, Min. Mitth., **1**, 379, 1878. 3, Id., ib., p. 374. 4, 5, Id., ib., Zs. Kr., **4**, 34, 1879. That these analyses are of ægirite and not arfvedsonite seems to be sufficiently shown by Rg., Min. Ch., Erg., 24, 1886, cf. Lorenzen. 6, Lorenzen, Min. Mag., **5**, 55, 1882. 7, Forsberg, quoted by Ramsay, Fennia, **3**, No 7, 1890 (Geol. Beob. Halbinsel Kola.) 8, J. L. Smith, Am. J. Sc., **10**, 60, 1875.

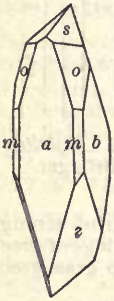
**Pyr., etc.**—B.B. fuses at 2 to a lustrous black magnetic globule, coloring the flame deep yellow; with the fluxes reacts for iron and sometimes manganese. Slightly acted upon by acids.

**Obs.**—The original *acmite* occurs at Rundemyr, east of the little lake called Rökebergskjern, in the parish of Eker, near Kongsberg, Norway, in a pegmatyte vein; it is in slender crystals, sometimes a foot long, embedded in feldspar and quartz; the crystals are often bent or fractured and recemented, and are quite fragile.

*Ægirite* (and acmite) occurs with leucophanite, cancrinite, elæolite, etc., in the elæolite-syenite and augite-syenite of southern Norway, especially along the Langesund fiord in the "Brevik" region; also near Laurvik, Sande fiord, and Fredriksvärn. Also at Kangerdluarsuk, West Greenland, in a sodalite-syenite with eudialyte, arfvedsonite, etc.; also at Ditró, Transylvania (acmite?), and similarly associated elsewhere; in the acid lavas of San Miguel, one of the Azores.

3.



Schrauf.

In the U. S., in minute crystals in a dike of elæolite-syenite in northwestern New Jersey. At the Hot Springs, Magnet Cove, Arkansas, in fine prismatic crystals, up to 8 inches or more in length, often bent and twisted and with tapering terminations. In Canada, at Montreal and Belœil in elæolite-syenite.

A green pyroxene occurring as an alteration product of a blue amphibole allied to arfvedsonite or riebeckite (see p 400, is referred to ægirite by Cross; it occurs in certain rocks forming dikes in Archæan gneisses in Custer Co., Colorado. Am. J. Sc., **39**, 359, 1890.

Brögger (l.c., p. 330) is inclined to regard the crocidolite of Stavern, Norway, and perhaps also that of S. Africa as a variety of ægirite (*ægirin-asbest*); but see crocidolite, p. 400)

*Acmite* is from *ἀκμή, a point*, in allusion to the pointed extremities of the crystals. *Ægirite* is from Ægir, the Icelandic god of the sea.

**Alt.**—Occurs altered to analcite in Norway (Bgr.). Williams suggests that manganpectolite at Magnet Cove may have been derived from the ægirite.

**Ref.**—[1] Zs. Kr., **16**, 295, 1890; he describes in detail the acmite and ægirite of the islands in the Langesund fiord, Norway, gives the earlier literature for the species, etc. For early observations, see Mitscherlich, Ed. Phil. J., **9**, 55, 1823; Ph., Min., 151, 1837; Rath, Pogg., **111**, 254, 1860; Schrauf, Atlas, Tf. II, 1864.

Note also that the *s* ($\bar{1}11$) of Brögger is *s* (011, T) of Rath, *p* = *c* (001), *S* ($\bar{3}11$) = (211, m), *O* ($\bar{6}61$) = *o* (561), *P* (261) = *z* ($\bar{3}61$); cf. f. 3. This change of position, which better exhibits the relation of form to pyroxene, is probably the reason why most authors have given $Bx_a \wedge \dot{c} = -3°$, while Brögger makes the same angle positive, that is with him the bisectrix ($\mathfrak{a}$) falls in the front obtuse axial angle, instead of in the acute angle.

**327. SPODUMENE.** *D'Andrada*, Scherer's J., **4**, 30, 1800; J. Phys., **51**, 240, 1800. Triphane *Haüy*, Tr., **4**, 1801. Hiddenite *J. L. Smith*, Am. J. Sc., **21**, 128, 1881.

Monoclinic. Axes: $\breve{a} : \bar{b} : \dot{c} = 1{\cdot}1238 : 1 : 0{\cdot}6355$; $\beta = {}^*69° \, 40' = 001 \wedge 100$ J. D. Dana[1].

$100 \wedge 110 = 46° \, 30'$, $001 \wedge \bar{1}01 = 33° \, 25\frac{1}{4}'$, $001 \wedge 011 = 30° \, 47\frac{1}{2}'$.

**Var.**—1. *Ordinary.* Color white or nearly white, yellowish, rarely amethystine; commonly in flattened prismatic crystals, often very large, up to 4 feet or more in length and 12 inches across.

2. *Hiddenite.* Color yellow-green to emerald-green, the latter used as a gem, resembling the emerald but showing more variety of color because of its pleochroism. In small (½ in. to 2 inches long) slender prismatic crystals, surfaces often etched as the result of the action of some natural solvent.

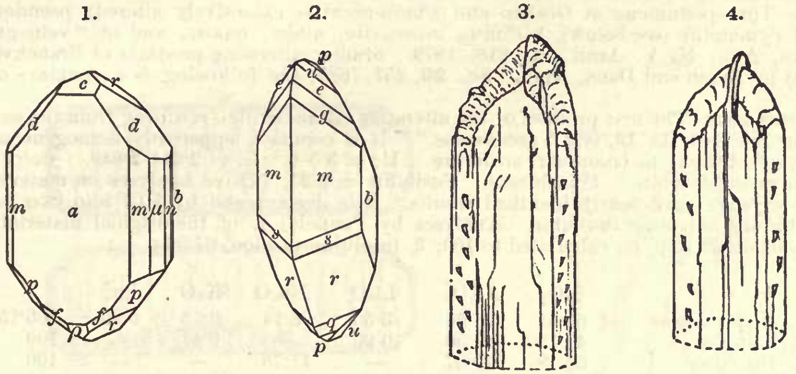

Fig. 1, Norwich, Mass. 2–4, *Hiddenite*, Alexander Co., N. C. 3, 4, Sketches of natural crystals, W. E. Hidden.

**Comp.**—$LiAl(SiO_3)_2$ or $Li_2O.Al_2O_3.4SiO_2$ = Silica 64·5, alumina 27·4, lithia 8·4 = 100. Generally contains a little sodium; the variety hiddenite also chromium, to which the color may be due.

[a] Incl. MnO 0·12. [b] $Fe_2O_3$.

The formula, as given above, was first correctly established by Doelter.

**Pyr., etc.**—B.B. becomes white and opaque. swells up, imparts a purple-red color (lithia) to the flame, and fuses at 3·5 to a clear or white glass. The powdered mineral, fused with a mixture of potassium bisulphate and fluorite on platinum wire, gives a more intense lithia reaction. Not acted upon by acids.

**Obs.**—Occurs on the island of Utö in Södermanland, Sweden, with magnetite, quartz, tourmaline, and feldspar; also near Sterzing and Lisens in Tyrol; of a pale green or yellowish color, embedded in granite, at Killiney Bay, near Dublin, and at Peterhead in Scotland; in small transparent crystals of a pale yellow in Brazil, province of Minas Geraës.

In the U. S., in granite at Goshen, Mass., associated at one locality with blue tourmaline and beryl; also at Chesterfield, Chester, Huntington (formerly Norwich), and Sterling, Mass.; at Windham, Maine, with garnet and staurolite; at Peru, with beryl, triphylite, petalite; at Winchester, N. H.; at Brookfield, Ct., a few rods north of Tomlinson's tavern, in small grayish or greenish white individuals looking like feldspar; at Branchville, Ct., in a vein of pegmatyte, with lithiophilite, uraninite, several manganesian phosphates, etc.; the crystals are often of immense size embedded in quartz; near Stony Point, Alexander Co., N. C., the variety *hiddenite* in cavities in a gneissoid rock with beryl (emerald), monazite, rutile, allanite, quartz, mica, etc.; near Ballground, Cherokee Co., Ga.; in South Dakota at the Etta tin mine in Pennington Co., in immense crystals. At Huntington, Mass., it is associated with triphylite, mica, beryl, and albite; one crystal from this locality was 16½ inches long, and 10 inches in girt.

The name spodumene is from σποδιός, *ash-colored.* Named triphane by Haüy from τριφανής, *appearing threefold,* in allusion to his idea that the crystals are divided by three planes with nearly equal ease. *Hiddenite* is named for W. E. Hidden of New York.

**Alt.**—The spodumene at Goshen and Chesterfield is extensively altered; pseudomorphs occur of cymatolite (see below), killinite, muscovite, albite, quartz, and of "vein granite;" cf. Julien, Ann. N. Y. Acad., **1**, 318, 1879. Similar alteration-products at Branchville are described by Brush and Dana, Am. J. Sc., **20**, 257, 1880; the following is a summary of their results:

*β Spodumene.* The first product of the alteration (Branchville), resulting from the exchange of Na for one-half the Li, is "*β spodumene.*" It is compact, apparently homogeneous, with an indistinct fibrous to columnar structure. H. = 5·5–6. G. = 2·644–2·649. Color white, milky, or greenish white. Translucent. Fusibility = 2·25. Three analyses on material from different crystals gave nearly identical results. It is decomposed by HCl into two portions, one soluble and the other insoluble. Analyses by Penfield: 1, of the original material; 2, the soluble portion 32·10 p. c., calculated to 100; 3, insoluble portion, 67·56 p. c.:

| | | $SiO_2$ | $Al_2O_3$ | $Li_2O$ | $Na_2O$ | $K_2O$ | ign. | |
|---|---|---|---|---|---|---|---|---|
| 1. *β spodumene* | $\frac{2}{2}$ | 61·51 | 26·56 | 3·50 | 8·14 | 0·15 | 0·29 | = 100·15 |
| 2. Soluble | | 48·13 | 40·50 | 10·90 | — | 0·47 | — | = 100 |
| 3. Insoluble | | 68·18 | 20·07 | — | 11·75 | — | — | = 100 |

The insoluble portion is albite, the soluble is eucryptite. Examined under the microscope in sections (1) parallel to fibers, the irregular interlacing fibers of eucryptite are seen embedded in albite; (2) transverse to fibers, the eucryptite is in bands with hexagonal outline, surrounded by albite, like quartz in a "graphic granite." See further *Eucryptite,* p. 426.

*Cymatolite.* A second stage in the alteration is the formation of cymatolite (C. U. Shepard, Dana, Min., p. 455, 1868). It has a fibrous to wavy structure, silky luster, white or slightly pinkish color; H. = 1·5–2; G. = 2·69–2·70. The cymatolite from Goshen was earlier (Eng. Mng. J., **22**, 217) called *aglaite* by Julien. Analyses.—1, 2, 3, Julien, l. c. 4, Penfield, l. c.

| | | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | MnO | MgO | CaO | $Li_2O$ | $Na_2O$ | $K_2O$ | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|

| 2. *Aglaite* | | 58·11 | 24·38 | 1·66 | 0·18 | 0·75 | 0·48 | 0·09 | 2·57 | 8·38 | 3·01[b] | = 99·61 |
| 3. Chesterfield | $\frac{2}{2}$ | 58·58 | 22·28 | 1·77 | 0·15 | 0·45 | 0·93 | 0·10 | 9·08 | 4·48 | 2·08[c] | = 99·90 |
| 4. Branchville | $\frac{2}{2}$ | 60·55 | 26·38 | — | 0·07 | — | — | 0·17 | 8·12 | 3·34 | 1·65 | = 100·28 |

[a] With nitrogenous organic matter 0·44 [b] Do. 0·43. [c] Do. undet.

This corresponds to: $(Na,K,H)AlSi_2O_6$ or $(K,H)AlSiO_4 + NaAlSi_3O_8$. The microscopic examination shows that cymatolite is not, as previously assumed, a simple mineral, but, corresponding to the formula, a very uniform mechanical mixture of *muscovite* and *albite.* In some sections the transitions from β spodumene to cymatolite, i.e. from eucryptite to muscovite, are clearly seen. In other cases the muscovite and albite have each segregated together, so that they are distinct. For example, in figure 2, *s* = unaltered spodumene, *β* = *β* spodumene, *c* = cymatolite, *g* = mica, *a* = albite. Furthermore the successive stages of alteration may be seen in the same crystal, thus as shown in fig. 1, 1*a*, 1*b*, 1*c*, three sections at intervals of 3 to 6 inches in a large crystal 15 inches in length; *s*, *β*, *c* having the same meaning as in fig. 2.

As further steps in the alteration there result: albite, often fibrous, like *β* spodumene; also muscovite, and granular microcline.

*Killinite.* Structure, if any, that of the original spodumene. Compact, crypto-crystalline. H. = 3·5; G. = 2·623–2·652. Luster dull and greasy to vitreous. Color bluish green, greenish gray to olive-green, oil-green, and greenish black. Analyses.—1, Julien. 2, Penfield, prismatic variety, l. c. 3, Dewey, compact, ibid.

| | $SiO_2$ | $Al_2O_3$ | $Fe_2O_3$ | FeO | MnO | CaO | $K_2O$ | $Na_2O$ | $Li_2O$ | $H_2O$ | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| 1. Chesterfield | 46·80 | 32·52 | — | 2·33 | 0·04 | 0·77 | 7·24 | 0·78 | 0·32 | 7·66 | MgO 0·48, CoO 0·04, organic 1·14 = 100·12 |
| 2. Branchville | 48·93 | 34·72 | 0·54 | 0·33 | 0·64 | — | 9·64 | 0·35 | — | 5·04 | = 100·19 |
| 3. " | 53·47 | 32·36 | 0·79 | 0·42 | 0·72 | 0·17 | 7·68 | 0·44 | 0·04 | 4·07 | = 100·16 |

The original killinite (Thomson, Min., **1**, 330, 1836) was from Killiney Bay, Ireland, where it is also an alteration-product of spodumene, see further 5th Ed., p. 480.

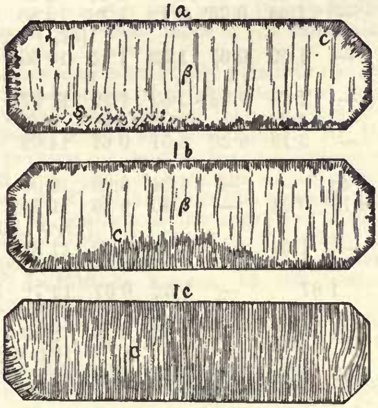
The following scheme explains the above changes of the spodumene, supposing an exchange of the alkali metal:

$$\text{Spodumene } 2[\mathrm{LiAlSi_2O_6}] = [\underset{\text{Eucryptite}}{\mathrm{LiAlSiO_4}} + \underset{\text{Albite}}{\mathrm{NaAlSi_3O_8}}]\ \beta \text{ spodumene}$$

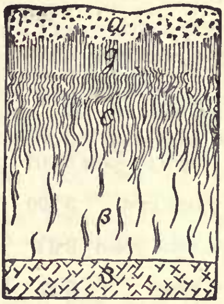
$$= [\underset{\text{Muscovite}}{\mathrm{(K,H)AlSiO_4}} + \underset{\text{Albite}}{\mathrm{NaAlSi_3O_8}}] \text{ cymatolite}$$

$$= \underset{\substack{\text{Muscovite}\\ \text{(or killinite)}}}{\mathrm{(K,H)AlSiO_4}} + \begin{cases} \mathrm{NaAlSi_3O_8} \text{ albite} \\ \text{or } \mathrm{KAlSi_3O_8} \text{ microcline} \end{cases}$$

1.



2.



Experiments showing the effect upon spodumene of solutions of potassium and sodium carbonates, see Lemberg, Zs. G. Ges., **39**, 584, 1887.

**Ref.**—[1] Min., p. 693, 1850, 169, 1852; Rath obtained for Alexander Co., No. Carolina, spodumene, $\breve{a} : \bar{b} : \dot{c} = 1·1283 : 1 : 0·62345$; $\beta = 69° 32\frac{1}{2}'$; the crystals were measured with the help of attached glass plates, Ber. nied. Ges., May 3, 1886. The surface of the crystals of hiddenite are often extensively etched, and some of the planes noted, cf. [3] and [4] below, may be simply corrosion forms. [2] J. D. D., l. c. [3] E. S. D., Alex. Co., Am. J. Sc., **22**, 179, 1881. [4] Rath, l. c. [5] Am. J. Sc., **32**, 204, 1886. [6] Greim, Jb. Min., **1**, 253, 1889. [7] Min. Roches, 266, 1888.

**328. JADEITE.** Nephrite or Jade pt. Jadeite *Damour*, C. R., **56**, 861, 1863. Chloromelanite *Id.*, ibid., **61**, 313, 357, 1865.

Monoclinic (or triclinic)[1], with cleavage and optical characters like pyroxene. Only known massive, with crystalline structure, sometimes granular, also obscurely columnar, fibrous foliated to closely compact.

Cleavage: prismatic, at angles of about 93° and 87°; also orthodiagonal, difficult. Fracture splintery. Extremely tough. H. = 6·5–7. G. = 3·33–3·35. Luster subvitreous, pearly on surfaces of cleavage. Color apple-green to nearly emerald-green, bluish green, leek-green, greenish white, and nearly white; sometimes white with spots of bright green. Optically biaxial, negative. $Bx_a \wedge \dot{c} = 30°$ to 40°, $2H_{a.y} = 82° 48'$ Knr. Streak uncolored. Translucent to subtranslucent.

**Comp.**—Essentially a metasilicate of sodium and aluminium corresponding to spodumene, $NaAl(SiO_3)_2$, or $Na_2O.Al_2O_3.4SiO_2$ = Silica 59·4, alumina 25·2, soda 15·4 = 100

*Chloromelanite* is a dark green to nearly black kind of jadeite, containing iron sesquioxide and not conforming exactly to the above formula. Named from χλωρός, *green*, and μέλας, *black*.

[a] $Cr_2O_3$.

**Pyr., etc.**—B.B. fuses readily to a transparent blebby glass. Not attacked by acids after fusion, and thus differing from saussurite.

See Lemberg on the results of treatment of jadeite with alkaline carbonates; it is shown that, after fusion, jadeite behaves like fused analcite. Zs. G. Ges., **39**, 586 *et seq.*, 1887.

**Obs.**—Occurs chiefly in Eastern Asia, thus in the Mogoung distr. in Upper Burma, in a valley 25 miles southwest of Meinkhoom; this jadeite is found in rolled masses in a reddish clay, and specimens gave a specific gravity of 3·34, 3·33, 3·24; easily fusible (Mallet[2]). Also in Yungchang, province of Yunnan, southern China (Pumpelly[3]); in Thibet. Much uncertainty prevails, however, as to the exact localities, since jadeite and nephrite have usually been confounded together. May occur also on the American continent, in Mexico and South America; perhaps also in Europe.

Analyses 29, 30 are of rolled masses of jadeite from the shores of L. Neuenburg in Switzerland, which may have come from a local source. Anal. 36–40 are of various soda-bearing rocks, approaching jadeite more or less closely in composition, and also believed to have been of European origin.

Jadeite has long been highly prized in the East, especially in China, where it is worked into ornaments and utensils of great variety and beauty. It is also found with the relics of early man, thus in the remains of the lake dwellers of Switzerland, at various points in France, in Mexico. Greece, Egypt, and Asia Minor. Mr. Pumpelly remarks that the *feitsui* (= kingfisher plumes) is perhaps the most prized of all stones among the Chinese. He also observes that the *chalchihuitl* of the ancient Mexicans, of which he had seen many specimens, is probably the same mineral; but W. P. Blake refers this name to the turquois from the vicinity of Santa Fé. See turquois. The question of the origin and distribution of jadeite is of great interest and has been much discussed. Cf. Fischer, "Nephrit und Jadeit nach ihren mineralogischen Eigenschaften, so wie nach ihrer urgeschichtlichen und ethnographischen Bedeutung," Stuttgart, 1875, 1880. Also Arzruni, Zs. Ethnol., **15**, 163. 1883; Meyer, Mitth. Anthropol. Ges., Wien, **15**, 1885; *et al.*, see further jade, below.

**Ref.**—[1] On the microscopic structure of jadeite, cf. Dx., l. c., 1881; Cohen, l. c.; Krenner, Jb. Min., **2**, 173. 1883; Arzruni, Jb. Min., **2**, 6 ref., 1885; Merrill, Proc. U. S. Mus., **11**, 123, 1888. [2] Min. India, 94, 1887.

[3] Pumpelly, Geol. China, 1866 (Smithson. Contrib., **15**, 118).

JADE. A general term used to include various mineral substances of tough compact texture and nearly white to dark green color used by early man for utensils and ornaments, and still highly valued in the East, especially in China, where it is called *Yu* or *Yu-shih* (yu-stone). It includes properly two species only: *nephrite*, a variety of amphibole (p. 389), either tremolite or actinolite, with G. = 2·95–3·0, and *jadeite*, which is classed with the pyroxene group and in composition is a soda-spodumene, with G. = 3·3–3·35; easily fusible.

The jade of China belongs to both species, so also that of the Swiss lake-habitations and of Mexico. Of the two, however, the former, nephrite, is the more common and makes the jade (ax-stone or Punamu stone) of the Maoris of New Zealand; also found in Alaska.

The name jade is also sometimes loosely used to embrace other minerals of more or less similar characters, and which have been or might be similarly used—thus sillimanite, pectolite, serpentine; also vesuvianite, garnet. Cf. remarks under these species. Bowenite is a jade-like variety of serpentine. The "jade tenace" of de Saussure is now called saussurite.

**Pyr., etc.**—In the matrass no change. B.B. fuses easily on the edges; with some soda, a blebby glass; with more, swells up and is infusible. With hydrochloric acid decomposed with separation of silica; most varieties effervesce slightly from the presence of calcite.

**Obs.**—Wollastonite is found especially in granular limestone, and in regions of granite; as a contact formation or in ejected masses in connection with basalt and lavas. It is often associated with a lime garnet, pyroxene, etc.

Occurs in the copper mines of Cziklowa in the Banat; at Orawitza; at Dognaczka and Nagyág; accompanying garnet, fluorite, and native silver, in limestone, at Pargas in Finland, and Kongsberg in Norway; occurs at Perhoniemi and Skräbböle, Finland; at Göckum in Sweden; at Vilna in Lithuania (vilnite); at Harzburg in the Harz; at Auerbach, in granular limestone; in the phonolyte of the Kaiserstuhl; at Vesuvius, rarely in fine crystals: of a greenish white color in lava at Capo di Bove, near Rome; S. Vito, Sarrabus, Sardinia; on Elba; Merida, Portugal; in recent lava on Santorin; in Ireland, at Dunmore Head, Mourne Mts.

In the United States, in *N. York*, at Willsborough, forming the sides of a large vein of garnet, traversing gneiss; at Lewis, 10 m. south of Keeseville, with colophonite, abundant; ½ m. N. of Lewis Corners, with garnet and quartz; at Roger's Rock, near the line between Essex and

Warren Cos., with garnet and feldspar; Diana, Lewis Co., about 1 m. from the Natural Bridge, in abundance, in large white crystals; at Booneville, Oneida Co., in boulders, with garnet and pyroxene; Bonaparte Lake, Lewis Co., in massive forms, fibrous to compact. In *Penn.*, Bucks Co., 3 m. W. of Attleboro', associated with scapolite, pyroxene, and titanite. In *Mich.*, of a red color at the Cliff Mine, Keweenaw Point, Lake Superior, and on Isle Royale, a very tough variety, but now exhausted. In *Canada*, at Grenville, with titanite and green coccolite; at St. Jérôme and Morin, Quebec, with apatite, in large tabular masses of a fibrous structure.

Named after the English chemist, W. H. Wollaston (1766–1828); also called *tabular spar* from its lamellar forms and structure.

The *soda-tabular spar* of Thomson, from near Kilsyth, is pectolite.

**Artif.**—Reported as observed occasionally in furnace slags, also repeatedly stated to have been formed artificially, but the correctness of the observations is doubtful, since in most cases the calcium silicate ($CaSiO_3$) observed does not agree with wollastonite crystallographically, but with the hexagonal compound noted below. For a review of the subject see Bourgeois, Reprod. Min., 113, 1884; Vogt, Arch. Math. Nat. Christiania, **30**, 66, 1889.

**Ref.**—[1]Mt. Somma, Pogg., **138**, 484, 1869. If (as in 5th Ed., p. 210) *α* be made 001, then since *cα* = 69° 56′, the resemblance to pyroxene comes out more clearly; but as urged by Rath the differences in cleavage, etc., are too great to recommend this. With Mlr. and Dx., *a*, *c*, *m*, *e* of Rath-Dana correspond to 001 (*c*), 201 (*u*), 011 (*e*), $\bar{2}21$ (*g*); cf. Hbg., Min. Not., **9**, 28, 1870. [2] See Mlr., Min., 288, 1852; Dx., Min., **1**, 49, 1862; also Rath, Hbg., l. c.

EDELFORSITE Kalksilikat fr. Ædelfors, Kalktrisilikat, *Hisinger*, Ak. H. Stockh., 191, 1838, 1839. Edelforsit *Kbl.*, Grundz., 202, 1838. Ædelforsit *Erdmann*. Forchhammer has shown (Danske Ak. Förh., Ap. 1864) that Hisinger's mineral is an impure wollastonite, containing some quartz and feldspar, with often carbonate of lime and garnet. It occurs compact, part feathery fibrous, and part without any distinct crystalline structure. Color white, grayish white, or with a tinge of yellow. From Ædelfors in Småland, Sweden.

The edelforsite of Gjellebäk (called Gillebäckit by N. Nordenskiöld, Atom. Ch. Min. Syst., 96, 1848) in Norway has also been shown by Forchhammer to be essentially wollastonite. It has the aspect of tremolite. Forchhammer has found "okenite" of N. Greenland (Asbestartig Okenit *Dr. Rink*) to be wollastonite.

HEXAGONAL CALCIUM METASILICATE. An artificial compound having the composition $CaSiO_3$, like wollastonite, but hexagonal in form and sometimes in tabular crystals, optically +, has been repeatedly obtained. Cf. Doelter, Jb. Min., **1**, 119, 1886; Vogt, Arch. Math. Nat., Krist., **30**, 57, 1889; Hussak, Vh. Ver. Rheinl., Corr., 95, 1887.

**Pyr., etc.**—In the closed tube yields water. B.B. fuses at 2 to a white enamel. Decomposed partially by hydrochloric acid, gelatinizing. Often gives out light when broken in the dark.

**Obs.**—Occurs mostly in basic eruptive rocks, in cavities or seams; occasionally in metamorphic rocks. Found in Scotland at Ratho Quarry and Castle Rock, near Edinburgh; at Kilsyth, Corstorphine Hill (*walkerite*), Loch End, Girvan, and Knockdolian Hill, in Ayrshire; and at Talisker, etc., I. Skye. Also at Mt. Baldo and Mt. Monzoni in the Tyrol, where first obtained; at an iron mine in Wermland, associated with chlorite and calcite. Disco Is., Greenland (so-called okenite).

Occurs also at Bergen Hill, N. J., in large and beautiful radiations; Lehigh county, Penn.; compact at Isle Royale, L. Superior; at Magnet Cove, Ark., in elæolite-syenite (*manganpectolite*); compact, massive in Alaska, where it is used, like jade, for implements.

$ap = 49° 7'$
$a's = 73° 31'$
$pp' = 51° 52'$
$ss' = 67° 22\frac{1}{2}'$
$ii = 88° 24\frac{1}{2}'$
$\phi\phi' = 106° 15'$
$\xi\xi' = 36° 52'$
$\pi\pi' = 51° 34'$

Crystals commonly prismatic and tabular ∥ *a*; usually twins, tw. pl. *a*; also with enclosed tw. lamellæ. Also granular.

Cleavage: *b* distinct. Fracture conchoidal to splintery. Brittle. H. = 5·5–6. G. = 3·41–3·44. Luster vitreous, inclining to resinous. Color light yellow, wine-, honey-, resin-yellow, brownish, grayish. Streak-powder yellowish white. Transparent to subtranslucent.

Pleochroism distinct, but not strong; $\mathfrak{c}$ wine-yellow, $\mathfrak{b}$ clear yellow, $\mathfrak{a}$ nearly colorless. Absorption $\mathfrak{c} > \mathfrak{b} = \mathfrak{a}$. Optically −. Ax. pl. nearly ∥ *d* (101) and ⊥ *b*. $Bx_a \wedge \grave{c} = -45°$. $Bx_o \perp b$. Dispersion small, $\rho < v$. Axial angles variable even in the same crystal, Dx.

| | | | | | |
|---|---|---|---|---|---|
| 1. | $2H_{a.r} = 89° 34'$ | $2H_{o.r} = 128° 6'$ | ∴ | $2V_r = 76° 10'$ | $\beta_r = 1{\cdot}67$ |
| | $2H_{a.bl} = 90° 54'$ | $2H_{o.bl} = 127° 6'$ | ∴ | $2V_{bl} = 77° 2'$ | $\beta_{bl} = 1{\cdot}69$ |
| 2. | $2H_{a.r} = 85° 41'$ | $2H_{o.r} = 139° 3'$ | ∴ | $2V_r = 71° 56'$ | $\beta_r = 1{\cdot}69$ |
| | $2H_{a.bl} = 86° 12'$ | $2H_{o.bl} = 138° 32'$ | ∴ | $2V_{bl} = 72° 18'$ | $\beta_{bl} = 1{\cdot}71$ |
| 3. | $2H_{a.r} = 86° 24'$ | $2H_{o.r} = 144° 24'$ | ∴ | $2V_r = 71° 26'$ | $\beta_r = 1{\cdot}72$ |
| | $2H_{a.bl} = 87° 30'$ | $2H_{o.bl} = 144° 8'$ | ∴ | $2V_{bl} = 72° 1'$ | $\beta_{bl} = 1{\cdot}74$ |

Also, Brögger, $Bx_a \wedge \grave{c} = -43° 18'$, and axial angles:

| | | | | |
|---|---|---|---|---|
| For Li | $2H_{a.r} = 90° 53'$ | $2H_{o.r} = 122° 9'$ | ∴ | $2V_r = 78° 18'$ |
| " Na | $2H_{a.y} = 91° 18'$ | $2H_{o.y} = 121° 42'$ | ∴ | $2V_y = 78° 37'$ |
| " Tl | $2H_{a.gr} = 91° 57'$ | $2H_{o.gr} = 121° 15'$ | ∴ | $2V_{gr} = 78° 49'$ |

**Comp.**—Essentially $12R(Si,Zr)O_3.RNb_2O_6$; where R = Ca : $Na_2$ = 4 : 1 nearly, also including Fe,Mn in small amount (Rg.). Further (Bgr.) with the metazirconate, $RZrO_3$, in part replaced by $RZr(O_2F_2)$.

**Anal.**—1, Scheerer, l. c. 2, Hermann, Bull. Soc. Moscow, **38**, 467, 1865. 3, Rammelsberg, Pogg., **150**, 211, 1873. 4, Cleve, Zs. Kr., **16**, 360, 1890.

| | | | | | | | | | | | | | X[a] 0·66 = 101·19 |

[a] X = Cerium oxides.

On the absorption spectra, see Krüss and Nilson, Öfv. Ak. Stockh., **44**, 369, 1887.

**Pyr., etc.**—B.B. in a strong heat fuses to a yellowish glass. With the fluxes gives the reactions of manganese, iron, and silica. Dissolves easily when heated in strong hydrochloric acid, with separation of the silica and niobium pentoxide.

**Obs.**—Occurs with elæolite, sodalite (and spreustein), cancrinite, barkevikite, ægirite, etc., in zircon-syenite, on several islands of the Langesund fiord, near Brevik, in Norway, especially on the island Skudesundskjär, near Barkevik; also on Lamöskjär (= Låven) and Stokö; further on the island Risö near Fredriksvärn. Some crystals are nearly an inch long. Named for Prof. Friedrich Wöhler (1800–1883).

**Ref.**—[1] Ann. Ch. Phys., **13**, 425, 1868; and earlier ib., **40**, 76, 1854; Ann. Mines, **16**, 229, 1859; Min., **1**, 162, 1862. See also Dbr., Pogg., **92**, 242, 1854; the system was at first supposed to be orthorhombic. Morton (quoted by Bgr., Zs. Kr., **16**, 355, 1890) gives: $\grave{a} : \bar{b} : \grave{c} = 1·0536 : 1 : 0·70878$; $\beta = 71° 3'$. [2] Cf. Dx., l. c., and Bgr., l. c. [3] Bgr.

## γ. *Triclinic Section.*

**334. HIORTDAHLITE.** *W. C. Brögger*, Nyt Mag., **31**, 232, 1889 (Separate, 1888); Zs. Kr., **16**, 367, 1890.

Triclinic. Axes $\breve{a} : \bar{b} : \grave{c} = 0·99835 : 1 : 0·35123$; $\alpha = 89° 22\frac{1}{2}'$, $\beta = 90° 36\frac{5}{6}'$, $\gamma = 90° 5\frac{5}{6}'$ Brögger.

$100 \wedge 010 = {}^*89° 54\frac{1}{2}'$, $100 \wedge 001 = 89° 23\frac{1}{4}'$, $010 \wedge 001 = 90° 37\frac{1}{2}'$.

**Forms:**
*a* (100, *i*-$\bar{i}$)
*b* (010, *i*-$\breve{i}$)
*l* (210, *i*-$\bar{2}'$)
*m* (110, *I'*)
*g* (120, *i*-$\breve{2}'$)
*h* ($2\bar{1}0$, '*i*-2)
*M* ($1\bar{1}0$, '*I*)
*k* ($1\bar{2}0$, '*i*-$\breve{2}$)
*v* (101, '1-$\bar{i}'$)
*p* (111, 1')
*g* ($\bar{1}\bar{1}1$, 1,)
*e* ($1\bar{1}1$, '1)
*x* (311, 3-$\bar{3}'$)
*y* ($\bar{3}\bar{1}1$, 3-$\bar{3}$,)
*z* ($3\bar{1}1$, '3-3)

*aM* = *44° 59½′
*mM* = 89° 53½′
*av* = 70° 4′
*ap* = 71° 1½′
*ae* = *71° 12′
*ax* = 44° 43′
*a′g* = 72° 11′
*bp* = 72° 14′
*b′e* = 71° 13½′
*Me* = *62° 53′
*pe* = 36° 33′
*ex* = *41° 31′

By inverting the crystals and taking *v* (101) as the base (001), Brögger calculates the following axial ratio and angles, which show the resemblance in form to wöhlerite:

$$\grave{a} : \bar{b} : \grave{c} = 1·0583 : 1 : 0·7048$$

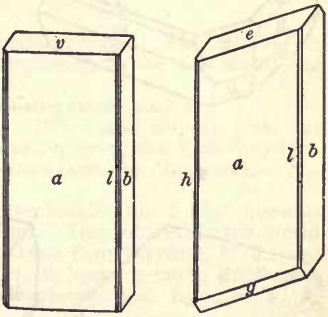
$$\alpha = 90° 29' \quad \beta = 108° 49\frac{1}{2}' \quad \gamma = 90° 8'.$$

Crystals tabular ‖ *a*, and vertically elongated; polysynthetic twins with twinning lamellæ having $\grave{c}$ as tw. ax., tw. pl. ⊥ $\grave{c}$ and comp.-face ‖ *a*.

Cleavage not distinct. Very brittle. H.=5–5·6. G. = 3·267 Bgr. Luster vitreous on crystalline faces; greasy on fracture surfaces. Color light shades of straw-, sulphur- to honey-yellow, less often yellowish brown.

Pleochroism not strongly marked: $\mathfrak{c}$ wine-yellow, $\mathfrak{b}$ bright yellow, $\mathfrak{a}$ nearly colorless. Absorption $\mathfrak{c} > \mathfrak{b} > \mathfrak{a}$. Optically +. $Bx_a$ situated in the upper left-hand front octant, oblique to *a*; the optic normal in that behind. Ax. pl. approximately ‖ $1\bar{1}1$. Extinction-angles with $\grave{c}$, on *a* = 25° and 65°, on *b* = 15½° and 74½°.

1. 2.



Norway, Brögger.

**Comp.**—Essentially $(Na_2,Ca)(Si,Zr)O_3$, with also fluorine present (Bgr.) as a fluozirconate $RZrO_2F_2$; nearly corresponding to $4Ca(Si,Zr)O_3.Na_2ZrO_2F_2$.

**Anal.**—Cleve, Zs. Kr., **16**, 374, 1890.

| | $SiO_2$ | $ZrO_2$ | $TiO_2$ | $Fe_2O_3$ | FeO | MnO | CaO | MgO | $Na_2O$ | $H_2O$ | F | |

The similarity in form between pyroxene and the triclinic species, rhodonite and babingtonite, is shown by their axial ratios and axial angles (pp. 344, 345); also by the following:

| | $110 \wedge 1\bar{1}0$ | $100 \wedge 001$ | $\bar{2}21 \wedge \bar{2}\bar{2}1$ | $221 \wedge 2\bar{2}1$ |
|---|---|---|---|---|
| Pyroxene | *mm‴* = 92° 50′ | *ac* = 74° 10′ | *oo′* = 84° 11′ | *vv′* = 68° 42 |
| Rhodonite | *mM* = 92° 28½′ | *ac* = 72° 36½′ | *kn* = 86° 5′ | |
| Babingtonite | *mM* = 92° 36′ | *ac* = 72° 29′ | | *hd* = 69° 21′ |

Crystals usually large and rough with rounded edges. Commonly tabular ‖ *c*; often elongated in direction of *M*, less often of *m*; also spear-shaped (f. 6); sometimes resembling pyroxene in habit, as in f. 5. Commonly massive, cleavable to compact; also in embedded grains.

Cleavage: *m*, *M* perfect; *c* less perfect. Fracture conchoidal to uneven; very tough when compact. H. = 5·5–6·5. G. = 3·4–3·68. Luster vitreous; on cleavage surfaces somewhat pearly. Color light brownish red, flesh-red, rose-pink; sometimes greenish or yellowish, when impure; often black outside from exposure. Streak white. Transparent to translucent.

Optically −. Extinction-angles on *a* (100), inclined 32° 26′ and 44° 16′ to edges *a*/*m* and *a*/*c* respectively; on *b*, inclined 10° 48′ and 97° 56′ to edges *b*/*a* and *b*/*c*; on *c*, inclined 54° 26½′ and 39° 37′ to edges *c*/*m* and *c*/*M*. Ax. pl. forms angles of 63° and 38½° with the planes *M* and *c*. Plane ⊥ $Bx_a$ inclined 51° 47′ and 51° 40′ to the same planes. Dispersion $\rho < v$. Axial angles, Flink:

$2H_{a.r}$ = 79° 25′ $2H_{o.r}$ = 109° 56′ ∴ $2V_{a.r}$ = 75° 57′ Li
$2H_{a.y}$ = 79° 0′ $2H_{o.y}$ = 108° 25′ ∴ $2V_{a.y}$ = 76° 12′ Na
$2H_{a.gr}$ = 78° 38½′ $2H_{o.gr}$ = 107° 13½′ ∴ $2V_{a.gr}$ = 76° 22′ Tl

**Comp., Var.**—Manganese metasilicate, $MnSiO_3$ or $MnO.SiO_2$ = Silica 45·9, manganese protoxide 54·1 = 100. Iron, calcium, and occasionally zinc replace part of the manganese.

1. *Ordinary*. (*a*) Crystallized. Either in crystals or cleavable masses. The mineral in crystals from Pajsberg, Sweden, was named *paisbergite* (or pajsbergite) under the idea that it was a distinct species. (*b*) Granular massive to compact.

2. *Ferriferous*. Contains sometimes nearly as much iron as manganese, anal. 9.

3. *Calciferous;* BUSTAMITE. Contains 9 to 20 p. c. of lime. Often also impure from the presence of calcium carbonate, which suggests that part of the lime replacing the MnO may have come from partial alteration. Grayish red. Named after M. Bustamente, the discoverer. The original was from Mexico.

4. *Zinciferous;* FOWLERITE. In crystals and foliated, the latter looking much like cleavable red feldspar; the crystals sometimes half an inch to an inch through. This mineral is mentioned by Fowler in Am. J. Sc., **9**, 245, 1825, as *siliceous oxyd of manganese* from Sterling, N. J., and as often containing dysluite (zinciferous spinel). It occurs under the same name in Robinson's Cat. Amer. Min., 298, 1825. It is Thomson's *ferrosilicate of manganese*, Ann. Lyc., N. Y., **3**, 28, 1828. Named after Dr. Samuel Fowler.

**Pyr., etc.**—B.B. blackens and fuses with slight intumescence at 2·5; with the fluxes gives reactions for manganese; fowlerite gives with soda on charcoal a reaction for zinc. Slightly acted upon by acids. The calciferous varieties often effervesce from mechanical admixture with calcium carbonate. In powder, partly dissolves in hydrochloric acid, and the insoluble part becomes of a white color. Darkens on exposure to the air, and sometimes becomes nearly black.

**Obs.**—Occurs at Långban, Wermland, Sweden, in iron ore beds, in broad cleavage plates, and also granular massive; at the Pajsberg iron mines near Filipstad (*paisbergite*) sometimes in small brilliant crystals; also at Elbingerode, in the Harz; in the district of Ekaterinburg in the Ural massive like marble, whence it is obtained for ornamental purposes; with tetrahedrite at Kapnik and Rezbánya, Hungary; in Cornwall; St. Marcel, also near Viu, Piedmont; Algiers; Tetela di Xonotla, Mexico.

Occurs in Cummington, Mass., and some of the neighboring towns, in boulders; also in Warwick, Mass.; in an extensive bed on Osgood's farm, Blue Hill Bay, Maine; in Irasburg and Coventry, Vt.; near Winchester and Hinsdale, N. H.; at Cumberland, R. I.; *fowlerite* at Mine Hill, Franklin Furnace, and Stirling Hill, near Ogdensburgh, N. J., the two localities only 2 or 3 miles apart, it is usually embedded in calcite and is sometimes in splendid crystallizations.

Named from *ῥόδον, a rose,* in allusion to the color. The name is attributed to Jasche by Germar (1819), but is not in the Kleine Min., Schriften of Jasche (1817).

**Alt.**—There are two prominent methods of alteration, which may act separately or together. (1) Through the strong tendency of manganese protoxide to pass to a higher state of oxidation; in which process the red color changes to brown or black, commencing with the exterior, which becomes a black crust to the mass. Indefinite mixtures thus result, which may be either partly silicate, or wholly one or more oxides of manganese. (2) Through the tendency of the manganese protoxide and other protoxides present to unite with carbonic acid afforded by alkaline carbonated waters, this causing the silicate to be penetrated with manganese carbonate, and often also with carbonate of lime or iron. The color of the result after this latter method is usually grayish red to grayish white, and sometimes brown.

I. *By Oxidation; not Hydrated or Carbonated.*

A. MARCELINE *Berthier,* Ann. Ch. Phys., **51**, 79, 1832. Color grayish black to iron-black; luster submetallic; G. = 3·8; H. = 5·5–6. From St. Marcel in Piedmont. *Heteroclin* Breith. (*Evreinov,* Pogg., **49**, 204, 1840) is from the same locality, and of the same nature, as recognized by Breithaupt.

B. DYSSNITE *v. Kobell,* Grundz., 328, 1838. Thomson's *sesquisilicate of M.,* from Franklin, N. J. (Ann. Lyc. N. York, l. c.), an iron-black ore, with G. = 3·67; it is altered fowlerite. Von Kobell cites Thomson's analysis, and gives no description of his own.

II. *By Oxidation; Hydrated.*

STRATOPEITE, Wittingite, Neotocite, are names of results of this kind of alteration. They are found along with rhodonite. They contain about 35 p. c. of silica. See NEOTOCITE under HYDROUS SILICATES. Opsimose of Beudant and Klipsteinite of v. Kobell (see beyond) are names of a similar hydrous silicate containing about 25 p. c. of silica, with admixed wad.

III. *Carbonated.*

A. ALLAGITE *Jasche,* Germar, Schw. J., **26**, 112, 1819; Grünmanganerz *Jasche,* Kleine Min. Schriften, 10, 1817. From Schebenholze, near Elbingerode in the Harz, is either dull green or reddish brown, and affording du Menil (Gilb. Ann., **61**, 199, 1819) 7·5 p. c. $CO_2$.

B. PHOTICITE *Germar,* Schw. J., **26**, 116, 1819; Photizit *Brandes,* ib., 138. Yellowish white, isabella- and wax-yellow, greenish gray, pearl-gray, to rose-red; G. = 2·8–3, from the same locality with the allagite. It afforded Brandes (ib., 136) 11 to 14 p. c. of carbon dioxide, with some water. Corneous manganese (*Horn-mangan* of Jasche) is of similar nature. it containing 5 to 10 p. c. of carbon dioxide; color brown to gray. And so also the Cummington rhodonite, which afforded Schlieper 10 p. c. or more of carbonates, and which Hermann erroneously made a manganesian amphibole.

Anal.—1, Berthier, l. c. 2, Damour, Ann. Mines, **1**, 400, 1842. 3, Thomson, Lyc. Nat. Hist., N. Y., **3**, 33. 4, 5, du Menil, l. c. 6-8, Brandes, l. c.
